- b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

For more information, see [Using S3 Object Lock](#).

 ⓘ Note

To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning` and `s3:PutBucketObjectLockConfiguration`.

14. Choose **Create bucket**.

Using the AWS CLI

To set Object Ownership when you create a new bucket, use the `create-bucket` AWS CLI command with the `--object-ownership` parameter.

This example applies the Bucket owner enforced setting for a new bucket using the AWS CLI:

```
aws s3api create-bucket --bucket DOC-EXAMPLE-BUCKET --region us-east-1 --object-ownership BucketOwnerEnforced
```

⚠️ Important

If you don't set Object Ownership when you create a bucket by using the AWS CLI, the default setting will be `ObjectWriter` (ACLs enabled).

Using the AWS SDK for Java

This example sets the Bucket owner enforced setting for a new bucket using the AWS SDK for Java:

```
// Build the ObjectOwnership for CreateBucket
CreateBucketRequest createBucketRequest = CreateBucketRequest.builder()
    .bucket(bucketName)
    .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
    .build()

// Send the request to Amazon S3
s3client.createBucket(createBucketRequest);
```

Using AWS CloudFormation

To use the AWS::S3::Bucket AWS CloudFormation resource to set Object Ownership when you create a new bucket, see [OwnershipControls within AWS::S3::Bucket](#) in the *AWS CloudFormation User Guide*.

Using the REST API

To apply the Bucket owner enforced setting for S3 Object Ownership, use the [CreateBucket](#) API operation with the `x-amz-object-ownership` request header set to `BucketOwnerEnforced`. For information and examples, see [CreateBucket](#) in the *Amazon Simple Storage Service API Reference*.

Next steps: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- [Bucket owner enforced](#) – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.
- [Bucket owner preferred](#) – Add an S3 bucket policy to require the `bucket-owner-full-control` canned ACL for all object uploads to your bucket.

Setting Object Ownership on an existing bucket

You can configure S3 Object Ownership on an existing S3 bucket. To apply Object Ownership when you create a bucket, see [Setting Object Ownership when you create a bucket](#).

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the

bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Prerequisites: Before you apply the Bucket owner enforced setting to disable ACLs, you must migrate bucket ACL permissions to bucket policies and reset your bucket ACLs to the default private ACL. We also recommend that you migrate object ACL permissions to bucket policies and edit bucket policies that require ACLs other than bucket owner full control ACLs. For more information, see [Prerequisites for disabling ACLs](#).

Permissions: To use this operation, you must have the `s3:PutBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see [Actions, resources, and condition keys for Amazon S3](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to apply an S3 Object Ownership setting to.
3. Choose the **Permissions** tab.
4. Under **Object Ownership**, choose **Edit**.

5. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

ACLs disabled

- **Bucket owner enforced** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

To require that all new buckets are created with ACLs disabled by using IAM or AWS Organizations policies, see [Disabling ACLs for all new buckets \(bucket owner enforced\)](#).

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

If you apply the bucket owner preferred setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can [add a bucket policy](#) that only allows object uploads that use this ACL.

- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

6. Choose **Save**.

Using the AWS CLI

To apply an Object Ownership setting for an existing bucket, use the `put-bucket-ownership-controls` command with the `--ownership-controls` parameter. Valid values for ownership are `BucketOwnerEnforced`, `BucketOwnerPreferred`, or `ObjectWriter`.

This example applies the Bucket owner enforced setting for an existing bucket by using the AWS CLI:

```
aws s3api put-bucket-ownership-controls --bucket DOC-EXAMPLE-BUCKET --ownership-controls="Rules=[{ObjectOwnership=BucketOwnerEnforced}]"
```

For information about `put-bucket-ownership-controls`, see [put-bucket-ownership-controls](#) in the *AWS Command Line Interface User Guide*.

Using the AWS SDK for Java

This example applies the `BucketOwnerEnforced` setting for Object Ownership on an existing bucket by using the AWS SDK for Java:

```
// Build the ObjectOwnership for BucketOwnerEnforced
OwnershipControlsRule rule = OwnershipControlsRule.builder()
    .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
    .build();

OwnershipControls ownershipControls = OwnershipControls.builder()
    .rules(rule)
    .build()

// Build the PutBucketOwnershipControlsRequest
PutBucketOwnershipControlsRequest putBucketOwnershipControlsRequest =
    PutBucketOwnershipControlsRequest.builder()
        .bucket(BUCKET_NAME)
        .ownershipControls(ownershipControls)
        .build();

// Send the request to Amazon S3
s3client.putBucketOwnershipControls(putBucketOwnershipControlsRequest);
```

Using AWS CloudFormation

To use AWS CloudFormation to apply an Object Ownership setting for an existing bucket, see [AWS::S3::Bucket OwnershipControls](#) in the *AWS CloudFormation User Guide*.

Using the REST API

To use the REST API to apply an Object Ownership setting to an existing S3 bucket, use `PutBucketOwnershipControls`. For more information, see [PutBucketOwnershipControls](#) in the *Amazon Simple Storage Service API Reference*.

Next steps: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- [Bucket owner enforced](#) – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.
- [Bucket owner preferred](#) – Add an S3 bucket policy to require the `bucket-owner-full-control` canned ACL for all object uploads to your bucket.

Viewing the Object Ownership setting for an S3 bucket

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

You can view the S3 Object Ownership settings for an Amazon S3 bucket. To set Object Ownership for a new bucket, see [Setting Object Ownership when you create a bucket](#). To set Object Ownership for an existing bucket, see [Setting Object Ownership on an existing bucket](#).

Permissions: To use this operation, you must have the `s3:GetBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see [Actions, resources, and condition keys for Amazon S3](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the **Buckets** list, choose the name of the bucket that you want to apply an Object Ownership setting to.
3. Choose the **Permissions** tab.
4. Under **Object Ownership**, you can view the Object Ownership settings for your bucket.

Using the AWS CLI

To retrieve the S3 Object Ownership setting for an S3 bucket, use the [get-bucket-ownership-controls](#) AWS CLI command.

```
aws s3api get-bucket-ownership-controls --bucket DOC-EXAMPLE-BUCKET
```

Using the REST API

To retrieve the Object Ownership setting for an S3 bucket, use the `GetBucketOwnershipControls` API operation. For more information, see [GetBucketOwnershipControls](#).

Disabling ACLs for all new buckets and enforcing Object Ownership

We recommend that you disable ACLs on your Amazon S3 buckets. You can do this by applying the Bucket owner enforced setting for S3 Object Ownership. When you apply this setting, ACLs are disabled and you automatically own and have full control over all objects in your bucket. To require that all new buckets are created with ACLs disabled, use AWS Identity and Access Management (IAM) policies or AWS Organizations service control policies (SCPs), as described in the next section.

To enforce object ownership for new objects without disabling ACLs, you can apply the Bucket owner preferred setting. When you apply this setting, we strongly recommend that you update your bucket policy to require the `bucket-owner-full-control` canned ACL for all PUT requests to your bucket. Make sure you also update your clients to send the `bucket-owner-full-control` canned ACL to your bucket from other accounts.

Topics

- [Disabling ACLs for all new buckets \(bucket owner enforced\)](#)
- [Requiring the `bucket-owner-full-control` canned ACL for Amazon S3 PUT operations \(bucket owner preferred\)](#)

Disabling ACLs for all new buckets (bucket owner enforced)

The following example IAM policy denies the `s3:CreateBucket` permission for a specific IAM user or role unless the Bucket owner enforced setting is applied for Object Ownership. The key-value pair in the Condition block specifies `s3:x-amz-object-ownership` as its key and the `BucketOwnerEnforced` setting as its value. In other words, the IAM user can create buckets only if they set the Bucket owner enforced setting for Object Ownership and disable ACLs. You can also use this policy as a boundary SCP for your AWS organization.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "RequireBucketOwnerFullControl",  
            "Action": "s3:CreateBucket",  
            "Effect": "Deny",  
            "Resource": "*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:x-amz-object-ownership": "BucketOwnerEnforced"  
                }  
            }  
        }  
    ]  
}
```

Requiring the bucket-owner-full-control canned ACL for Amazon S3 PUT operations (bucket owner preferred)

With the Bucket owner preferred setting for Object Ownership, you, as the bucket owner, own and have full control over new objects that other accounts write to your bucket with the `bucket-owner-full-control` canned ACL. However, if other accounts write objects to your bucket without the `bucket-owner-full-control` canned ACL, the object writer maintains full control access. You, as the bucket owner, can implement a bucket policy that allows writes only if they specify the `bucket-owner-full-control` canned ACL.

Note

If you have ACLs disabled with the Bucket owner enforced setting, you, as the bucket owner, automatically own and have full control over all the objects in your bucket. You

don't need to use this section to update your bucket policy to enforce object ownership for the bucket owner.

The following bucket policy specifies that account **111122223333** can upload objects to **DOC-EXAMPLE-BUCKET** only when the object's ACL is set to `bucket-owner-full-control`. Be sure to replace **111122223333** with your account and **DOC-EXAMPLE-BUCKET** with the name of your bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Only allow writes to my bucket with bucket owner full control",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/ExampleUser"  
                ]  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-acl": "bucket-owner-full-control"  
                }  
            }  
        }  
    ]  
}
```

The following is an example copy operation that includes the `bucket-owner-full-control` canned ACL by using the AWS Command Line Interface (AWS CLI).

```
aws s3 cp file.txt s3://DOC-EXAMPLE-BUCKET --acl bucket-owner-full-control
```

After the bucket policy is put into effect, if the client does not include the `bucket-owner-full-control` canned ACL, the operation fails, and the uploader receives the following error:

An error occurred (AccessDenied) when calling the PutObject operation: Access Denied.

Note

If clients need access to objects after uploading, you must grant additional permissions to the uploading account. For information about granting accounts access to your resources, see [Example walkthroughs: Managing access to your Amazon S3 resources](#).

Troubleshooting

When you apply the Bucket owner enforced setting for S3 Object Ownership, access control lists (ACLs) are disabled and you, as the bucket owner, automatically own all objects in your bucket. ACLs no longer affect permissions for the objects in your bucket. You can use policies to grant permissions. All S3 PUT requests must either specify the bucket-owner-full-control canned ACL or not specify an ACL, or these requests will fail. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

If an invalid ACL is specified or bucket ACL permissions grant access outside of your AWS account, you might see the following error responses.

AccessControlListNotSupported

After you apply the Bucket owner enforced setting for Object Ownership, ACLs are disabled. Requests to set ACLs or update ACLs fail with a 400 error and return the AccessControlListNotSupported error code. Requests to read ACLs are still supported. Requests to read ACLs always return a response that shows full control for the bucket owner. In your PUT operations, you must either specify bucket owner full control ACLs or not specify an ACL. Otherwise, your PUT operations fail.

The following example put-object AWS CLI command includes the public-read canned ACL.

```
aws s3api put-object --bucket DOC-EXAMPLE-BUCKET --key object-key-name --body doc-example-body --acl public-read
```

If the bucket uses the Bucket owner enforced setting to disable ACLs, this operation fails, and the uploader receives the following error message:

An error occurred (AccessControlListNotSupported) when calling the PutObject operation: The bucket does not allow ACLs

InvalidBucketAclWithObjectOwnership

If you want to apply the Bucket owner enforced setting to disable ACLs, your bucket ACL must give full control only to the bucket owner. Your bucket ACL cannot give access to an external AWS account or any other group. For example, if your `CreateBucket` request sets Bucket owner enforced and specifies a bucket ACL that provides access to an external AWS account, your request fails with a `400` error and returns the `InvalidBucketAclWithObjectOwnership` error code. Similarly, if your `PutBucketOwnershipControls` request sets Bucket owner enforced on a bucket that has a bucket ACL that grants permissions to others, the request fails.

Example : Existing bucket ACL grants public read access

For example, if an existing bucket ACL grants public read access, you cannot apply the Bucket owner enforced setting for Object Ownership until you migrate these ACL permissions to a bucket policy and reset your bucket ACL to the default private ACL. For more information, see [Prerequisites for disabling ACLs](#).

This example bucket ACL grants public read access:

```
{  
    "Owner": {  
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"  
    },  
    "Grants": [  
        {  
            "Grantee": {  
                "ID": "  
852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",  
                "Type": "CanonicalUser"  
            },  
            "Permission": "FULL_CONTROL"  
        },  
        {  
            "Grantee": {  
                "Type": "Group",  
                "URI": "http://acs.amazonaws.com/groups/global/AllUsers"  
            },  
            "Permission": "READ"  
        }  
    ]  
}
```

The following example `put-bucket-ownership-controls` AWS CLI command applies the Bucket owner enforced setting for Object Ownership:

```
aws s3api put-bucket-ownership-controls --bucket DOC-EXAMPLE-BUCKET --ownership-controls Rules=[{ObjectOwnership=BucketOwnerEnforced}]
```

Because the bucket ACL grants public read access, the request fails and returns the following error code:

An error occurred (InvalidBucketAclWithObjectOwnership) when calling the PutBucketOwnershipControls operation: Bucket cannot have ACLs set with ObjectOwnership's BucketOwnerEnforced setting

Logging and monitoring in Amazon S3

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon S3 resources and responding to potential incidents.

For more information, see [Monitoring Amazon S3](#).

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [What is S3 Express One Zone?](#) and [Directory buckets](#).

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring metrics with Amazon CloudWatch](#).

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon S3. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

Amazon S3 Access Logs

Server access logs provide detailed records about requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. For more information, see [Logging requests with server access logging](#).

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon S3-related checks:

- Logging configuration of Amazon S3 buckets.
- Security checks for Amazon S3 buckets that have open access permissions.
- Fault tolerance checks for Amazon S3 buckets that don't have versioning enabled, or have versioning suspended.

For more information, see [AWS Trusted Advisor](#) in the *AWS Support User Guide*.

The following security best practices also address logging and monitoring:

- [Identify and audit all your Amazon S3 buckets](#)
- [Implement monitoring using Amazon Web Services monitoring tools](#)
- [Enable AWS Config](#)
- [Enable Amazon S3 server access logging](#)
- [Use CloudTrail](#)
- [Monitor Amazon Web Services security advisories](#)

Compliance Validation for Amazon S3

The security and compliance of Amazon S3 is assessed by third-party auditors as part of multiple AWS compliance programs, including the following:

- System and Organization Controls (SOC)
- Payment Card Industry Data Security Standard (PCI DSS)
- Federal Risk and Authorization Management Program (FedRAMP)
- Health Insurance Portability and Accountability Act (HIPAA)

AWS provides a frequently updated list of AWS services in scope of specific compliance programs at [AWS Services in Scope by Compliance Program](#).

Third-party audit reports are available for you to download using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#).

For more information about AWS compliance programs, see [AWS Compliance Programs](#).

Your compliance responsibility when using Amazon S3 is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. If your use of Amazon S3 is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- [Security and Compliance Quick Start Guides](#) that discuss architectural considerations and steps for deploying security- and compliance-focused baseline environments on AWS.
- [Architecting for HIPAA Security and Compliance](#) outlines how companies use AWS to help them meet HIPAA requirements.
- [AWS Compliance Resources](#) provide several different workbooks and guides that might apply to your industry and location.
- [AWS Config](#) can be used to assess how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub](#) provides you with a comprehensive view of your security state within AWS and helps you check your compliance with security industry standards and best practices.
- [Using S3 Object Lock](#) can help you meet technical requirements of financial services regulators (such as the SEC, FINRA, and CFTC) that require write once, read many (WORM) data storage for certain types of books and records information.

- [Amazon S3 Inventory](#) can help you audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs.

Resilience in Amazon S3

The AWS global infrastructure is built around Regions and Availability Zones. AWS Regions provide multiple, physically separated and isolated Availability Zones that are connected with low latency, high throughput, and highly redundant networking. These Availability Zones offer you an effective way to design and operate applications and databases. They are more highly available, fault tolerant, and scalable than traditional single data center infrastructures or multi-data center infrastructures. If you specifically need to replicate your data over greater geographic distances, you can use [Replicating objects](#), which enables automatic, asynchronous copying of objects across buckets in different AWS Regions.

Each AWS Region has multiple Availability Zones. You can deploy your applications across multiple Availability Zones in the same Region for fault tolerance and low latency. Availability Zones are connected to each other with fast, private fiber-optic networking, enabling you to easily architect applications that automatically fail over between Availability Zones without interruption.

For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](#).

In addition to the AWS global infrastructure, Amazon S3 offers several features to help support your data resiliency and backup needs.

Lifecycle configuration

A lifecycle configuration is a set of rules that define actions that Amazon S3 applies to a group of objects. With lifecycle configuration rules, you can tell Amazon S3 to transition objects to less expensive storage classes, archive them, or delete them. For more information, see [Managing your storage lifecycle](#).

Versioning

Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. For more information, see [Using versioning in S3 buckets](#).

S3 Object Lock

You can use S3 Object Lock to store objects using a *write once, read many* (WORM) model. Using S3 Object Lock, you can prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. S3 Object Lock enables you to meet regulatory requirements

that require WORM storage or simply to add an additional layer of protection against object changes and deletion. For more information, see [Using S3 Object Lock](#).

Storage classes

Amazon S3 offers a range of storage classes to choose from depending on the requirements of your workload. The S3 Standard-IA and S3 One Zone-IA storage classes are designed for data you access about once a month and need milliseconds access. The S3 Glacier Instant Retrieval storage class is designed for long-lived archive data accessed with milliseconds access that you access about once a quarter. For archive data that does not require immediate access, such as backups, you can use the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For more information, see [Using Amazon S3 storage classes](#).

The following security best practices also address resilience:

- [Enable versioning](#)
- [Consider Amazon S3 cross-region replication](#)
- [Identify and audit all your Amazon S3 buckets](#)

Encryption of Amazon S3 backups

If you are storing backups using Amazon S3, the encryption of your backups depends on the configuration of those buckets. Amazon S3 provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The default encryption supports keys stored in AWS KMS (SSE-KMS). For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

For more information about Versioning and Object Lock, see the following topics: [Using versioning in S3 buckets](#) [Using S3 Object Lock](#)

Infrastructure security in Amazon S3

As a managed service, Amazon S3 is protected by the AWS global network security procedures that are described in the security pillar of the [AWS Well-Architected Framework](#).

Access to Amazon S3 via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend also supporting TLS 1.3. (For more information about this recommendation, see [Faster AWS cloud connections with TLS 1.3](#) on the *AWS Security Blog*.) Clients must also support cipher suites with Perfect Forward Secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Additionally, requests must be signed using AWS Signature V4 or AWS Signature V2, requiring valid credentials to be provided.

These APIs are callable from any network location. However, Amazon S3 does support resource-based access policies, which can include restrictions based on the source IP address. You can also use Amazon S3 bucket policies to control access to buckets from specific virtual private cloud (VPC) endpoints, or specific VPCs. Effectively, this isolates network access to a given Amazon S3 bucket from only the specific VPC within the AWS network. For more information, see [Controlling access from VPC endpoints with bucket policies](#).

The following security best practices also address infrastructure security in Amazon S3:

- [Consider VPC endpoints for Amazon S3 access](#)
- [Identify and audit all your Amazon S3 buckets](#)

Configuration and vulnerability analysis in Amazon S3

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- [Compliance Validation for Amazon S3](#)
- [Shared Responsibility Model](#)
- [Amazon Web Services: Overview of Security Processes](#)

The following security best practices also address configuration and vulnerability analysis in Amazon S3:

- [Identify and audit all your Amazon S3 buckets](#)
- [Enable AWS Config](#)

Security best practices for Amazon S3

Amazon S3 provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful recommendations rather than prescriptions.

Topics

- [Amazon S3 security best practices](#)
- [Amazon S3 monitoring and auditing best practices](#)

Amazon S3 security best practices

The following best practices for Amazon S3 can help prevent security incidents.

Disable access control lists (ACLs)

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively using access management policies.

A majority of modern use cases in Amazon S3 no longer require the use of [access control lists \(ACLs\)](#). We recommend that you disable ACLs, except in unusual circumstances where you must control access for each object individually. To disable ACLs and take ownership of every object in your bucket, apply the bucket owner enforced setting for S3 Object Ownership. When you disable ACLs, you can easily maintain a bucket with objects uploaded by different AWS accounts.

When ACLs are disabled access control for your data is based on policies, such as the following:

- AWS Identity and Access Management (IAM) user policies
- S3 bucket policies
- Virtual private cloud (VPC) endpoint policies
- AWS Organizations service control policies (SCPs)

Disabling ACLs simplifies permissions management and auditing. ACLs are disabled for new buckets by default. You can also disable ACLs for existing buckets. If you have an existing bucket that already has objects in it, after you disable ACLs, the object and bucket ACLs are no longer part of the access-evaluation process. Instead, access is granted or denied on the basis of policies.

Before you disable ACLs, make sure that you do the following:

- Review your bucket policy to ensure that it covers all the ways that you intend to grant access to your bucket outside of your account.
- Reset your bucket ACL to the default (full control to the bucket owner).

After you disable ACLs, the following behaviors occur:

- Your bucket accepts only PUT requests that do not specify an ACL or PUT requests with bucket owner full control ACLs. These ACLs include the `bucket-owner-full-control` canned ACL or equivalent forms of this ACL that are expressed in XML.
- Existing applications that support bucket owner full control ACLs see no impact.
- PUT requests that contain other ACLs (for example, custom grants to certain AWS accounts) fail and return an HTTP status code `400` (Bad Request) with the error code `AccessControlListNotSupported`.

For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Ensure that your Amazon S3 buckets use the correct policies and are not publicly accessible

Unless you explicitly require anyone on the internet to be able to read or write to your S3 bucket, make sure that your S3 bucket is not public. The following are some of the steps that you can take to block public access:

- Use S3 Block Public Access. With S3 Block Public Access, you can easily set up centralized controls to limit public access to your Amazon S3 resources. These centralized controls are enforced regardless of how the resources are created. For more information, see [Blocking public access to your Amazon S3 storage](#).
- Identify Amazon S3 bucket policies that allow a wildcard identity such as "Principal": "`*`" (which effectively means "anyone"). Also look for policies that allow a wildcard action "`*`" (which effectively allows the user to perform any action in the Amazon S3 bucket).
- Similarly, look for Amazon S3 bucket access control lists (ACLs) that provide read, write, or full-access to "Everyone" or "Any authenticated AWS user."

- Use the `ListBuckets` API operation to scan all of your Amazon S3 buckets. Then use `GetBucketAcl`, `GetBucketWebsite`, and `GetBucketPolicy` to determine whether each bucket has compliant access controls and a compliant configuration.
- Use [AWS Trusted Advisor](#) to inspect your Amazon S3 implementation.
- Consider implementing ongoing detective controls by using the [`s3-bucket-public-read-prohibited`](#) and [`s3-bucket-public-write-prohibited`](#) managed AWS Config Rules.

For more information, see [Identity and access management in Amazon S3](#).

Implement least privilege access

When granting permissions, you decide who is getting what permissions to which Amazon S3 resources. You enable specific actions that you want to allow on those resources. Therefore, we recommend that you grant only the permissions that are required to perform a task. Implementing least privilege access is fundamental in reducing security risk and the impact that could result from errors or malicious intent.

The following tools are available to implement least privilege access:

- [Amazon S3 actions](#) and [Permissions Boundaries for IAM Entities](#)
- [Bucket policies and user policies](#)
- [Access control list \(ACL\) overview](#)
- [Service Control Policies](#)

For guidance on what to consider when choosing one or more of the preceding mechanisms, see [Access policy guidelines](#).

Use IAM roles for applications and AWS services that require Amazon S3 access

In order for applications running on Amazon EC2 or other AWS services to access Amazon S3 resources, they must include valid AWS credentials in their AWS API requests. We recommend not storing AWS credentials directly in the application or Amazon EC2 instance. These are long-term credentials that are not automatically rotated and could have a significant business impact if they are compromised.

Instead, use an IAM role to manage temporary credentials for applications or services that need to access Amazon S3. When you use a role, you don't have to distribute long-term credentials (such as a username and password or access keys) to an Amazon EC2 instance or AWS service, such as AWS Lambda. The role supplies temporary permissions that applications can use when they make calls to other AWS resources.

For more information, see the following topics in the *IAM User Guide*:

- [IAM Roles](#)
- [Common Scenarios for Roles: Users, Applications, and Services](#)

Consider encryption of data at rest

You have the following options for protecting data at rest in Amazon S3:

- **Server-side encryption** – All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

Amazon S3 also provides these server-side encryption options:

- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

For more information, see [Protecting data with server-side encryption](#).

- **Client-side encryption** – Encrypt data client-side and upload the encrypted data to Amazon S3. In this case, you manage the encryption process, the encryption keys, and related tools. As with server-side encryption, client-side encryption can help reduce risk by encrypting the data with a key that is stored in a different mechanism than the mechanism that stores the data itself.

Amazon S3 provides multiple client-side encryption options. For more information, see [Protecting data by using client-side encryption](#).

Enforce encryption of data in transit

You can use HTTPS (TLS) to help prevent potential attackers from eavesdropping on or manipulating network traffic by using person-in-the-middle or similar attacks. We recommend allowing only encrypted connections over HTTPS (TLS) by using the [aws:SecureTransport](#) condition in your Amazon S3 bucket policies.

Also consider implementing ongoing detective controls by using the [s3-bucket-ssl-requests-only](#) managed AWS Config rule.

Consider using S3 Object Lock

With S3 Object Lock, you can store objects by using a "Write Once Read Many" (WORM) model. S3 Object Lock can help prevent accidental or inappropriate deletion of data. For example, you can use S3 Object Lock to help protect your AWS CloudTrail logs.

For more information, see [Using S3 Object Lock](#).

Enable S3 Versioning

S3 Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can easily recover from both unintended user actions and application failures.

Also consider implementing ongoing detective controls by using the [s3-bucket-versioning-enabled](#) managed AWS Config rule.

For more information, see [Using versioning in S3 buckets](#).

Consider using S3 Cross-Region Replication

Although Amazon S3 stores your data across multiple geographically diverse Availability Zones by default, compliance requirements might dictate that you store data at even greater distances. With S3 Cross-Region Replication (CRR), you can replicate data between distant AWS Regions to help satisfy these requirements. CRR enables automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see [Replicating objects](#).

 **Note**

CRR requires both the source and destination S3 buckets to have versioning enabled.

Also consider implementing ongoing detective controls by using the [s3-bucket-replication-enabled](#) managed AWS Config rule.

Consider using VPC endpoints for Amazon S3 access

A virtual private cloud (VPC) endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. VPC endpoints can help prevent traffic from traversing the open internet.

VPC endpoints for Amazon S3 provide multiple ways to control access to your Amazon S3 data:

- You can control the requests, users, or groups that are allowed through a specific VPC endpoint by using S3 bucket policies.
- You can control which VPCs or VPC endpoints have access to your S3 buckets by using S3 bucket policies.
- You can help prevent data exfiltration by using a VPC that does not have an internet gateway.

For more information, see [Controlling access from VPC endpoints with bucket policies](#).

Use managed AWS security services to monitor data security

Several managed AWS security services can help you identify, assess, and monitor security and compliance risks for your Amazon S3 data. These services can also help you protect your data from those risks. These services include automated detection, monitoring, and protection capabilities that are designed to scale from Amazon S3 resources for a single AWS account to resources for organizations spanning thousands of accounts.

For more information, see [Monitoring data security with managed AWS security services](#).

Amazon S3 monitoring and auditing best practices

The following best practices for Amazon S3 can help detect potential security weaknesses and incidents.

Identify and audit all of your Amazon S3 buckets

Identification of your IT assets is a crucial aspect of governance and security. You need to have visibility of all your Amazon S3 resources to assess their security posture and take action on potential areas of weakness. To audit your resources, we recommend doing the following:

- Use Tag Editor to identify and tag security-sensitive or audit-sensitive resources, then use those tags when you need to search for these resources. For more information, see [Searching for Resources to Tag](#) in the *Tagging AWS Resources User Guide*.
- Use S3 Inventory to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. For more information, see [Amazon S3 Inventory](#).
- Create resource groups for your Amazon S3 resources. For more information, see [What are resource groups?](#) in the *AWS Resource Groups User Guide*.

Implement monitoring by using AWS monitoring tools

Monitoring is an important part of maintaining the reliability, security, availability, and performance of Amazon S3 and your AWS solutions. AWS provides several tools and services to help you monitor Amazon S3 and your other AWS services. For example, you can monitor Amazon CloudWatch metrics for Amazon S3, particularly the PutRequests, GetRequests, 4xxErrors, and DeleteRequests metrics. For more information, see [Monitoring metrics with Amazon CloudWatch](#) and [Monitoring Amazon S3](#).

For a second example, see [Example: Amazon S3 Bucket Activity](#). This example describes how to create a CloudWatch alarm that is triggered when an Amazon S3 API call is made to PUT or DELETE a bucket policy, a bucket lifecycle, or a bucket replication configuration, or to PUT a bucket ACL.

Enable Amazon S3 server access logging

Server access logging provides detailed records of the requests that are made to a bucket. Server access logs can assist you in security and access audits, help you learn about your customer base, and understand your Amazon S3 bill. For instructions on enabling server access logging, see [Logging requests with server access logging](#).

Also consider implementing ongoing detective controls by using the [s3-bucket-logging-enabled](#) AWS Config managed rule.

Use AWS CloudTrail

AWS CloudTrail provides a record of actions taken by a user, a role, or an AWS service in Amazon S3. You can use information collected by CloudTrail to determine the following:

- The request that was made to Amazon S3
- The IP address from which the request was made
- Who made the request
- When the request was made
- Additional details about the request

For example, you can identify CloudTrail entries for PUT actions that affect data access, in particular PutBucketAcl, PutObjectAcl, PutBucketPolicy, and PutBucketWebsite.

When you set up your AWS account, CloudTrail is enabled by default. You can view recent events in the CloudTrail console. To create an ongoing record of activity and events for your

Amazon S3 buckets, you can create a trail in the CloudTrail console. For more information, see [Logging data events](#) in the *AWS CloudTrail User Guide*.

When you create a trail, you can configure CloudTrail to log data events. Data events are records of resource operations performed on or within a resource. In Amazon S3, data events record object-level API activity for individual buckets. CloudTrail supports a subset of Amazon S3 object-level API operations, such as `GetObject`, `DeleteObject`, and `PutObject`. For more information about how CloudTrail works with Amazon S3, see [Logging Amazon S3 API calls using AWS CloudTrail](#). In the Amazon S3 console, you can also configure your S3 buckets to [Enabling CloudTrail event logging for S3 buckets and objects](#).

AWS Config provides a managed rule (`cloudtrail-s3-dataevents-enabled`) that you can use to confirm that at least one CloudTrail trail is logging data events for your S3 buckets. For more information, see [cloudtrail-s3-dataevents-enabled](#) in the *AWS Config Developer Guide*.

Enable AWS Config

Several of the best practices listed in this topic suggest creating AWS Config rules. AWS Config helps you to assess, audit, and evaluate the configurations of your AWS resources. AWS Config monitors resource configurations so that you can evaluate the recorded configurations against the desired secure configurations. With AWS Config, you can do the following:

- Review changes in configurations and relationships between AWS resources
- Investigate detailed resource-configuration histories
- Determine your overall compliance against the configurations specified in your internal guidelines

Using AWS Config can help you simplify compliance auditing, security analysis, change management, and operational troubleshooting. For more information, see [Setting Up AWS Config with the Console](#) in the *AWS Config Developer Guide*. When specifying the resource types to record, ensure that you include Amazon S3 resources.

Important

AWS Config managed rules only supports general purpose buckets when evaluating Amazon S3 resources. AWS Config doesn't record configuration changes for directory buckets. For more information, see [AWS Config Managed Rules](#) and [List of AWS Config Managed Rules](#) in the *AWS Config Developer Guide*.

For an example of how to use AWS Config, see [How to Use AWS Config to Monitor for and Respond to Amazon S3 Buckets Allowing Public Access](#) on the [AWS Security Blog](#).

Discover sensitive data by using Amazon Macie

Amazon Macie is a security service that discovers sensitive data by using machine learning and pattern matching. Macie provides visibility into data security risks, and enables automated protection against those risks. With Macie, you can automate the discovery and reporting of sensitive data in your Amazon S3 data estate to gain a better understanding of the data that your organization stores in S3.

To detect sensitive data with Macie, you can use built-in criteria and techniques that are designed to detect a large and growing list of sensitive data types for many countries and regions. These sensitive data types include multiple types of personally identifiable information (PII), financial data, and credentials data. You can also use custom criteria that you define—regular expressions that define text patterns to match and, optionally, character sequences and proximity rules that refine the results.

If Macie detects sensitive data in an S3 object, Macie generates a security finding to notify you. This finding provides information about the affected object, the types and number of occurrences of the sensitive data that Macie found, and additional details to help you investigate the affected S3 bucket and object. For more information, see the [Amazon Macie User Guide](#).

Use S3 Storage Lens

S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

With S3 Storage Lens, you can use metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and access-management best practices, and improve the performance of application workloads.

For example, you can identify buckets that don't have S3 Lifecycle rules to abort incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. For more information, see [Understanding Amazon S3 Storage Lens](#).

Monitor AWS security advisories

We recommend that you regularly check the security advisories posted in Trusted Advisor for your AWS account. In particular, look for warnings about Amazon S3 buckets with "open access permissions." You can do this programmatically by using [describe-trusted-advisor-checks](#).

Further, actively monitor the primary email address that's registered to each of your AWS accounts. AWS uses this email address to contact you about emerging security issues that might affect you.

AWS operational issues with broad impact are posted on the [AWS Health Dashboard - Service health](#). Operational issues are also posted to individual accounts through the AWS Health Dashboard. For more information, see the [AWS Health documentation](#).

Monitoring data security with managed AWS security services

Several managed AWS security services can help you identify, assess, and monitor security and compliance risks for your Amazon S3 data. They can also help you protect your data from those risks. These services include automated detection, monitoring, and protection capabilities that are designed to scale from Amazon S3 resources for a single AWS account to resources for organizations spanning thousands of AWS accounts.

AWS detection and response services can help you identify potential security misconfigurations, threats, or unexpected behaviors, so that you can quickly respond to potentially unauthorized or malicious activity in your environment. AWS data protection services can help you monitor and protect your data, accounts, and workloads from unauthorized access. They can also help you discover sensitive data, such as personally identifiable information (PII), in your Amazon S3 data estate.

To help you identify and evaluate data security and compliance risks, managed AWS security services generate findings to notify you of potential security events or issues with your Amazon S3 data. The findings provide relevant details that you can use to investigate, assess, and act upon these risks according to your incident-response workflows and policies. You can access findings data directly by using each service. You can also send the data to other applications, services, and systems, such as your security incident and event management system (SIEM).

To monitor the security of your Amazon S3 data, consider using these managed AWS security services.

Amazon GuardDuty

Amazon GuardDuty is a threat-detection service that continuously monitors your AWS accounts and workloads for malicious activity and delivers detailed security findings for visibility and remediation.

With the S3 protection feature in GuardDuty, you can configure GuardDuty to analyze AWS CloudTrail management and data events for your Amazon S3 resources. GuardDuty then monitors those events for malicious and suspicious activity. To inform the analysis and identify potential security risks, GuardDuty uses threat-intelligence feeds and machine learning.

GuardDuty can monitor different kinds of activity for your Amazon S3 resources. For example, CloudTrail management events for Amazon S3 include bucket-level operations, such as `ListBuckets`, `DeleteBucket`, and `PutBucketReplication`. CloudTrail data events

for Amazon S3 include object-level operations, such as `GetObject`, `ListObjects`, and `PutObject`. If GuardDuty detects anomalous or potentially malicious activity, it generates a finding to notify you.

For more information, see [Amazon S3 Protection in Amazon GuardDuty](#) in the *Amazon GuardDuty User Guide*.

Amazon Detective

Amazon Detective simplifies the investigative process and helps you conduct faster, more effective security investigations. Detective provides prebuilt data aggregations, summaries, and context that can help you analyze and assess the nature and extent of possible security issues.

Detective automatically extracts time-based events, such as API calls from AWS CloudTrail and Amazon VPC Flow Logs for your AWS resources. It also ingests findings generated by Amazon GuardDuty. Detective then uses machine learning, statistical analysis, and graph theory to generate visualizations that help you conduct effective security investigations more quickly.

These visualizations provide a unified, interactive view of resource behaviors and the interactions between them over time. You can explore this behavior graph to examine potentially malicious actions, such as failed login attempts or suspicious API calls. You can also see how these actions affect resources, such as S3 buckets and objects.

For more information, see the [Amazon Detective Administration Guide](#).

IAM Access Analyzer

AWS Identity and Access Management Access Analyzer (IAM Access Analyzer) can help you identify resources that are shared with an external entity. You can also use IAM Access Analyzer to validate IAM policies against policy grammar and best practices, and generate IAM policies based on access activity in your AWS CloudTrail logs.

IAM Access Analyzer uses logic-based reasoning to analyze resource policies in your AWS environment, such as bucket policies. With IAM Access Analyzer for S3, you're alerted when an S3 bucket is configured to allow access to anyone on the internet or other AWS accounts, including accounts outside your organization. For example, IAM Access Analyzer for S3 can report that a bucket has read or write access provided through a bucket access control list (ACL), a bucket policy, a Multi-Region Access Point policy, or an access point policy. For each public or shared bucket, you receive findings that indicate the source and level of public or shared access. With these findings, you can take immediate and precise corrective action to restore bucket access to what you intended.

For more information, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

Amazon Macie

Amazon Macie is a data security service that discovers sensitive data by using machine learning and pattern matching, provides visibility into data security risks, and enables automated protection against those risks.

With Macie, you can automate discovery and reporting of sensitive data in your S3 buckets to gain a better understanding of the data that your organization stores in Amazon S3. To detect sensitive data, you can use built-in criteria and techniques that Macie provides, custom criteria that you define, or a combination of the two. If Macie detects sensitive data in an S3 object, Macie generates a finding to notify you. This finding provides information about the affected bucket and object, the types and number of occurrences of the sensitive data that Macie found, and additional details to facilitate your investigation.

Macie also provides statistics and other data that offer insight into the security posture of your Amazon S3 data, and it automatically evaluates and monitors your S3 buckets for security and access control. If Macie detects a potential issue with the security or privacy of your data, such as a bucket that becomes publicly accessible, Macie generates a finding for you to review and remediate as necessary.

For more information, see the [Amazon Macie User Guide](#).

AWS Security Hub

AWS Security Hub is a security-posture management service that performs security best-practice checks, aggregates alerts and findings from multiple sources into a single format, and enables automated remediation.

Security Hub collects and provides security findings data from integrated AWS Partner Network security solutions and AWS services, including Amazon Detective, Amazon GuardDuty, IAM Access Analyzer, and Amazon Macie. It also generates its own findings by running continuous, automated security checks based on AWS best practices and supported industry standards.

Security Hub then correlates and consolidates findings across providers to help you prioritize and process the most significant findings. It also provides support for custom actions, which you can use to invoke responses or remediation actions for specific classes of findings.

With Security Hub, you can assess the security and compliance status of your Amazon S3 resources, and you can do so as part of a broader analysis of your organization's security

posture in individual AWS Regions and across multiple Regions. This includes analyzing security trends and identifying the highest-priority security issues. You can also aggregate findings from multiple AWS Regions, and monitor and process aggregated findings data from a single Region.

For more information, see [Amazon Simple Storage Service controls](#) in the *AWS Security Hub User Guide*.

Managing your Amazon S3 storage

After you create buckets and upload objects in Amazon S3, you can manage your object storage using features such as versioning, storage classes, object locking, batch operations, replication, tags, and more. The following sections provide detailed information about the storage management capabilities and features that are available in Amazon S3.

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [What is S3 Express One Zone?](#) and [Directory buckets](#).

- [Performing large-scale batch operations on Amazon S3 objects](#)

Using versioning in S3 buckets

Versioning in Amazon S3 is a means of keeping multiple variants of an object in the same bucket. You can use the S3 Versioning feature to preserve, retrieve, and restore every version of every

object stored in your buckets. With versioning you can recover more easily from both unintended user actions and application failures. After versioning is enabled for a bucket, if Amazon S3 receives multiple write requests for the same object simultaneously, it stores all of those objects.

Versioning-enabled buckets can help you recover objects from accidental deletion or overwrite. For example, if you delete an object, Amazon S3 inserts a delete marker instead of removing the object permanently. The delete marker becomes the current object version. If you overwrite an object, it results in a new object version in the bucket. You can always restore the previous version. For more information, see [Deleting object versions from a versioning-enabled bucket](#).

By default, S3 Versioning is disabled on buckets, and you must explicitly enable it. For more information, see [Enabling versioning on buckets](#).

Note

- The SOAP API does not support S3 Versioning. SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features are not supported for SOAP.
- Normal Amazon S3 rates apply for every version of an object stored and transferred. Each version of an object is the entire object; it is not just a diff from the previous version. Thus, if you have three versions of an object stored, you are charged for three objects.

Unversioned, versioning-enabled, and versioning-suspended buckets

Buckets can be in one of three states:

- Unversioned (the default)
- Versioning-enabled
- Versioning-suspended

You enable and suspend versioning at the bucket level. After you version-enable a bucket, it can never return to an unversioned state. But you can *suspend* versioning on that bucket.

The versioning state applies to all (never some) of the objects in that bucket. When you enable versioning in a bucket, all new objects are versioned and given a unique version ID. Objects that already existed in the bucket at the time versioning was enabled will thereafter *always* be

versioned and given a unique version ID when they are modified by future requests. Note the following:

- Objects that are stored in your bucket before you set the versioning state have a version ID of null. When you enable versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles the objects in future requests. For more information, see [Working with objects in a versioning-enabled bucket](#).
- The bucket owner (or any user with appropriate permissions) can suspend versioning to stop accruing object versions. When you suspend versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles objects in future requests. For more information, see [Working with objects in a versioning-suspended bucket](#).

Using S3 Versioning with S3 Lifecycle

To customize your data retention approach and control storage costs, use object versioning with S3 Lifecycle. For more information, see [Managing your storage lifecycle](#). For information about creating S3 Lifecycle configurations using the AWS Management Console, AWS CLI, AWS SDKs, or the REST API, see [Setting lifecycle configuration on a bucket](#).

Important

If you have an object expiration lifecycle configuration in your unversioned bucket and you want to maintain the same permanent delete behavior when you enable versioning, you must add a noncurrent expiration configuration. The noncurrent expiration lifecycle configuration manages the deletes of the noncurrent object versions in the version-enabled bucket. (A version-enabled bucket maintains one current, and zero or more noncurrent, object versions.) For more information, see [Setting lifecycle configuration on a bucket](#).

For information about working with S3 Versioning, see the following topics.

Topics

- [How S3 Versioning works](#)
- [Enabling versioning on buckets](#)
- [Configuring MFA delete](#)
- [Working with objects in a versioning-enabled bucket](#)

- [Working with objects in a versioning-suspended bucket](#)

How S3 Versioning works

You can use S3 Versioning to keep multiple versions of an object in one bucket so that you can restore objects that are accidentally deleted or overwritten. For example, if you apply S3 Versioning to a bucket, the following changes occur:

- If you delete an object, instead of removing the object permanently, Amazon S3 inserts a delete marker, which becomes the current object version. You can then restore the previous version. For more information, see [Deleting object versions from a versioning-enabled bucket](#).
- If you overwrite an object, Amazon S3 adds a new object version in the bucket. The previous version remains in the bucket and becomes a noncurrent version. You can restore the previous version.

 **Note**

Normal Amazon S3 rates apply for every version of an object that is stored and transferred. Each version of an object is the entire object; it is not a diff from the previous version. Thus, if you have three versions of an object stored, you are charged for three objects.

Each S3 bucket that you create has a *versioning* subresource associated with it. (For more information, see [Bucket configuration options](#).) By default, your bucket is *unversioned*, and the versioning subresource stores the empty versioning configuration, as follows.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</VersioningConfiguration>
```

To enable versioning, you can send a request to Amazon S3 with a versioning configuration that includes an Enabled status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<Status>Enabled</Status>
</VersioningConfiguration>
```

To suspend versioning, you set the status value to Suspended.

Note

When you enable versioning on a bucket for the first time, it might take a short amount of time for the change to be fully propagated. We recommend that you wait for 15 minutes after enabling versioning before issuing write operations (PUT or DELETE) on objects in the bucket.

The bucket owner and all authorized AWS Identity and Access Management (IAM) users can enable versioning. The bucket owner is the AWS account that created the bucket (the root account). For more information about permissions, see [Identity and access management in Amazon S3](#).

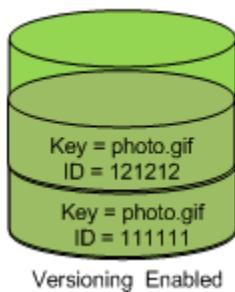

For more information about enabling and disabling S3 Versioning by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or REST API, see [the section called “Enabling versioning on buckets”](#).

Topics

- [Version IDs](#)
- [Versioning workflows](#)

Version IDs

If you enable versioning for a bucket, Amazon S3 automatically generates a unique version ID for the object that is being stored. For example, in one bucket you can have two objects with the same key (object name) but different version IDs, such as photo.gif (version 111111) and photo.gif (version 121212).

Each object has a version ID, whether or not S3 Versioning is enabled. If S3 Versioning is not enabled, Amazon S3 sets the value of the version ID to null. If you enable S3 Versioning, Amazon S3 assigns a version ID value for the object. This value distinguishes that object from other versions of the same key.

When you enable S3 Versioning on an existing bucket, objects that are already stored in the bucket are unchanged. Their version IDs (null), contents, and permissions remain the same. After you enable S3 Versioning, each object that is added to the bucket gets a version ID, which distinguishes it from other versions of the same key.

Only Amazon S3 generates version IDs, and they cannot be edited. Version IDs are Unicode, UTF-8 encoded, URL-ready, opaque strings that are no more than 1,024 bytes long. The following is an example:

3sL4kqtJ1cpXroDTDmJ+rmSpXd3dIbrHY+MTRCx f3v jVBH40Nr8X8gdRQBpUMLUo

 **Note**

For simplicity, the other examples in this topic use much shorter IDs.

Versioning workflows

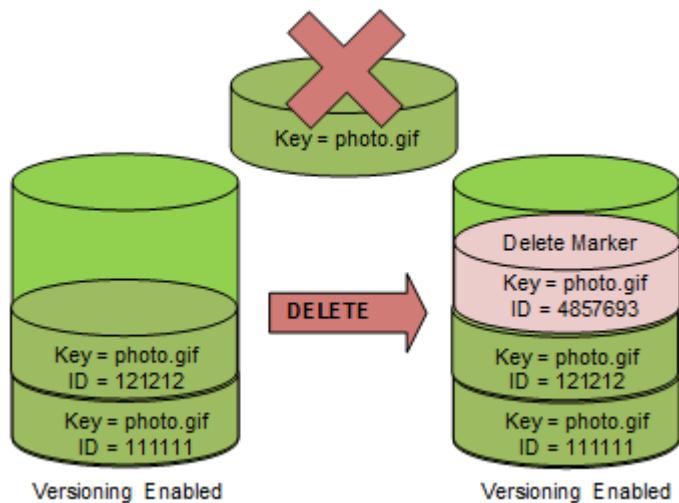

When you PUT an object in a versioning-enabled bucket, the noncurrent version is not overwritten. As shown in the following figure, when a new version of photo.gif is PUT into a bucket that already contains an object with the same name, the following behavior occurs:

- The original object (ID = 111111) remains in the bucket.
- Amazon S3 generates a new version ID (121212), and adds this newer version of the object to the bucket.

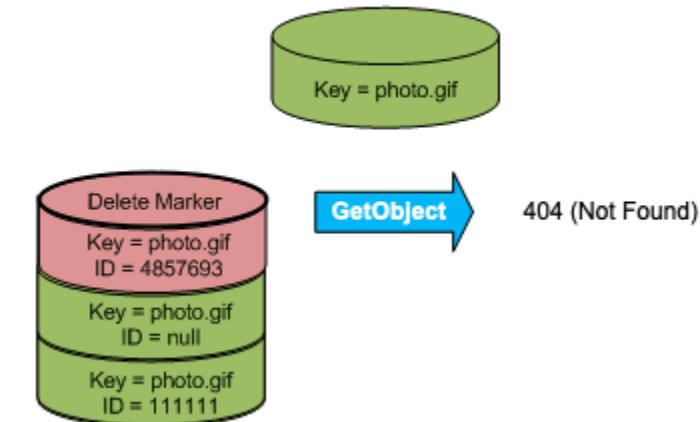

With this functionality, you can retrieve a previous version of an object if an object has been accidentally overwritten or deleted.

When you **DELETE** an object, all versions remain in the bucket, and Amazon S3 inserts a delete marker, as shown in the following figure.

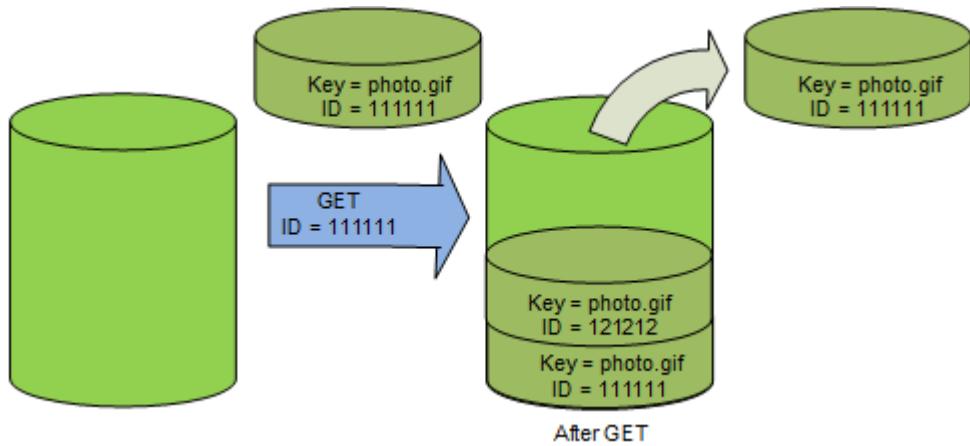

The delete marker becomes the current version of the object. By default, GET requests retrieve the most recently stored version. Performing a `GetObject` request when the current version is a delete marker returns a `404 Not Found` error, as shown in the following figure.

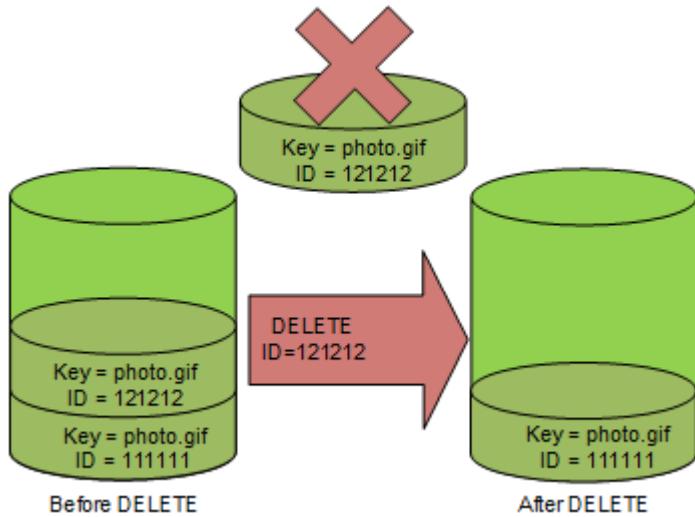

However, you can GET a noncurrent version of an object by specifying its version ID. In the following figure, you GET a specific object version, 111111. Amazon S3 returns that object version even though it's not the current version.

For more information, see [Retrieving object versions from a versioning-enabled bucket](#).

You can permanently delete an object by specifying the version that you want to delete. Only the owner of an Amazon S3 bucket can permanently delete a version. If your DELETE operation specifies the `versionId`, that object version is permanently deleted, and Amazon S3 doesn't insert a delete marker.

You can add more security by configuring a bucket to enable multi-factor authentication (MFA) delete. When you enable MFA delete for a bucket, the bucket owner must include two forms of authentication in any request to delete a version or change the versioning state of the bucket. For more information, see [Configuring MFA delete](#).

When are new versions created for an object?

New versions of objects are created only when you PUT a new object. Be aware that certain actions, such as `CopyObject`, work by implementing a PUT operation.

Some actions that modify the current object don't create a new version because they don't PUT a new object. This includes actions such as changing the tags on an object.

Important

If you notice a significant increase in the number of HTTP 503 (Service Unavailable) responses received for Amazon S3 PUT or DELETE object requests to a bucket that has S3 Versioning enabled, you might have one or more objects in the bucket for which there are millions of versions. For more information, see the S3 Versioning section of [Troubleshooting](#).

Enabling versioning on buckets

You can use S3 Versioning to keep multiple versions of an object in one bucket. This section provides examples of how to enable versioning on a bucket using the console, REST API, AWS SDKs, and AWS Command Line Interface (AWS CLI).

Note

If you enable versioning on a bucket for the first time, it might take up to 15 minutes for the change to be fully propagated. We recommend that you wait for 15 minutes after enabling versioning before issuing write operations (PUT or DELETE) on objects in the bucket. Write operations issued before this conversion is complete may apply to unversioned objects.

For more information about S3 Versioning, see [Using versioning in S3 buckets](#). For information about working with objects that are in versioning-enabled buckets, see [Working with objects in a versioning-enabled bucket](#).

To learn more about how to use S3 Versioning to protect data, see [Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication](#).

Each S3 bucket that you create has a *versioning* subresource associated with it. (For more information, see [Bucket configuration options](#).) By default, your bucket is *unversioned*, and the versioning subresource stores the empty versioning configuration, as follows.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</VersioningConfiguration>
```

To enable versioning, you can send a request to Amazon S3 with a versioning configuration that includes a status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>Enabled</Status>
</VersioningConfiguration>
```

To suspend versioning, you set the status value to Suspended.

The bucket owner and all authorized users can enable versioning. The bucket owner is the AWS account that created the bucket (the root account). For more information about permissions, see [Identity and access management in Amazon S3](#).

The following sections provide more detail about enabling S3 Versioning using the console, AWS CLI, and the AWS SDKs.

Using the S3 console

Follow these steps to use the AWS Management Console to enable versioning on an S3 bucket.

To enable or disable versioning on an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to enable versioning for.
3. Choose **Properties**.
4. Under **Bucket Versioning**, choose **Edit**.
5. Choose **Suspend** or **Enable**, and then choose **Save changes**.

Note

You can use AWS multi-factor authentication (MFA) with versioning. When you use MFA with versioning, you must provide your AWS account's access keys and a valid code from the account's MFA device to permanently delete an object version or suspend or reactivate versioning.

To use MFA with versioning, you enable MFA Delete. However, you can't enable MFA Delete using the AWS Management Console. You must use the AWS Command Line Interface (AWS CLI) or the API. For more information, see [Configuring MFA delete](#).

Using the AWS CLI

The following example enables versioning on an S3 bucket.

```
aws s3api put-bucket-versioning --bucket DOC-EXAMPLE-BUCKET1 --versioning-configuration Status=Enabled
```

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket.

```
aws s3api put-bucket-versioning --bucket DOC-EXAMPLE-BUCKET1 --versioning-configuration Status=Enabled,MFADelete=Enabled --mfa "SERIAL 123456"
```

Note

Using MFA delete requires an approved physical or virtual authentication device. For more information about using MFA delete in Amazon S3, see [Configuring MFA delete](#).

For more information about enabling versioning using the AWS CLI, see [put-bucket-versioning](#) in the *AWS CLI Command Reference*.

Using the AWS SDKs

The following examples enable versioning on a bucket and then retrieve versioning status using the AWS SDK for Java and the AWS SDK for .NET. For information about using other AWS SDKs, see the [AWS Developer Center](#).

.NET

For information about how to create and test a working sample, see [Running the Amazon S3 .NET Code Examples](#).

```
using System;
using Amazon.S3;
using Amazon.S3.Model;

namespace s3.amazonaws.com.docsamples
{
    class BucketVersioningConfiguration
    {
        static string bucketName = "*** bucket name ***";

        public static void Main(string[] args)
        {
            using (var client = new AmazonS3Client(Amazon.RegionEndpoint.USEast1))
            {
                try
                {
                    EnableVersioningOnBucket(client);
                    string bucketVersioningStatus =
                    RetrieveBucketVersioningConfiguration(client);
                }
                catch (AmazonS3Exception amazonS3Exception)
                {
                    if (amazonS3Exception.ErrorCode != null &&
                        (amazonS3Exception.ErrorCode.Equals("InvalidAccessKeyId") ||
                        amazonS3Exception.ErrorCode.Equals("InvalidSecurity")))
                    {
                        Console.WriteLine("Check the provided AWS Credentials.");
                        Console.WriteLine(
                            "To sign up for service, go to http://aws.amazon.com/s3");
                    }
                    else
                    {
                        Console.WriteLine(
                            "Error occurred. Message:{0}' when listing objects",
                            amazonS3Exception.Message);
                    }
                }
            }
        }
    }
}
```

```
        Console.WriteLine("Press any key to continue...");  
        Console.ReadKey();  
    }  
  
    static void EnableVersioningOnBucket(IAmazonS3 client)  
{  
  
        PutBucketVersioningRequest request = new PutBucketVersioningRequest  
        {  
            BucketName = bucketName,  
            VersioningConfig = new S3BucketVersioningConfig  
            {  
                Status = VersionStatus.Enabled  
            }  
        };  
  
        PutBucketVersioningResponse response =  
client.PutBucketVersioning(request);  
    }  
  
    static string RetrieveBucketVersioningConfiguration(IAmazonS3 client)  
{  
        GetBucketVersioningRequest request = new GetBucketVersioningRequest  
        {  
            BucketName = bucketName  
        };  
  
        GetBucketVersioningResponse response =  
client.GetBucketVersioning(request);  
        return response.VersioningConfig.Status;  
    }  
}
```

Java

For instructions on how to create and test a working sample, see [Testing the Amazon S3 Java Code Examples](#).

```
import java.io.IOException;
```

```
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Region;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3Client;
import com.amazonaws.services.s3.model.AmazonS3Exception;
import com.amazonaws.services.s3.model.BucketVersioningConfiguration;
import com.amazonaws.services.s3.model.SetBucketVersioningConfigurationRequest;

public class BucketVersioningConfigurationExample {
    public static String bucketName = "*** bucket name ***";
    public static AmazonS3Client s3Client;

    public static void main(String[] args) throws IOException {
        s3Client = new AmazonS3Client(new ProfileCredentialsProvider());
        s3Client.setRegion(Region.getRegion(Regions.US_EAST_1));
        try {

            // 1. Enable versioning on the bucket.
            BucketVersioningConfiguration configuration =
                new BucketVersioningConfiguration().withStatus("Enabled");

            SetBucketVersioningConfigurationRequest setBucketVersioningConfigurationRequest
            =
                new SetBucketVersioningConfigurationRequest(bucketName, configuration);

            s3Client.setBucketVersioningConfiguration(setBucketVersioningConfigurationRequest);

            // 2. Get bucket versioning configuration information.
            BucketVersioningConfiguration conf =
                s3Client.getBucketVersioningConfiguration(bucketName);
            System.out.println("bucket versioning configuration status: " +
                conf.getStatus());

        } catch (AmazonS3Exception amazonS3Exception) {
            System.out.format("An Amazon S3 error occurred. Exception: %s",
                amazonS3Exception.toString());
        } catch (Exception ex) {
            System.out.format("Exception: %s", ex.toString());
        }
    }
}
```

Python

For instructions on how to create and test a working sample, see [Using the AWS SDK for Python \(Boto\)](#).

The following Python code example creates an Amazon S3 bucket, enables it for versioning, and configures a lifecycle that expires noncurrent object versions after 7 days.

```
def create_versioned_bucket(bucket_name, prefix):
    """
    Creates an Amazon S3 bucket, enables it for versioning, and configures a
    lifecycle
    that expires noncurrent object versions after 7 days.

    Adding a lifecycle configuration to a versioned bucket is a best practice.
    It helps prevent objects in the bucket from accumulating a large number of
    noncurrent versions, which can slow down request performance.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

    :param bucket_name: The name of the bucket to create.
    :param prefix: Identifies which objects are automatically expired under the
                   configured lifecycle rules.
    :return: The newly created bucket.
    """
    try:
        bucket = s3.create_bucket(
            Bucket=bucket_name,
            CreateBucketConfiguration={
                "LocationConstraint": s3.meta.client.meta.region_name
            },
        )
        logger.info("Created bucket %s.", bucket.name)
    except ClientError as error:
        if error.response["Error"]["Code"] == "BucketAlreadyOwnedByYou":
            logger.warning("Bucket %s already exists! Using it.", bucket_name)
            bucket = s3.Bucket(bucket_name)
        else:
            logger.exception("Couldn't create bucket %s.", bucket_name)
            raise

    try:
```

```
        bucket.Versioning().enable()
        logger.info("Enabled versioning on bucket %s.", bucket.name)
    except ClientError:
        logger.exception("Couldn't enable versioning on bucket %s.", bucket.name)
        raise

    try:
        expiration = 7
        bucket.LifecycleConfiguration().put(
            LifecycleConfiguration={
                "Rules": [
                    {
                        "Status": "Enabled",
                        "Prefix": prefix,
                        "NoncurrentVersionExpiration": {"NoncurrentDays": expiration},
                    }
                ]
            }
        )
        logger.info(
            "Configured lifecycle to expire noncurrent versions after %s days "
            "on bucket %s.",
            expiration,
            bucket.name,
        )
    except ClientError as error:
        logger.warning(
            "Couldn't configure lifecycle on bucket %s because %s. "
            "Continuing anyway.",
            bucket.name,
            error,
        )

    return bucket
```

Configuring MFA delete

When working with S3 Versioning in Amazon S3 buckets, you can optionally add another layer of security by configuring a bucket to enable *MFA (multi-factor authentication) delete*. When you do

this, the bucket owner must include two forms of authentication in any request to delete a version or change the versioning state of the bucket.

MFA delete requires additional authentication for either of the following operations:

- Changing the versioning state of your bucket
- Permanently deleting an object version

MFA delete requires two forms of authentication together:

- Your security credentials
- The concatenation of a valid serial number, a space, and the six-digit code displayed on an approved authentication device

MFA delete thus provides added security if, for example, your security credentials are compromised. MFA delete can help prevent accidental bucket deletions by requiring the user who initiates the delete action to prove physical possession of an MFA device with an MFA code and adding an extra layer of friction and security to the delete action.

To identify buckets that have MFA delete enabled, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Assessing your storage activity and usage with S3 Storage Lens](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

The bucket owner, the AWS account that created the bucket (root account), and all authorized users can enable versioning. However, only the bucket owner (root account) can enable MFA delete. For more information, see [Securing Access to AWS Using MFA](#) on the AWS Security Blog.

Note

To use MFA delete with versioning, you enable MFA Delete. However, you cannot enable MFA Delete using the AWS Management Console. You must use the AWS Command Line Interface (AWS CLI) or the API.

For examples of using MFA delete with versioning, see the examples section in the topic [Enabling versioning on buckets](#).

You cannot use MFA delete with lifecycle configurations. For more information about lifecycle configurations and how they interact with other configurations, see [Lifecycle and other bucket configurations](#).

To enable or disable MFA delete, you use the same API that you use to configure versioning on a bucket. Amazon S3 stores the MFA delete configuration in the same *versioning* subresource that stores the bucket's versioning status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>VersioningState</Status>
  <MfaDelete>MfaDeleteState</MfaDelete>
</VersioningConfiguration>
```

To use MFA delete, you can use either a hardware or virtual MFA device to generate an authentication code. The following example shows a generated authentication code displayed on a hardware device.

MFA delete and MFA-protected API access are features intended to provide protection for different scenarios. You configure MFA delete on a bucket to help ensure that the data in your bucket cannot be accidentally deleted. MFA-protected API access is used to enforce another authentication factor (MFA code) when accessing sensitive Amazon S3 resources. You can require any operations against these Amazon S3 resources to be done with temporary credentials created using MFA. For an example, see [Requiring MFA](#).

For more information about how to purchase and activate an authentication device, see [Multi-factor authentication](#).

To enable S3 Versioning and configure MFA delete

Using the AWS CLI

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket.

```
aws s3api put-bucket-versioning --bucket DOC-EXAMPLE-BUCKET1 --versioning-configuration  
Status=Enabled,MFADelete=Enabled --mfa "SERIAL 123456"
```

Using the REST API

For more information about specifying MFA delete using the Amazon S3 REST API, see [PutBucketVersioning](#) *Amazon Simple Storage Service API Reference*.

Working with objects in a versioning-enabled bucket

Objects that are stored in an Amazon S3 bucket before you set the versioning state have a version ID of null. When you enable versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles the objects in future requests.

Transitioning object versions

You can define lifecycle configuration rules for objects that have a well-defined lifecycle to transition object versions to the S3 Glacier Flexible Retrieval storage class at a specific time in the object's lifetime. For more information, see [Managing your storage lifecycle](#).

The topics in this section explain various object operations in a versioning-enabled bucket. For more information about versioning, see [Using versioning in S3 buckets](#).

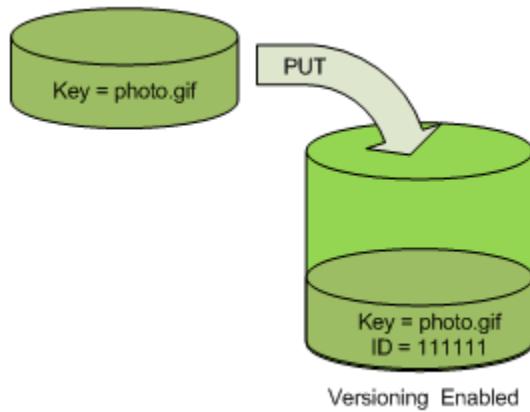

Topics

- [Adding objects to versioning-enabled buckets](#)
- [Listing objects in a versioning-enabled bucket](#)
- [Retrieving object versions from a versioning-enabled bucket](#)
- [Deleting object versions from a versioning-enabled bucket](#)
- [Configuring versioned object permissions](#)

Adding objects to versioning-enabled buckets

After you enable versioning on a bucket, Amazon S3 automatically adds a unique version ID to every object stored (using PUT, POST, or CopyObject) in the bucket.

The following figure shows that Amazon S3 adds a unique version ID to an object when it is added to a versioning-enabled bucket.

Note

The version ID values that Amazon S3 assigns are URL safe (can be included as part of a URI).

For more information about versioning, see [Using versioning in S3 buckets](#). You can add object versions to a versioning-enabled bucket using the console, AWS SDKs, and REST API.

Using the console

For instructions, see [Uploading objects](#).

Using the AWS SDKs

For examples of uploading objects using the AWS SDKs for Java, .NET, and PHP, see [Uploading objects](#). The examples for uploading objects in nonversioned and versioning-enabled buckets are the same, although in the case of versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Using the REST API

To add objects to versioning-enabled buckets

1. Enable versioning on a bucket using a PutBucketVersioning request.

For more information, see [PutBucketVersioning](#) in the *Amazon Simple Storage Service API Reference*.

- Send a PUT, POST, or CopyObject request to store an object in the bucket.

When you add an object to a versioning-enabled bucket, Amazon S3 returns the version ID of the object in the `x-amz-version-id` response header, as shown in the following example.

```
x-amz-version-id: 3/L4kqtJlcpXroDTDmJ+rmSpXd3dIbrHY
```

Listing objects in a versioning-enabled bucket

This section provides examples of listing object versions from a versioning-enabled bucket. Amazon S3 stores object version information in the `versions` subresource that is associated with the bucket. For more information, see [Bucket configuration options](#). In order to list the objects in a versioning-enabled bucket, you need the `ListBucketVersions` permission.

Using the S3 console

Follow these steps to use the Amazon S3 console to see the different versions of an object.

To see multiple versions of an object

- Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- In the **Buckets** list, choose the name of the bucket that contains the object.
- To see a list of the versions of the objects in the bucket, choose the **Show versions** switch.

For each object version, the console shows a unique version ID, the date and time the object version was created, and other properties. (Objects stored in your bucket before you set the versioning state have a version ID of **null**.)

To list the objects without the versions, choose the **List versions** switch.

You also can view, download, and delete object versions in the object overview pane on the console. For more information, see [Viewing an object overview in the Amazon S3 console](#).

Note

To access object versions older than 300 versions, you must use the AWS CLI or the object's URL.

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Using versioning in S3 buckets](#).

Using the AWS SDKs

The examples in this section show how to retrieve an object listing from a versioning-enabled bucket. Each request returns up to 1,000 versions, unless you specify a lower number. If the bucket contains more versions than this limit, you send a series of requests to retrieve the list of all versions. This process of returning results in "pages" is called *pagination*.

To show how pagination works, the examples limit each response to two object versions. After retrieving the first page of results, each example checks to determine whether the version list was truncated. If it was, the example continues retrieving pages until all versions have been retrieved.

Note

The following examples also work with a bucket that isn't versioning-enabled, or for objects that don't have individual versions. In those cases, Amazon S3 returns the object listing with a version ID of null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Java

For instructions on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;

import com.amazonaws.services.s3.model.S3VersionSummary;
```

```
import com.amazonaws.services.s3.model.VersionListing;

public class ListKeysVersioningEnabledBucket {

    public static void main(String[] args) {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "**** Bucket name ****";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(clientRegion)
                .build();

            // Retrieve the list of versions. If the bucket contains more versions
            // than the specified maximum number of results, Amazon S3 returns
            // one page of results per request.
            ListVersionsRequest request = new ListVersionsRequest()
                .withBucketName(bucketName)
                .withMaxResults(2);
            VersionListing versionListing = s3Client.listVersions(request);
            int numVersions = 0, numPages = 0;
            while (true) {
                numPages++;
                for (S3VersionSummary objectSummary :
versionListing.getVersionSummaries()) {
                    System.out.printf("Retrieved object %s, version %s\n",
                        objectSummary.getKey(),
                        objectSummary.getVersionId());
                    numVersions++;
                }
                // Check whether there are more pages of versions to retrieve. If
                // there are, retrieve them. Otherwise, exit the loop.
                if (versionListing.isTruncated()) {
                    versionListing =
s3Client.listNextBatchOfVersions(versionListing);
                } else {
                    break;
                }
            }
            System.out.println(numVersions + " object versions retrieved in " +
numPages + " pages");
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
```

```
// it, so it returned an error response.  
e.printStackTrace();  
} catch (SdkClientException e) {  
    // Amazon S3 couldn't be contacted for a response, or the client  
    // couldn't parse the response from Amazon S3.  
    e.printStackTrace();  
}  
}  
}
```

.NET

For information about how to create and test a working sample, see [Running the Amazon S3 .NET Code Examples](#).

```

        private static IAmazonS3 s3Client;  
  
        public static void Main(string[] args)  
        {  
            s3Client = new AmazonS3Client(bucketRegion);  
            GetObjectListWithAllVersionsAsync().Wait();  
        }  
  
        static async Task GetObjectListWithAllVersionsAsync()  
        {  
            try  
            {  
                ListVersionsRequest request = new ListVersionsRequest()
```

```
        {
            BucketName = bucketName,
            // You can optionally specify key name prefix in the request
            // if you want list of object versions of a specific object.

            // For this example we limit response to return list of 2
            versions.
            MaxKeys = 2
        };
        do
        {
            ListVersionsResponse response = await
            s3Client.ListVersionsAsync(request);
            // Process response.
            foreach (S3ObjectVersion entry in response.Versions)
            {
                Console.WriteLine("key = {0} size = {1}",
                    entry.Key, entry.Size);
            }

            // If response is truncated, set the marker to get the next
            // set of keys.
            if (response.IsTruncated)
            {
                request.KeyMarker = response.NextKeyMarker;
                request.VersionIdMarker = response.NextVersionIdMarker;
            }
            else
            {
                request = null;
            }
        } while (request != null);
    }
    catch (AmazonS3Exception e)
    {
        Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
    catch (Exception e)
    {
        Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
}
```

```
}
```

Using the REST API

Example — Listing all object versions in a bucket

To list all the versions of all the objects in a bucket, you use the `versions` subresource in a GET Bucket request. Amazon S3 can retrieve a maximum of 1,000 objects, and each object version counts fully as an object. Therefore, if a bucket contains two keys (for example, `photo.gif` and `picture.jpg`), and the first key has 990 versions and the second key has 400 versions, a single request would retrieve all 990 versions of `photo.gif` and only the most recent 10 versions of `picture.jpg`.

Amazon S3 returns object versions in the order in which they were stored, with the most recently stored returned first.

In a GET Bucket request, include the `versions` subresource.

```
GET /?versions HTTP/1.1
Host: bucketName.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 +0000
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQF4/cRonhpaBX5sCYVf1bNRuU=
```

Example — Retrieving all versions of a key

To retrieve a subset of object versions, you use the request parameters for GET Bucket. For more information, see [GET Bucket](#).

1. Set the `prefix` parameter to the key of the object that you want to retrieve.
2. Send a GET Bucket request using the `versions` subresource and `prefix`.

```
GET /?versions&prefix=objectName HTTP/1.1
```

Example — Retrieving objects using a prefix

The following example retrieves objects whose key is or begins with `myObject`.

```
GET /?versions&prefix=myObject HTTP/1.1
```

```
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

You can use the other request parameters to retrieve a subset of all versions of the object. For more information, see [GET Bucket](#) in the *Amazon Simple Storage Service API Reference*.

Example — Retrieving a listing of additional objects if the response is truncated

If the number of objects that could be returned in a GET request exceeds the value of max-keys, the response contains <isTruncated>true</isTruncated>, and includes the first key (in NextKeyMarker) and the first version ID (in NextVersionIdMarker) that satisfy the request, but were not returned. You use those returned values as the starting position in a subsequent request to retrieve the additional objects that satisfy the GET request.

Use the following process to retrieve additional objects that satisfy the original GET Bucket versions request from a bucket. For more information about key-marker, version-id-marker, NextKeyMarker, and NextVersionIdMarker, see [GET Bucket](#) in the *Amazon Simple Storage Service API Reference*.

The following are additional responses that satisfy the original GET request:

- Set the value of key-marker to the key returned in NextKeyMarker in the previous response.
- Set the value of version-id-marker to the version ID returned in NextVersionIdMarker in the previous response.
- Send a GET Bucket versions request using key-marker and version-id-marker.

Example — Retrieving objects starting with a specified key and version ID

```
GET /?versions&key-marker=myObject&version-id-marker=298459348571 HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

Using the AWS CLI

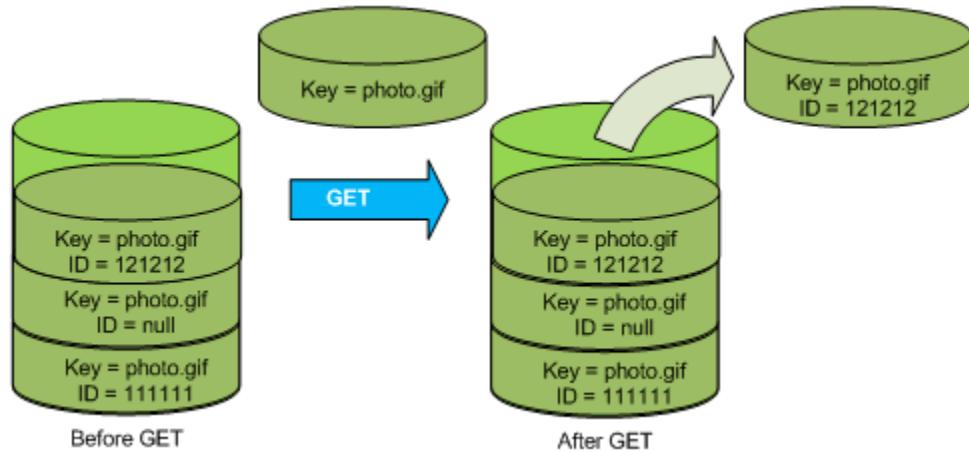

The following command returns metadata about all versions of the objects in a bucket.

```
aws s3api list-object-versions --bucket DOC-EXAMPLE-BUCKET1
```

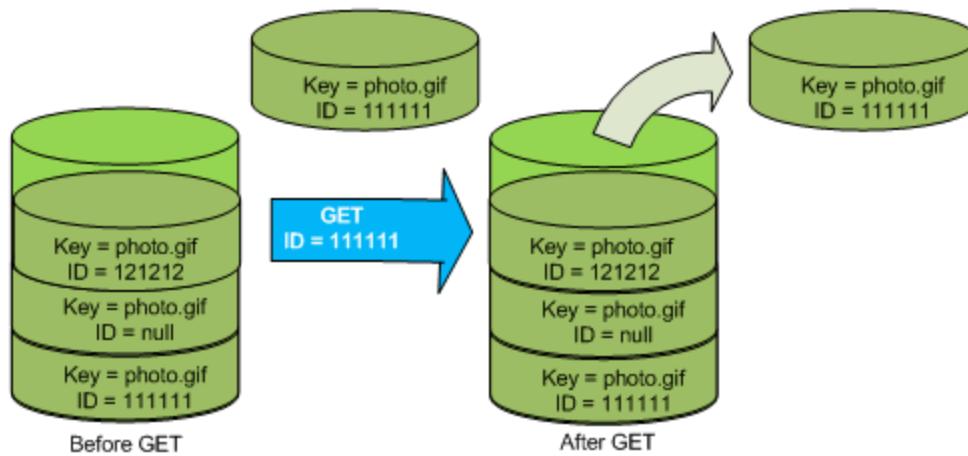

For more information about `list-object-versions` see [list-object-versions in the AWS CLI Command Reference](#).

Retrieving object versions from a versioning-enabled bucket

Versioning in Amazon S3 is a way of keeping multiple variants of an object in the same bucket. A simple GET request retrieves the current version of an object. The following figure shows how GET returns the current version of the object, `photo.gif`.

To retrieve a specific version, you have to specify its version ID. The following figure shows that a `GET versionId` request retrieves the specified version of the object (not necessarily the current one).

You can retrieve object versions in Amazon S3 using the console, AWS SDKs, or REST API.

Note

To access object versions older than 300 versions, you must use the AWS CLI or the object's URL.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to retrieve.
6. Choose **Actions**, choose **Download**, and save the object.

You also can view, download, and delete object versions in the object overview panel. For more information, see [Viewing an object overview in the Amazon S3 console](#).

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Using versioning in S3 buckets](#).

Using the AWS SDKs

The examples for uploading objects in nonversioned and versioning-enabled buckets are the same. However, for versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For examples of downloading objects using AWS SDKs for Java, .NET, and PHP, see [Downloading objects](#).

For examples of listing the version of objects using AWS SDKs for .NET and Rust, see [List the version of objects in an Amazon S3 bucket](#).

Using the REST API

To retrieve a specific object version

1. Set `versionId` to the ID of the version of the object that you want to retrieve.
2. Send a `GET Object versionId` request.

Example — Retrieving a versioned object

The following request retrieves version L4kqtJlcpXroDTDmpUMLUo of `my-image.jpg`.

```
GET /my-image.jpg?versionId=L4kqtJlcpXroDTDmpUMLUo HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

You can retrieve just the metadata of an object (not the content). For information, see [the section called “Retrieving version metadata”](#).

For information about restoring a previous object version, see [the section called “Restoring previous versions”](#).

Retrieving the metadata of an object version

If you only want to retrieve the metadata of an object (and not its content), you use the `HEAD` operation. By default, you get the metadata of the most recent version. To retrieve the metadata of a specific object version, you specify its version ID.

To retrieve the metadata of an object version

1. Set `versionId` to the ID of the version of the object whose metadata you want to retrieve.
2. Send a `HEAD Object versionId` request.

Example — Retrieving the metadata of a versioned object

The following request retrieves the metadata of version 3HL4kqCxf3vjVBH40Nrjfkd of `my-image.jpg`.

```
HEAD /my-image.jpg?versionId=3HL4kqCxf3vjVBH40Nrjfkd HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

The following shows a sample response.

```
HTTP/1.1 200 OK
x-amz-id-2: ef8yU9AS1ed40pIszj7UDNEHGran
x-amz-request-id: 318BC8BC143432E5
x-amz-version-id: 3HL4kqtJlcpXroDTDmjVBH40Nrjfkd
Date: Wed, 28 Oct 2009 22:32:00 GMT
Last-Modified: Sun, 1 Jan 2006 12:00:00 GMT
ETag: "fba9dede5f27731c9771645a39863328"
Content-Length: 434234
Content-Type: text/plain
Connection: close
Server: AmazonS3
```

Restoring previous versions

You can use versioning to retrieve previous versions of an object. There are two approaches to doing so:

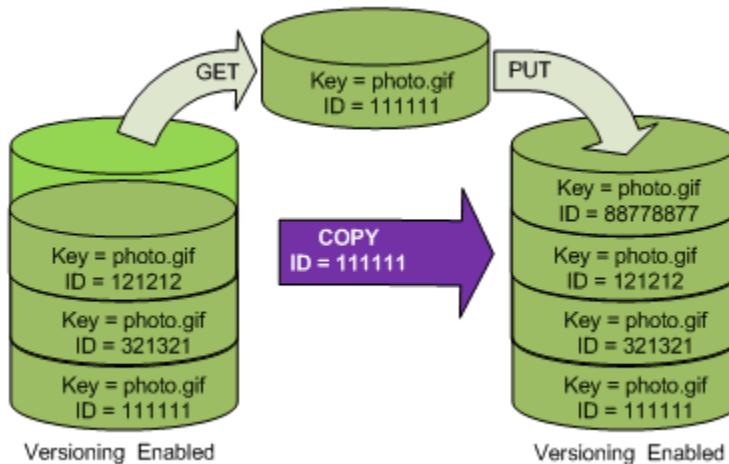

- Copy a previous version of the object into the same bucket.

The copied object becomes the current version of that object and all object versions are preserved.

- Permanently delete the current version of the object.

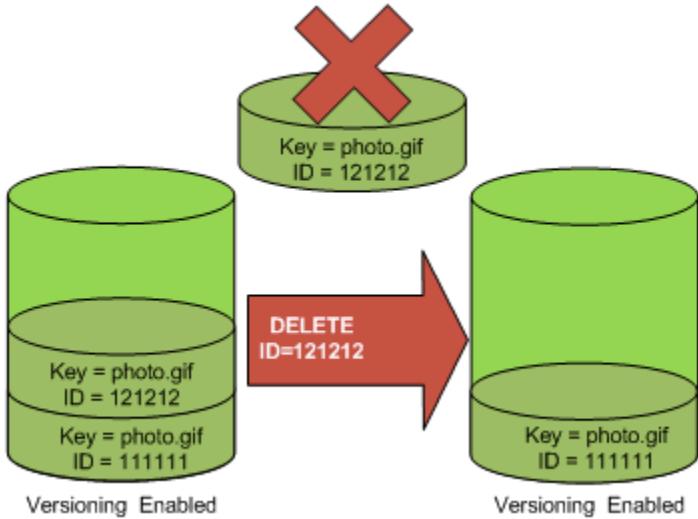

When you delete the current object version, you, in effect, turn the previous version into the current version of that object.

Because all object versions are preserved, you can make any earlier version the current version by copying a specific version of the object into the same bucket. In the following figure, the source object (ID = 111111) is copied into the same bucket. Amazon S3 supplies a new ID (88778877) and it becomes the current version of the object. So, the bucket has both the original object version (111111) and its copy (88778877). For more information about getting a previous version and then uploading it to make it the current version, see [Retrieving object versions from a versioning-enabled bucket](#) and [Uploading objects](#).

A subsequent GET retrieves version 88778877.

The following figure shows how deleting the current version (121212) of an object leaves the previous version (111111) as the current object. For more information about deleting an object, see [Deleting a single object](#).

A subsequent GET retrieves version 111111.

Note

To restore object versions in batches, you can [use the CopyObject operation](#). The CopyObject operation copies each object that is specified in the manifest. However, be aware that objects aren't necessarily copied in the same order as they appear in the manifest. For versioned buckets, if preserving current/non-current version order

is important, you should copy all non-current versions first. Then, after the first job is complete, copy the current versions in a subsequent job.

To restore previous object versions

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to retrieve.
6. Choose **Actions**, choose **Download**, and save the object.

You also can view, download, and delete object versions in the object overview panel. For more information, see [Viewing an object overview in the Amazon S3 console](#).

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Using versioning in S3 buckets](#).

Using the AWS SDKs

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Python

For instructions on how to create and test a working sample, see [Using the AWS SDK for Python \(Boto\)](#).

The following Python code example restores a versioned object's previous version by deleting all versions that occurred after the specified rollback version.

```
def rollback_object(bucket, object_key, version_id):
    """
    Rolls back an object to an earlier version by deleting all versions that
    occurred after the specified rollback version.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

    :param bucket: The bucket that holds the object to roll back.
    :param object_key: The object to roll back.
    :param version_id: The version ID to roll back to.
    """
    # Versions must be sorted by last_modified date because delete markers are
    # at the end of the list even when they are interspersed in time.
    versions = sorted(
        bucket.object_versions.filter(Prefix=object_key),
        key=attrgetter("last_modified"),
        reverse=True,
    )

    logger.debug(
        "Got versions:\n%s",
        "\n".join(
            [
                f"\t{version.version_id}, last modified {version.last_modified}"
                for version in versions
            ]
        ),
    )

    if version_id in [ver.version_id for ver in versions]:
        print(f"Rolling back to version {version_id}")
        for version in versions:
            if version.version_id != version_id:
                version.delete()
                print(f"Deleted version {version.version_id}")
            else:
                break

        print(f"Active version is now {bucket.Object(object_key).version_id}")
    else:
        raise KeyError()
```

```
f"{version_id} was not found in the list of versions for "
f"{object_key}."
)
```

Deleting object versions from a versioning-enabled bucket

You can delete object versions from Amazon S3 buckets whenever you want. You can also define lifecycle configuration rules for objects that have a well-defined lifecycle to request Amazon S3 to expire current object versions or permanently remove noncurrent object versions. When your bucket is version-enabled or versioning is suspended, the lifecycle configuration actions work as follows:

- The `Expiration` action applies to the current object version. Instead of deleting the current object version, Amazon S3 retains the current version as a noncurrent version by adding a *delete marker*, which then becomes the current version.
- The `NoncurrentVersionExpiration` action applies to noncurrent object versions, and Amazon S3 permanently removes these object versions. You cannot recover permanently removed objects.

For more information about S3 Lifecycle, see [Managing your storage lifecycle](#) and [Examples of S3 Lifecycle configuration](#).

To see how many current and noncurrent object versions that your buckets have, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to optimize your storage costs](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

Note

Normal Amazon S3 rates apply for every version of an object that is stored and transferred, including noncurrent object versions. For more information, see [Amazon S3 pricing](#).

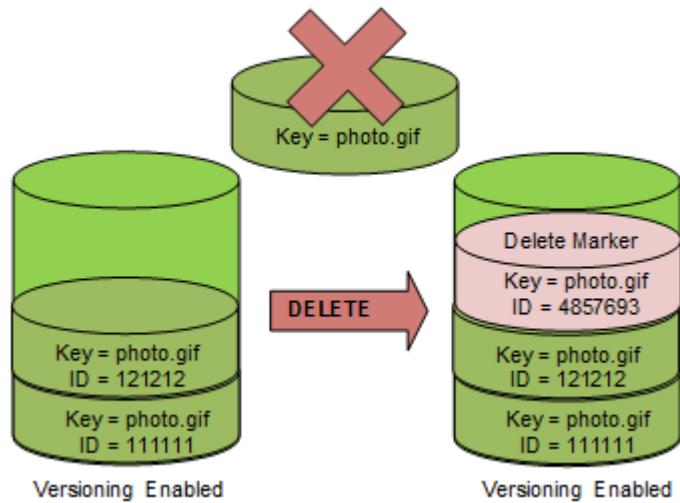

Delete request use cases

A DELETE request has the following use cases:

- When versioning is enabled, a simple DELETE cannot permanently delete an object. (A simple DELETE request is a request that doesn't specify a version ID.) Instead, Amazon S3 inserts a delete marker in the bucket, and that marker becomes the current version of the object with a new ID.

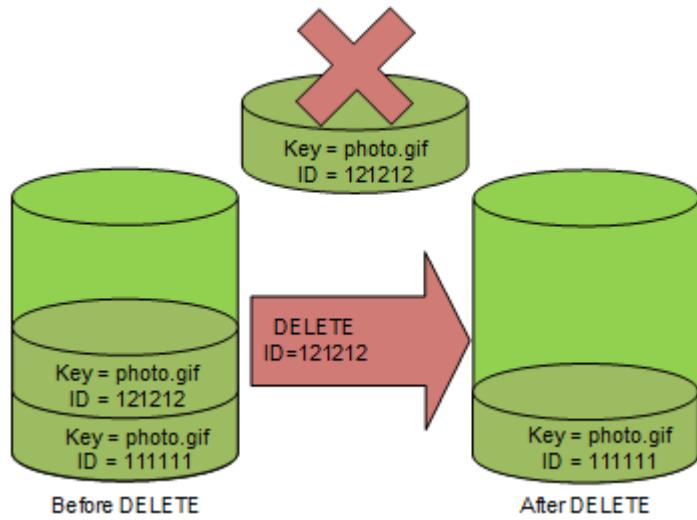

When you try to GET an object whose current version is a delete marker, Amazon S3 behaves as though the object has been deleted (even though it has not been erased) and returns a 404 error. For more information, see [Working with delete markers](#).

The following figure shows that a simple DELETE does not actually remove the specified object. Instead, Amazon S3 inserts a delete marker.

- To delete versioned objects permanently, you must use `DELETE Object versionId`.

The following figure shows that deleting a specified object version permanently removes that object.

To delete object versions

You can delete object versions in Amazon S3 using the console, AWS SDKs, the REST API, or the AWS Command Line Interface.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to permanently delete.
6. Choose **Delete**.
7. In **Permanently delete objects?**, enter **permanently delete**.

⚠ Warning

When you permanently delete an object version, the action cannot be undone.

8. Choose **Delete objects**.

Amazon S3 deletes the object version.

Using the AWS SDKs

For examples of deleting objects using the AWS SDKs for Java, .NET, and PHP, see [Deleting Amazon S3 objects](#). The examples for deleting objects in nonversioned and versioning-enabled buckets are the same. However, for versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Python

For instructions on how to create and test a working sample, see [Using the AWS SDK for Python \(Boto\)](#).

The following Python code example permanently deletes a versioned object by deleting all of its versions.

```
def permanently_delete_object(bucket, object_key):
    """
    Permanently deletes a versioned object by deleting all of its versions.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

    :param bucket: The bucket that contains the object.
    :param object_key: The object to delete.
    """
    try:
        bucket.object_versions.filter(Prefix=object_key).delete()
        logger.info("Permanently deleted all versions of object %s.", object_key)
    except ClientError:
        logger.exception("Couldn't delete all versions of %s.", object_key)
        raise
```

Using the REST API

To delete a specific version of an object

- In a DELETE, specify a version ID.

Example — Deleting a specific version

The following example deletes version UIORUnfd89493jJFJ of photo.gif.

```
DELETE /photo.gif?versionId=UIORUnfd89493jJFJ HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:xQE0diMbLRepdf3YB+FIEXAMPLE=
Content-Type: text/plain
Content-Length: 0
```

Using the AWS CLI

The following command deletes an object named test.txt from a bucket named *DOC-EXAMPLE-BUCKET1*. To remove a specific version of an object, you must be the bucket owner and you must use the version Id subresource.

```
aws s3api delete-object --bucket DOC-EXAMPLE-BUCKET1 --key test.txt --version-id versionID
```

For more information about `delete-object` see [delete-object](#) in the *AWS CLI Command Reference*.

For more information about deleting object versions, see the following topics:

- [Working with delete markers](#)
- [Removing delete markers to make an older version current](#)
- [Deleting an object from an MFA delete-enabled bucket](#)

Working with delete markers

A *delete marker* in Amazon S3 is a placeholder (or marker) for a versioned object that was specified in a simple DELETE request. A simple DELETE request is a request that doesn't specify a version ID. Because the object is in a versioning-enabled bucket, the object is not deleted. But the delete

marker makes Amazon S3 behave as if the object is deleted. You can use an Amazon S3 API DELETE call on a delete marker. To do this, you must make the DELETE request by using an AWS Identity and Access Management (IAM) user or role with the appropriate permissions.

A delete marker has a *key name* (or *key*) and version ID like any other object. However, a delete marker differs from other objects in the following ways:

- A delete marker doesn't have data associated with it.
- A delete marker isn't associated with an access control list (ACL) value.
- If you issue a GET request for a delete marker, the GET request doesn't retrieve anything because a delete marker has no data. Specifically, when your GET request doesn't specify a `versionId`, you get a 404 (Not Found) error.

Delete markers accrue a minimal charge for storage in Amazon S3. The storage size of a delete marker is equal to the size of the key name of the delete marker. A key name is a sequence of Unicode characters. The UTF-8 encoding for the key name adds 1-4 bytes of storage to your bucket for each character in the name. Delete markers are stored in the S3 Standard storage class.

If you want to find out how many delete markers you have and what storage class they're stored in, you can use Amazon S3 Storage Lens. For more information, see [Assessing your storage activity and usage with Amazon S3 Storage Lens](#) and [Amazon S3 Storage Lens metrics glossary](#).

For more information about key names, see [Creating object key names](#). For information about deleting a delete marker, see [Managing delete markers](#).

Only Amazon S3 can create a delete marker, and it does so whenever you send a `DeleteObject` request on an object in a versioning-enabled or suspended bucket. The object specified in the `DELETE` request is not actually deleted. Instead, the delete marker becomes the current version of the object. The object's key name (or key) becomes the key of the delete marker.

When you get an object without specifying a `versionId` in your request, if its current version is a delete marker, Amazon S3 responds with the following:

- A 404 (Not Found) error
- A response header, `x-amz-delete-marker: true`

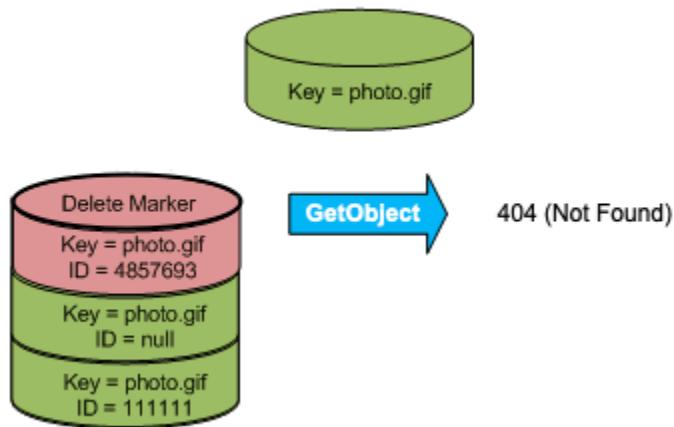

When you get an object by specifying a `versionId` in your request, if the specified version is a delete marker, Amazon S3 responds with the following:

- A 405 (Method Not Allowed) error
- A response header, `x-amz-delete-marker: true`
- A response header, `Last-Modified: timestamp` (only when using the [HeadObject](#) or [GetObject](#) API operations)

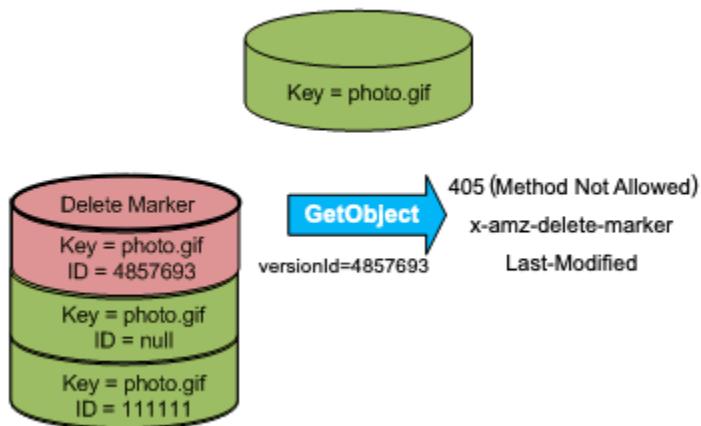

The `x-amz-delete-marker: true` response header tells you that the object accessed was a delete marker. This response header never returns false, because when the value is false, the current or specified version of the object is not a delete marker.

The `Last-Modified` response header provides the creation time of the delete markers.

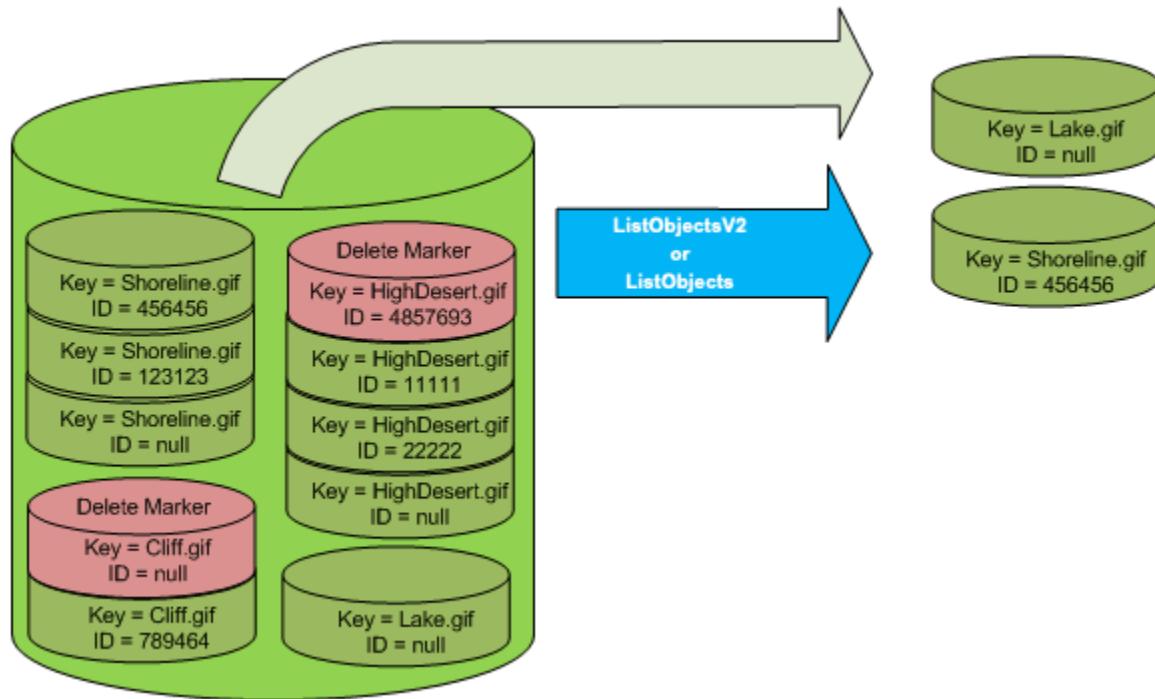

The following figure shows how a `GetObject` API call on an object whose current version is a delete marker responds with a 404 (Not Found) error and the response header includes `x-amz-delete-marker: true`.

If you make a `GetObject` call on an object by specifying a `versionId` in your request, and if the specified version is a delete marker, Amazon S3 responds with a 405 (Method Not Allowed) error and the response headers include `x-amz-delete-marker: true` and `Last-Modified: timestamp`.

The only way to list delete markers (and other versions of an object) is by using the `versions` subresource in a [ListObjectVersions](#) request. The following figure shows that a [ListObjectsV2](#) or [ListObjects](#) request doesn't return objects whose current version is a delete marker.

Managing delete markers

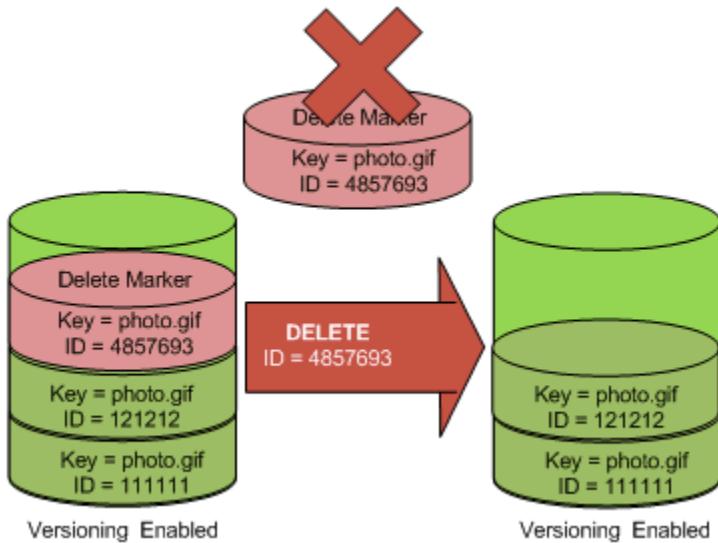

Configuring lifecycle to clean up expired delete markers automatically

An expired object delete marker is one where all object versions are deleted and only a single delete marker remains. If the lifecycle configuration is set to delete current versions, or the `ExpiredObjectDeleteMarker` action is explicitly set, Amazon S3 removes the expired object's delete marker. For an example, see [Example 7: Removing expired object delete markers](#).

Removing delete markers to make an older version current

When you delete an object in a versioning-enabled bucket, all versions remain in the bucket, and Amazon S3 creates a delete marker for the object. To undelete the object, you must delete this delete marker. For more information about versioning and delete markers, see [Using versioning in S3 buckets](#).

To delete a delete marker permanently, you must include its version ID in a `DeleteObject` `versionId` request. The following figure shows how a `DeleteObject` `versionId` request permanently removes a delete marker.

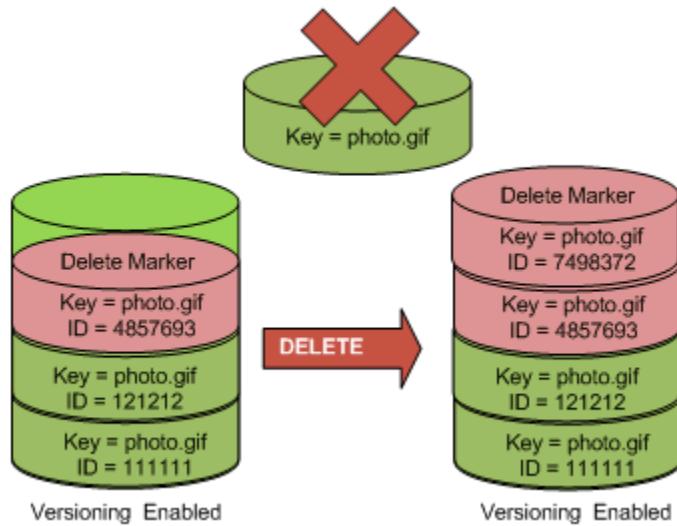

The effect of removing the delete marker is that a simple GET request will now retrieve the current version ID (121212) of the object.

Note

If you use a `DeleteObject` request where the current version is a delete marker (without specifying the version ID of the delete marker), Amazon S3 does not delete the delete marker, but instead PUTs another delete marker.

To delete a delete marker with a NULL version ID, you must pass the NULL as the version ID in the `DeleteObject` request. The following figure shows how a simple `DeleteObject` request made without a version ID where the current version is a delete marker, removes nothing, but instead adds an additional delete marker with a unique version ID (7498372).

Using the S3 console

Use the following steps to recover deleted objects that are not folders from your S3 bucket, including objects that are within those folders.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. To see a list of the **versions** of the objects in the bucket, choose the **List versions** switch. You'll be able to see the delete markers for deleted objects.
4. To undelete an object, you must delete the delete marker. Select the check box next to the **delete marker** of the object to recover, and then choose **Delete**.
5. Confirm the deletion on the **Delete objects** page.
 - a. For **Permanently delete objects?** enter **permanently delete**.
 - b. Choose **Delete objects**.

Note

You can't use the Amazon S3 console to undelete folders. You must use the AWS CLI or SDK. For examples, see [How can I retrieve an Amazon S3 object that was deleted in a versioning-enabled bucket?](#) in the AWS Knowledge Center.

Using the REST API

To permanently remove a delete marker

1. Set `versionId` to the ID of the version to the delete marker you want to remove.
2. Send a `DELETE Object versionId` request.

Example — Removing a delete marker

The following example removes the delete marker for `photo.gif` version 4857693.

```
DELETE /photo.gif?versionId=4857693 HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

When you delete a delete marker, Amazon S3 includes the following in the response.

```
204 NoContent
x-amz-version-id: versionID
x-amz-delete-marker: true
```

Using the AWS SDKs

For information about using other AWS SDKs, see the [AWSDeveloper Center](#).

Python

For instructions on how to create and test a working sample, see [Using the AWS SDK for Python \(Boto\)](#).

The following Python code example demonstrates how to remove a delete marker from an object and thus makes the most recent non-current version, the current version of the object.

```
def revive_object(bucket, object_key):
    """
    Revives a versioned object that was deleted by removing the object's active
    delete marker.
    A versioned object presents as deleted when its latest version is a delete
    marker.
    By removing the delete marker, we make the previous version the latest version
    and the object then presents as *not* deleted.
    """
```

Usage is shown in the `usage_demo_single_object` function at the end of this module.

```
:param bucket: The bucket that contains the object.
:param object_key: The object to revive.
"""

# Get the latest version for the object.
response = s3.meta.client.list_object_versions(
    Bucket=bucket.name, Prefix=object_key, MaxKeys=1
)

if "DeleteMarkers" in response:
    latest_version = response["DeleteMarkers"][0]
    if latest_version["IsLatest"]:
        logger.info(
            "Object %s was indeed deleted on %s. Let's revive it.",
            object_key,
            latest_version["LastModified"],
        )
        obj = bucket.Object(object_key)
        obj.Version(latest_version["VersionId"]).delete()
        logger.info(
            "Revived %s, active version is now %s with body '%s'",
            object_key,
            obj.version_id,
            obj.get()["Body"].read(),
        )
    else:
        logger.warning(
            "Delete marker is not the latest version for %s!", object_key
        )
elif "Versions" in response:
    logger.warning("Got an active version for %s, nothing to do.", object_key)
else:
    logger.error("Couldn't get any version info for %s.", object_key)
```

Deleting an object from an MFA delete-enabled bucket

If a bucket's versioning configuration is MFA delete enabled, the bucket owner must include the `x-amz-mfa` request header in requests to permanently delete an object version or change the versioning state of the bucket. Requests that include `x-amz-mfa` must use HTTPS.

The header's value is the concatenation of your authentication device's serial number, a space, and the authentication code displayed on it. If you don't include this request header, the request fails.

For more information about authentication devices, see [Multi-factor Authentication](#).

Example — Deleting an object from an MFA delete-enabled bucket

The following example deletes `my-image.jpg` (with the specified version), which is in a bucket configured with MFA delete enabled.

Note the space between `[SerialNumber]` and `[AuthenticationCode]`. For more information, see [DeleteObject](#) in the *Amazon Simple Storage Service API Reference*.

```
DELETE /my-image.jpg?versionId=3HL4kqCxf3vjVBH40Nrjfkd HTTPS/1.1
Host: bucketName.s3.amazonaws.com
x-amz-mfa: 20899872 301749
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

For more information about enabling MFA delete, see [Configuring MFA delete](#).

Configuring versioned object permissions

Permissions for objects in Amazon S3 are set at the version level. Each version has its own object owner. The AWS account that creates the object version is the owner. So, you can set different permissions for different versions of the same object. To do so, you must specify the version ID of the object whose permissions you want to set in a `PUT Object versionId acl` request. For a detailed description and instructions on using ACLs, see [Identity and access management in Amazon S3](#).

Example — Setting permissions for an object version

The following request sets the permission of the grantee, `BucketOwner@amazon.com`, to `FULL_CONTROL` on the key, `my-image.jpg`, version ID, `3HL4kqtJvjVBH40Nrjfkd`.

```
PUT /my-image.jpg?acl&versionId=3HL4kqtJvjVBH40Nrjfkd HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
Content-Length: 124

<AccessControlPolicy>
  <Owner>
    <ID>75cc57f09aa0c8caeab4f8c24e99d10f8e7faebf76c078efc7c6caea54ba06a</ID>
    <DisplayName>mtd@amazon.com</DisplayName>
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
        <ID>a9a7b886d6fd24a52fe8ca5bef65f89a64e0193f23000e241bf9b1c61be666e9</ID>
        <DisplayName>BucketOwner@amazon.com</DisplayName>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
  </AccessControlList>
</AccessControlPolicy>
```

Likewise, to get the permissions of a specific object version, you must specify its version ID in a GET Object `versionId acl` request. You need to include the version ID because, by default, GET Object `acl` returns the permissions of the current version of the object.

Example — Retrieving the permissions for a specified object version

In the following example, Amazon S3 returns the permissions for the key, `my-image.jpg`, version ID, `DVBH40Nr8X8gUMLUo`.

```
GET /my-image.jpg?versionId=DVBH40Nr8X8gUMLUo&acl HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU
```

For more information, see [GetObjectAcl](#) in the *Amazon Simple Storage Service API Reference*.

Working with objects in a versioning-suspended bucket

In Amazon S3, you can suspend versioning to stop accruing new versions of the same object in a bucket. You might do this because you only want a single version of an object in a bucket. Or, you might not want to accrue charges for multiple versions.

When you suspend versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles objects in future requests. The topics in this section explain various object operations in a versioning-suspended bucket, including adding, retrieving, and deleting objects.

For more information about S3 Versioning, see [Using versioning in S3 buckets](#). For more information about retrieving object versions, see [Retrieving object versions from a versioning-enabled bucket](#).

Topics

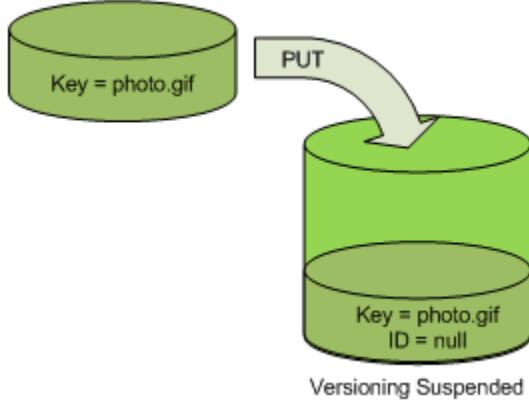

- [Adding objects to versioning-suspended buckets](#)
- [Retrieving objects from versioning-suspended buckets](#)
- [Deleting objects from versioning-suspended buckets](#)

Adding objects to versioning-suspended buckets

You can add objects to versioning-suspended buckets in Amazon S3 to create the object with a null version ID or overwrite any object version with a matching version ID.

After you suspend versioning on a bucket, Amazon S3 automatically adds a null version ID to every subsequent object stored thereafter (using PUT, POST, or CopyObject) in that bucket.

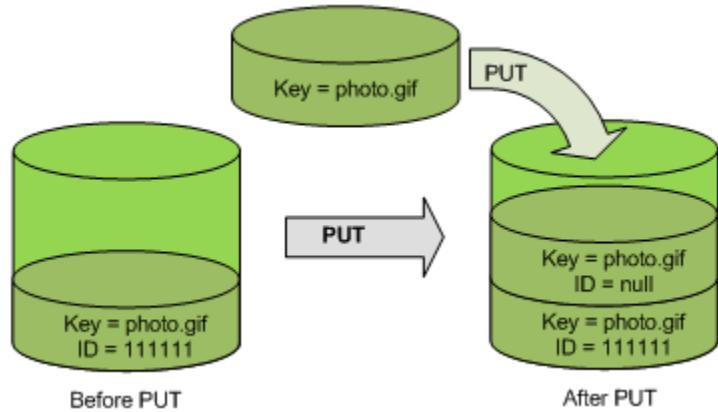

The following figure shows how Amazon S3 adds the version ID of null to an object when it is added to a version-suspended bucket.

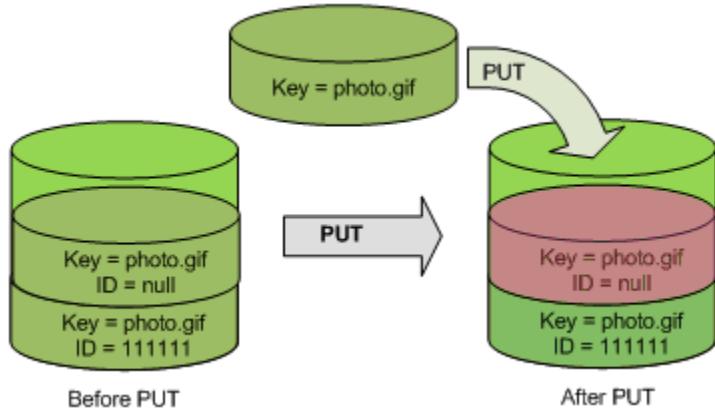

If a null version is already in the bucket and you add another object with the same key, the added object overwrites the original null version.

If there are versioned objects in the bucket, the version you PUT becomes the current version of the object. The following figure shows how adding an object to a bucket that contains versioned objects does not overwrite the object already in the bucket.

In this case, version 111111 was already in the bucket. Amazon S3 attaches a version ID of null to the object being added and stores it in the bucket. Version 111111 is not overwritten.

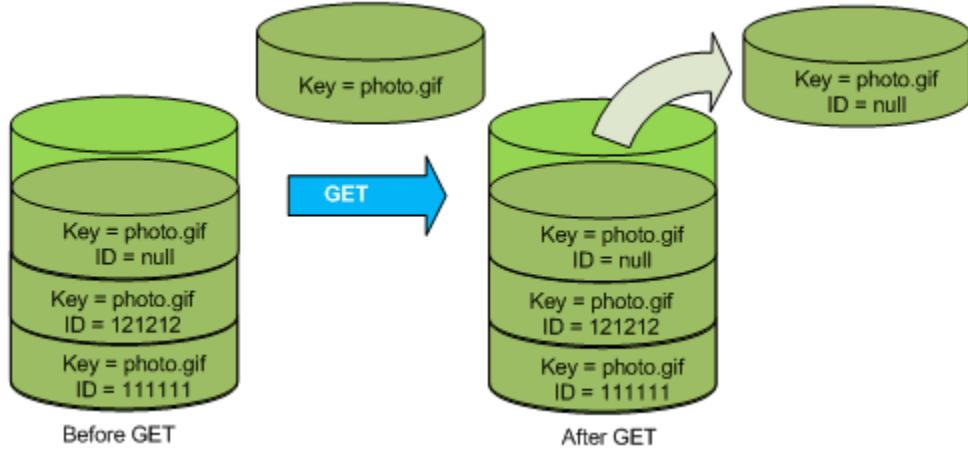

If a null version already exists in a bucket, the null version is overwritten, as shown in the following figure.

Although the key and version ID (null) of the null version are the same before and after the PUT, the contents of the null version originally stored in the bucket are replaced by the contents of the object PUT into the bucket.

Retrieving objects from versioning-suspended buckets

A GET Object request returns the current version of an object whether you've enabled versioning on a bucket or not. The following figure shows how a simple GET returns the current version of an object.

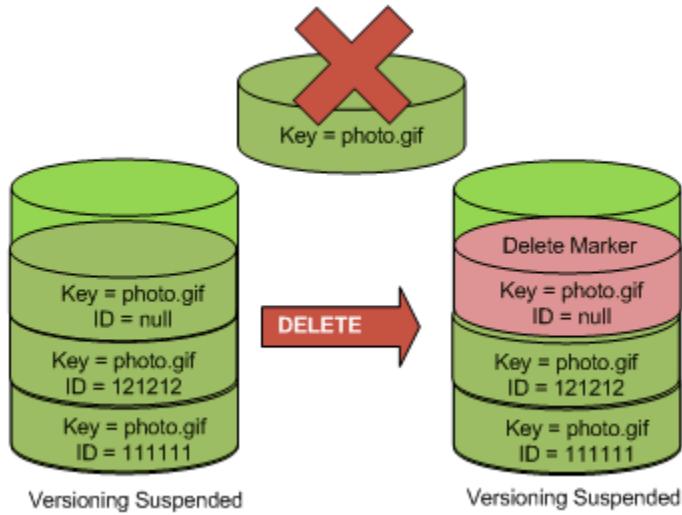

Deleting objects from versioning-suspended buckets

You can delete objects from versioning-suspended buckets to remove an object with a null version ID.

If versioning is suspended for a bucket, a DELETE request:

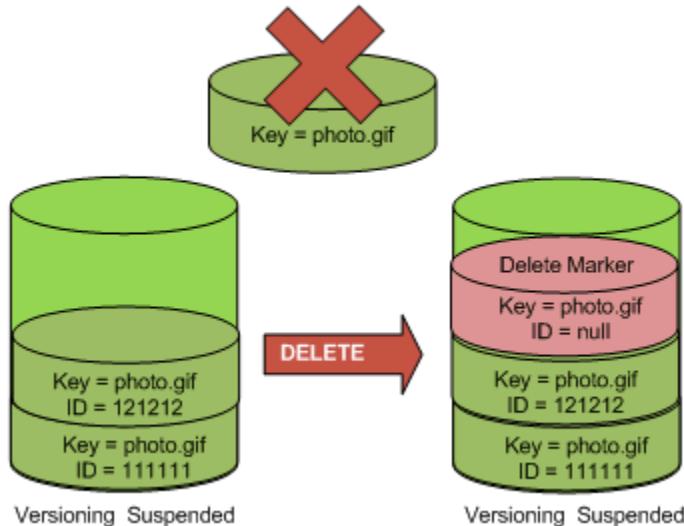

- Can only remove an object whose version ID is null.
- Doesn't remove anything if there isn't a null version of the object in the bucket.
- Inserts a delete marker into the bucket.

The following figure shows how a simple DELETE removes a null version. (A simple DELETE request is a request that doesn't specify a version ID.) Amazon S3 inserts a delete marker in its place with a version ID of null.

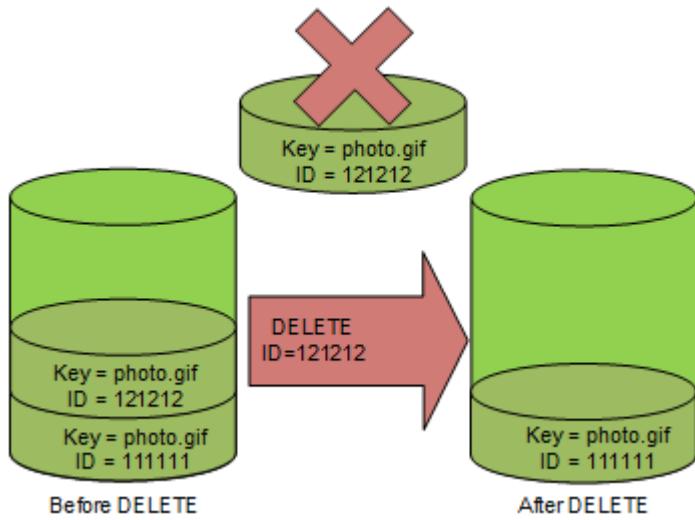

Remember that a delete marker doesn't have content, so you lose the content of the null version when a delete marker replaces it.

The following figure shows a bucket that doesn't have a null version. In this case, the DELETE removes nothing; Amazon S3 just inserts a delete marker.

Even in a versioning-suspended bucket, the bucket owner can permanently delete a specified version by including the version ID in the DELETE request. The following figure shows that deleting a specified object version permanently removes that version of the object. Only the bucket owner can delete a specified object version.

Using AWS Backup for Amazon S3

Amazon S3 is natively integrated with AWS Backup, a fully managed, policy-based service that you can use to centrally define backup policies to protect your data in Amazon S3. After you define your backup policies and assign Amazon S3 resources to the policies, AWS Backup automates the creation of Amazon S3 backups and securely stores the backups in an encrypted backup vault that you designate in your backup plan.

When using AWS Backup for Amazon S3, you can perform the following actions:

- Create continuous backups and periodic backups. Continuous backups are useful for point-in-time restore, and periodic backups are useful to meet your long-term data-retention needs.
- Automate backup scheduling and retention by centrally configuring backup policies.
- Restore backups of Amazon S3 data to a point in time that you specify.

Along with AWS Backup, you can use S3 Versioning and S3 Replication to help recover from accidental deletions and perform your own self-recovery operations.

Prerequisites

You must activate [S3 Versioning](#) on your bucket before AWS Backup can back it up.

Note

We recommend that you [set a lifecycle expiration rule for versioning-enabled buckets](#) that are being backed up. If you do not set a lifecycle expiration period, your Amazon S3 storage costs might increase because AWS Backup retains all versions of your Amazon S3 data.

Getting started

To get started with AWS Backup for Amazon S3, see [Creating Amazon S3 backups](#) in the *AWS Backup Developer Guide*.

Restrictions and limitations

To learn about the limitations, see [Creating Amazon S3 backups](#) in the *AWS Backup Developer Guide*.

Working with archived objects

To reduce your storage costs for infrequently accessed objects, you can *archive* those objects. When you archive an object, it is moved into low-cost storage, which means that you can't access it in real time.

Although archived objects are not accessible in real time, you can restore them in minutes or hours, depending on the storage class. You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the REST API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI). For instructions, see [Restoring an archived object](#).

Amazon S3 objects in the following storage classes or tiers are archived and are not accessible in real time:

- The S3 Glacier Flexible Retrieval storage class
- The S3 Glacier Deep Archive storage class
- The S3 Intelligent-Tiering Archive Access tier
- The S3 Intelligent-Tiering Deep Archive Access tier

To restore archived objects, you must do the following:

- For objects in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, you must initiate the restore request and wait until a temporary copy of the object is available. When a temporary copy of the restored object is created, the object's storage class remains the same. (A [HeadObject](#) or [GetObject](#) API operation request returns S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)
- For objects in the S3 Intelligent-Tiering Archive Access and S3 Intelligent-Tiering Deep Archive Access tiers, you must initiate the restore request and wait until the object is moved into the Frequent Access tier.

For more information about how all Amazon S3 storage classes compare, see [Using Amazon S3 storage classes](#). For more information about S3 Intelligent-Tiering, see [the section called “How S3 Intelligent-Tiering works”](#).

Restoring objects from S3 Glacier

When you use S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 restores a temporary copy of the object only for the specified duration. After that, it deletes the restored object copy. You can modify the expiration period of a restored copy by reissuing a restore request. In this case, Amazon S3 updates the expiration period relative to the current time.

 **Note**

When you restore an archived object from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, you pay for both the archived object and the copy that you restored temporarily. For information about pricing, see [Amazon S3 pricing](#).

Restoring objects from S3 Intelligent-Tiering

When you restore an object from the S3 Intelligent-Tiering Archive Access tier or S3 Intelligent-Tiering Deep Archive Access tier, the object moves back into the S3 Intelligent-Tiering Frequent Access tier. If the object is not accessed after 30 consecutive days, it automatically moves into the Infrequent Access tier. After a minimum of 90 consecutive days of no access, the object moves into the S3 Intelligent-Tiering Archive Access tier. If the object is not accessed after a minimum of 180 consecutive days, the object moves into the Deep Archive Access tier.

Note

Unlike in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, restore requests for S3 Intelligent-Tiering objects don't accept the Days value.

Using S3 Batch Operations with restore requests

To restore more than one Amazon S3 object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

Restore time

Amazon S3 calculates the expiration time of the restored object copy by adding the number of days specified in the restoration request to the time when the requested restoration is completed. Amazon S3 then rounds the resulting time to the next day at midnight Universal Coordinated Time (UTC). For example, suppose that a restored object copy was created on October 15, 2012, at 10:30 AM UTC, and the restoration period was specified as 3 days. In this case, the restored copy expires on October 19, 2012, at 00:00 UTC, at which time Amazon S3 deletes the object copy.

The time it takes a restore job to finish depends on which archive storage class or storage tier you use and which retrieval option you specify: Expedited (only available for S3 Glacier Flexible Retrieval and S3 Intelligent-Tiering Archive Access), Standard, or Bulk. For more information, see [Archive retrieval options](#).

You can be notified when your restore is complete by using Amazon S3 Event Notifications. For more information, see [Amazon S3 Event Notifications](#).

Topics

- [Archive retrieval options](#)
- [Restoring an archived object](#)

Archive retrieval options

The following are the available retrieval options when restoring an archived object in Amazon S3:

- **Expedited** – Quickly access your data that is stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. You can use this option when occasional urgent requests for a subset of archives are required. For all but the largest archived objects (250 MB+), data that is accessed by using expedited retrievals is typically made available within 1–5 minutes.

Provisioned capacity helps ensure that retrieval capacity for expedited retrievals from S3 Glacier Flexible Retrieval is available when you need it. For more information, see [Provisioned capacity](#).

- **Standard** – Access any of your archived objects within several hours. Standard is the default option for retrieval requests that do not specify the retrieval option. Standard retrievals typically finish within 3–5 hours for objects stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. These retrievals typically finish within 12 hours for objects stored in the S3 Glacier Deep Archive storage class or S3 Intelligent-Tiering Deep Archive Access tier. Standard retrievals are free for objects that are stored in S3 Intelligent-Tiering.

 **Note**

Standard retrievals initiated by using S3 Batch Operations restore operation typically start within minutes and finish within 3–5 hours for objects stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. Standard retrievals initiated by using Batch Operations for objects in S3 Glacier Deep Archive storage class or S3 Intelligent-Tiering Deep Archive Access tier typically start within 9 hours and finish within 12 hours.

- **Bulk** – Access your data by using the lowest-cost retrieval option in Amazon S3 Glacier. With Bulk retrievals, you can retrieve large amounts, even petabytes, of data inexpensively. Bulk retrievals typically finish within 5–12 hours for objects that are stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. These retrievals typically finish within 48 hours for objects stored in the S3 Glacier Deep Archive storage class or S3 Intelligent-Tiering Deep Archive Access tier. Bulk retrievals are free for objects that are stored in S3 Glacier Flexible Retrieval or S3 Intelligent-Tiering.

The following table summarizes the archive retrieval options. For information about pricing, see [Amazon S3 pricing](#).

To make an Expedited, Standard, or Bulk retrieval, set the `Tier` request element in the [RestoreObject](#) REST API operation request to the option that you want, or the equivalent in the

AWS Command Line Interface (AWS CLI) or AWS SDKs. If you purchased provisioned capacity, all Expedited retrievals are automatically served through your provisioned capacity.

Provisioned capacity

Provisioned capacity helps ensure that your retrieval capacity for Expedited retrievals from S3 Glacier Flexible Retrieval is available when you need it. Each unit of capacity provides that at least three Expedited retrievals can be performed every 5 minutes, and it provides up to 150 megabytes per second (Mbps) of retrieval throughput.

If your workload requires highly reliable and predictable access to a subset of your data in minutes, consider purchasing provisioned retrieval capacity. Without provisioned capacity, Expedited retrievals might not be accepted during periods of high demand. If you require access to Expedited retrievals under all circumstances, we recommend that you purchase provisioned retrieval capacity.

Provisioned capacity units are allocated to an AWS account. Thus, the requester of the Expedited data retrieval should purchase the provisioned capacity unit, not the bucket owner.

You can purchase provisioned capacity by using the Amazon S3 console, the Amazon S3 Glacier console, the [Purchase Provisioned Capacity](#) REST API operation, the AWS SDKs, or the AWS CLI. For provisioned capacity pricing information, see [Amazon S3 pricing](#).

S3 Glacier restore initiation request rates

When you initiate restore requests for objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, a retrieval-requests quota is applied for your AWS account. S3 Glacier supports restore requests at a rate of 1,000 transactions per second. If this rate is exceeded otherwise valid requests are throttled or rejected and Amazon S3 returns a `ThrottlingException` error.

Optionally, you can also use S3 Batch Operations to retrieve a large number of objects stored in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive with a single request. For more information, see [S3 Batch Operations basics](#).

Restoring an archived object

Amazon S3 objects in the following storage classes or tiers are archived and are not accessible in real time:

- The S3 Glacier Flexible Retrieval storage class
- The S3 Glacier Deep Archive storage class

- The S3 Intelligent-Tiering Archive Access tier
- The S3 Intelligent-Tiering Deep Archive Access tier

Amazon S3 objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes are not immediately accessible. To access an object in these storage classes, you must restore a temporary copy of the object to its S3 bucket for a specified duration (number of days). If you want a permanent copy of the object, restore the object, and then create a copy of it in your Amazon S3 bucket. Copying restored objects isn't supported in the Amazon S3 console. For this type of copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API. Unless you make a copy and change its storage class, the object will still be stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For information about using these storage classes, see [Storage classes for archiving objects](#).

To access objects in the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers, you must initiate a restore request and wait until the object is moved into the Frequent Access tier. When you restore an object from the Archive Access tier or Deep Archive Access tier, the object moves back into the Frequent Access tier. For information about using these storage classes, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).

For general information about archived objects, see [Working with archived objects](#).

 **Note**

When you restore an archived object from S3 Glacier, you pay for both the archived object and the copy that you restored temporarily. When you restore an object from S3 Intelligent-Tiering there are no retrieval charges for Standard or Bulk retrievals. Subsequent restore requests called on archived objects that have already been restored are billed as a GET request. For information about pricing, see [Amazon S3 pricing](#).

Restoring an Archived Object

You can restore an archived object by using the Amazon S3 console, the Amazon S3 REST API, the AWS SDKs, the AWS Command Line Interface (AWS CLI), or S3 Batch Operations.

Using the S3 console

Restore objects using the Amazon S3 console

Use the following procedure to Restore an object that has been archived to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, or the S3 Intelligent-Tiering Archive Access or Deep Archive Access storage tiers.

To restore an archived object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to restore.
4. In the **Objects** list, select the object or objects that you want to restore, choose **Actions**, and then choose **Initiate restore**.
5. If you're restoring from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, enter the number of days that you want your archived data to be accessible in the **Number of days that the restored copy is available** box.
6. For **Retrieval tier**, do one of the following:
 - Choose **Bulk retrieval** or **Standard retrieval**, and then choose **Initiate restore**.
 - Choose **Expedited retrieval** (available only for S3 Glacier Flexible Retrieval or S3 Intelligent-Tiering Archive Access). If you're restoring an object in S3 Glacier Flexible Retrieval, you can choose whether to buy provisioned capacity for your Expedited retrieval. If you want to purchase provisioned capacity, proceed to the next step. If you don't, choose **Initiate restore**.
7. (Optional) If you're restoring an object in S3 Glacier Flexible Retrieval and you chose **Expedited retrieval**, you can choose whether to buy provisioned capacity. Provisioned capacity is available only for objects in S3 Glacier Flexible Retrieval. If you already have provisioned capacity, choose **Initiate restore** to start a provisioned retrieval.

If you have provisioned capacity, all of your Expedited retrievals are served by your provisioned capacity. For more information, see [Provisioned capacity](#).

- If you don't have provisioned capacity and you don't want to buy it, choose **Initiate restore**.
- If you don't have provisioned capacity, but you want to buy provisioned capacity units (PCUs), choose **Purchase PCUs**. In the **Purchase PCUs** dialog box, choose how many PCUs you want to buy, confirm your purchase, and then choose **Purchase PCUs**. When you get the **Purchase succeeded** message, choose **Initiate restore** to start provisioned retrieval.

Using the AWS CLI

Restore objects from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive

The following example uses the `restore-object` command to restore the object `dir1/example.obj` in the bucket `DOC-EXAMPLE-BUCKET` for 25 days.

```
aws s3api restore-object --bucket DOC-EXAMPLE-BUCKET --key dir1/example.obj --restore-request '{"Days":25,"GlacierJobParameters":{"Tier":"Standard"}}'
```

If the JSON syntax used in the example results in an error on a Windows client, replace the restore request with the following syntax:

```
--restore-request Days=25,GlacierJobParameters={"Tier"]="Standard"}
```

Restore objects from S3 Intelligent-Tiering Archive Access and Deep Archive Access

The following example uses the `restore-object` command to restore the object `dir1/example.obj` in the bucket `DOC-EXAMPLE-BUCKET` to the Frequent Access tier.

```
aws s3api restore-object --bucket DOC-EXAMPLE-BUCKET --key dir1/example.obj --restore-request '{}'
```

Monitor restore status

To monitor the status of your `restore-object` request, use the following `head-object` command:

```
aws s3api head-object --bucket DOC-EXAMPLE-BUCKET --key dir1/example.obj
```

For more information, see [restore-object](#) in the *AWS CLI Command Reference*.

Using the REST API

Amazon S3 provides an API operation for you to initiate the restoration of an archived object. For more information, see [RestoreObject](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to restore archived objects in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive with the AWS SDKs, see [Restore an archived copy of an object back into an Amazon S3 bucket using an AWS SDK](#).

Using S3 Batch Operations

To restore more than one archived object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

To create a Batch Operations job, you must have a manifest that contains only the objects that you want to restore. You can create a manifest by using S3 Inventory, or you can supply a CSV file with the necessary information. For more information, see [the section called “Specifying a manifest”](#).

Before creating and running S3 Batch Operations jobs, you must grant permissions to Amazon S3 to perform S3 Batch Operations on your behalf. For the required permissions, see [the section called “Granting permissions”](#).

Note

Batch Operations jobs can operate either on S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage class objects *or* on S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tier objects. Batch Operations can't operate on both types of archived objects in the same job. To restore objects of both types, you *must* create separate Batch Operations jobs.

For more information about using Batch Operations to restore archive objects, see [the section called “Restore objects”](#).

To create an S3 Initiate Restore Object Batch Operations job

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. For **AWS Region**, choose the Region where you want to create your job.
5. Under **Manifest format**, choose the type of manifest to use.
 - If you choose **S3 inventory report**, enter the path to the manifest .json object that Amazon S3 generated as part of the CSV-formatted inventory report. If you want to use a

manifest version other than the most recent, enter the version ID for the manifest.json object.

- If you choose **CSV**, enter the path to a CSV-formatted manifest object. The manifest object must follow the format described in the console. If you want to use a version other than the most recent, you can optionally include the version ID for the manifest object.

6. Choose **Next**.
7. In the **Operation** section, choose **Restore**.
8. In the **Restore** section, for **Restore source**, choose either **Glacier Flexible Retrieval** or **Glacier Deep Archive** or **Intelligent-Tiering Archive Access tier** or **Deep Archive Access tier**.

If you chose **Glacier Flexible Retrieval** or **Glacier Deep Archive**, enter a number for **Number of days that the restored copy is available**.

For **Retrieval tier**, choose the tier that you want to use.

9. Choose **Next**.
10. On the **Configure additional options** page, fill out the following sections:
 - In the **Additional options** section, provide a description for the job and specify a priority number for the job. Higher numbers indicate a higher priority. For more information, see [the section called "Assigning job priority"](#).
 - In the **Completion report** section, select whether Batch Operations should create a completion report. For more information about completion reports, see [the section called "Completion reports"](#).
 - In the **Permissions** section, you must grant permissions to Amazon S3 to perform Batch Operations on your behalf. For the required permissions, see [the section called "Granting permissions"](#).
 - (Optional) In the **Job tags** section, add tags in key-value pairs. For more information, see [the section called "Using tags"](#).

When you're finished, choose **Next**.

11. On the **Review** page, verify the settings. If you need to make changes, choose **Previous**. Otherwise, choose **Create job**.

For more information about Batch Operations, see [Restore objects with Batch Operations](#) and [Creating an S3 Batch Operations job](#).

Checking restore status and expiration date

You can check the status of a restore request or the expiration date using the Amazon S3 console, AWS CLI, or REST API.

Note

Restored objects from S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are stored only for the number of days that you specify. The below procedures will return the expiration date for these copies. Objects restored from S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tiers do not have expiration dates and instead move back to the Frequent Access tier.

Using the S3 console

To check an object's restore status and expiration date in the Amazon S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you are restoring.
4. In the **Objects** list, select the object that you are restoring. The object's details page appears.
 - If the restoration isn't finished, at the top of the page, you see a section that says **Restoration in progress**.
 - If the restoration is finished, at the top of the page, you see a section that says **Restoration complete**. If you're restoring from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, this section also displays the **Restoration expiry date**. Amazon S3 will remove the restored copy of your archived object on this date.

Using the AWS CLI

Check an object's restore status and expiration date with the AWS CLI

The following example uses the head-object command to view metadata for the object *dir1/example.obj* in the bucket *DOC-EXAMPLE-BUCKET*. When you run this command on an object being restored Amazon S3 returns if the restore is ongoing and (if applicable) the expiration date.

```
aws s3api head-object --bucket DOC-EXAMPLE-BUCKET --key dir1/example.obj
```

Expected Output (Restore Ongoing):

```
{

For more information about head-object, see [head-object](#) in the *AWS CLI Reference*.

Using the REST API

Amazon S3 provides an API operation for you to retrieve object metadata. To check the restoration status and expiration date of an archived object using the REST API, see [HeadObject](#) in the *Amazon Simple Storage Service API Reference*.

Upgrading the speed of an in-progress restore

You can upgrade the speed of your restoration while it is in progress.

To upgrade an in-progress restore to a faster tier

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to restore.
4. In the **Objects** list, select the object that you are restoring. The object's details page appears. On the object's details page, choose **Upgrade retrieval tier**. For information about checking the restoration status of an object, see [Checking restore status and expiration date](#).
5. Choose the tier that you want to upgrade to, and then choose **Initiate restore**.

Using S3 Object Lock

S3 Object Lock can help prevent Amazon S3 objects from being deleted or overwritten for a fixed amount of time or indefinitely. Object Lock uses a *write-once-read-many* (WORM) model to store objects. You can use Object Lock to help meet regulatory requirements that require WORM storage, or to add another layer of protection against object changes or deletion.

Note

S3 Object Lock has been assessed by Cohasset Associates for use in environments that are subject to SEC 17a-4, CFTC, and FINRA regulations. For more information about how Object Lock relates to these regulations, see the [Cohasset Associates Compliance Assessment](#).

Object Lock provides two ways to manage object retention: *retention periods* and *legal holds*. An object version can have a retention period, a legal hold, or both.

- **Retention period** – A retention period specifies a fixed period of time during which an object remains locked. You can set a unique retention period for individual objects. Additionally, you can set a default retention period on an S3 bucket. You may also restrict the minimum and maximum allowable retention periods with the `s3:object-lock-remaining-retention-`

days condition key in the bucket policy. This helps you establish a range of retention periods and by restricting retention periods that may be shorter or longer than this range.

- **Legal hold** – A legal hold provides the same protection as a retention period, but it has no expiration date. Instead, a legal hold remains in place until you explicitly remove it. Legal holds are independent from retention periods and are placed on individual object versions.

Object Lock works only in buckets that have S3 Versioning enabled. When you lock an object version, Amazon S3 stores the lock information in the metadata for that object version. Placing a retention period or a legal hold on an object protects only the version that's specified in the request. Retention periods and legal holds don't prevent new versions of the object from being created, or delete markers to be added on top of the object. For information about S3 Versioning, see [Using versioning in S3 buckets](#).

If you put an object into a bucket that already contains an existing protected object with the same object key name, Amazon S3 creates a new version of that object. The existing protected version of the object remains locked according to its retention configuration.

How S3 Object Lock works

Topics

- [Retention periods](#)
- [Retention modes](#)
- [Legal holds](#)
- [Best practices for using S3 Object Lock](#)
- [Required permissions](#)

Retention periods

A *retention period* protects an object version for a fixed amount of time. When you place a retention period on an object version, Amazon S3 stores a timestamp in the object version's metadata to indicate when the retention period expires. After the retention period expires, the object version can be overwritten or deleted.

You can place a retention period explicitly on an individual object version or on a bucket's properties so that it applies to all objects in the bucket automatically. When you apply a retention

period to an object version explicitly, you specify a *Retain Until Date* for the object version. Amazon S3 stores this date in the object version's metadata.

You can also set a retention period in a bucket's properties. When you set a retention period on a bucket, you specify a duration, in either days or years, for how long to protect every object version placed in the bucket. When you place an object in the bucket, Amazon S3 calculates a *Retain Until Date* for the object version by adding the specified duration to the object version's creation timestamp. The object version is then protected exactly as though you explicitly placed an individual lock with that retention period on the object version.

Note

When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.

Like all other Object Lock settings, retention periods apply to individual object versions. Different versions of a single object can have different retention modes and periods.

For example, suppose that you have an object that is 15 days into a 30-day retention period, and you PUT an object into Amazon S3 with the same name and a 60-day retention period. In this case, your PUT request succeeds, and Amazon S3 creates a new version of the object with a 60-day retention period. The older version maintains its original retention period and becomes deletable in 15 days.

After you've applied a retention setting to an object version, you can extend the retention period. To do this, submit a new Object Lock request for the object version with a *Retain Until Date* that is later than the one currently configured for the object version. Amazon S3 replaces the existing retention period with the new, longer period. Any user with permissions to place an object retention period can extend a retention period for an object version. To set a retention period, you must have the `s3:PutObjectRetention` permission.

When you set a retention period on an object or S3 bucket, you must select one of two retention modes: *compliance* or *governance*.

Retention modes

S3 Object Lock provides two retention modes that apply different levels of protection to your objects:

- Compliance mode
- Governance mode

In *compliance* mode, a protected object version can't be overwritten or deleted by any user, including the root user in your AWS account. When an object is locked in compliance mode, its retention mode can't be changed, and its retention period can't be shortened. Compliance mode helps ensure that an object version can't be overwritten or deleted for the duration of the retention period.

 **Note**

The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

In *governance* mode, users can't overwrite or delete an object version or alter its lock settings unless they have special permissions. With governance mode, you protect objects against being deleted by most users, but you can still grant some users permission to alter the retention settings or delete the objects if necessary. You can also use governance mode to test retention-period settings before creating a compliance-mode retention period.

To override or remove governance-mode retention settings, you must have the `s3:BypassGovernanceRetention` permission and must explicitly include `x-amz-bypass-governance-retention:true` as a request header with any request that requires overriding governance mode.

 **Note**

By default, the Amazon S3 console includes the `x-amz-bypass-governance-retention:true` header. If you try to delete objects protected by *governance* mode and have the `s3:BypassGovernanceRetention` permission, the operation will succeed.

Legal holds

With Object Lock, you can also place a *legal hold* on an object version. Like a retention period, a legal hold prevents an object version from being overwritten or deleted. However, a legal hold

doesn't have an associated fixed amount of time and remains in effect until removed. Legal holds can be freely placed and removed by any user who has the `s3:PutObjectLegalHold` permission.

Legal holds are independent from retention periods. Placing a legal hold on an object version doesn't affect the retention mode or retention period for that object version.

For example, suppose that you place a legal hold on an object version and that object version is also protected by a retention period. If the retention period expires, the object doesn't lose its WORM protection. Rather, the legal hold continues to protect the object until an authorized user explicitly removes the legal hold. Similarly, if you remove a legal hold while an object version has a retention period in effect, the object version remains protected until the retention period expires.

Best practices for using S3 Object Lock

Consider using *Governance mode* if you want to protect objects from being deleted by most users during a pre-defined retention period, but at the same time want some users with special permissions to have the flexibility to alter the retention settings or delete the objects.

Consider using *Compliance mode* if you never want any user, including the root user in your AWS account, to be able to delete the objects during a pre-defined retention period. You can use this mode in case you have a requirement to store compliant data.

You can use *Legal Hold* when you are not sure for how long you want your objects to stay immutable. This could be because you have an upcoming external audit of your data and want to keep objects immutable till the audit is complete. Alternately, you may have an ongoing project utilizing a dataset that you want to keep immutable until the project is complete.

Required permissions

Object Lock operations require specific permissions. Depending on the exact operation that you're attempting, you might need any of the following permissions:

- `s3:BypassGovernanceRetention`
- `s3:GetBucketObjectLockConfiguration`
- `s3:GetObjectLegalHold`
- `s3:GetObjectRetention`
- `s3:PutBucketObjectLockConfiguration`
- `s3:PutObjectLegalHold`

- s3:PutObjectRetention

For a complete list of Amazon S3 permissions with descriptions, see [Actions, resources, and condition keys for Amazon S3](#).

For information about using conditions with permissions, see [Amazon S3 condition key examples](#).

Object Lock considerations

Amazon S3 Object Lock can help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely.

You can use the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API to view or set Object Lock information. For general information about S3 Object Lock capabilities, see [Using S3 Object Lock](#).

Important

- After you enable Object Lock on a bucket, you can't disable Object Lock or suspend versioning for that bucket.
- S3 buckets with Object Lock can't be used as destination buckets for server access logs.
For more information, see [the section called "Logging server access"](#).

Topics

- [Permissions for viewing lock information](#)
- [Bypassing governance mode](#)
- [Using Object Lock with S3 Replication](#)
- [Using Object Lock with Amazon S3 Inventory](#)
- [Managing S3 Lifecycle policies with Object Lock](#)
- [Managing delete markers with Object Lock](#)
- [Using S3 Storage Lens with Object Lock](#)
- [Uploading objects to an Object Lock enabled bucket](#)
- [Configuring events and notifications](#)
- [Setting limits on retention periods with a bucket policy](#)

Permissions for viewing lock information

You can programmatically view the Object Lock status of an Amazon S3 object version by using the [HeadObject](#) or [GetObject](#) operations. Both operations return the retention mode, retain until date, and legal hold status for the specified object version. Additionally, you can view the Object Lock status for multiple objects in your S3 bucket using S3 Inventory.

To view an object version's retention mode and retention period, you must have the `s3:GetObjectRetention` permission. To view an object version's legal hold status, you must have the `s3:GetObjectLegalHold` permission. To view a bucket's default retention configuration, you must have the `s3:GetBucketObjectLockConfiguration` permission. If you make a request for an Object Lock configuration on a bucket that doesn't have S3 Object Lock enabled, Amazon S3 returns an error.

Bypassing governance mode

If you have the `s3:BypassGovernanceRetention` permission, you can perform operations on object versions that are locked in governance mode as if they were unprotected. These operations include deleting an object version, shortening the retention period, or removing the Object Lock retention period by placing a new `PutObjectRetention` request with empty parameters.

To bypass governance mode, you must explicitly indicate in your request that you want to bypass this mode. To do this, include the `x-amz-bypass-governance-retention:true` header with your `PutObjectRetention` API operation request, or use the equivalent parameter with requests made through the AWS CLI or AWS SDKs. The S3 console automatically applies this header for requests made through the S3 console if you have the `s3:BypassGovernanceRetention` permission.

 **Note**

Bypassing governance mode doesn't affect an object version's legal hold status. If an object version has a legal hold enabled, the legal hold remains and prevents requests to overwrite or delete the object version.

Using Object Lock with S3 Replication

You can use Object Lock with S3 Replication to enable automatic, asynchronous copying of locked objects and their retention metadata, across S3 buckets. When you use replication, objects in a

source bucket are replicated to one or more *destination buckets*. If the source bucket has Object Lock enabled, the destination buckets must also have Object Lock enabled.

To set up replication on a bucket with Object Lock enabled, you can use the S3 console, AWS CLI, Amazon S3 REST API, or AWS SDKs.

Note

To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [Setting up permissions](#).

For general information about S3 Replication, see [Replicating objects](#).

For examples of setting up S3 Replication, see [Walkthroughs: Examples for configuring replication](#).

Using Object Lock with Amazon S3 Inventory

You can configure Amazon S3 Inventory to create lists of the objects in an S3 bucket on a defined schedule. You can configure Amazon S3 Inventory to include the following Object Lock metadata for your objects:

- The retain until date
- The retention mode
- The legal hold status

For more information, see [Amazon S3 Inventory](#).

Managing S3 Lifecycle policies with Object Lock

Object lifecycle management configurations continue to function normally on protected objects, including placing delete markers. However, a locked version of an object cannot be deleted by a S3 Lifecycle expiration policy. Object Lock is maintained regardless of which storage class the object resides in and throughout S3 Lifecycle transitions between storage classes.

For more information about managing object lifecycles, see [Managing your storage lifecycle](#).

Managing delete markers with Object Lock

Although you can't delete a protected object version, you can still create a delete marker for that object. Placing a delete marker on an object doesn't delete the object or its object versions. However, it makes Amazon S3 behave in most ways as though the object has been deleted. For more information, see [Working with delete markers](#).

 **Note**

Delete markers are not WORM-protected, regardless of any retention period or legal hold in place on the underlying object.

Using S3 Storage Lens with Object Lock

To see metrics for Object Lock-enabled storage bytes and object count, you can use Amazon S3 Storage Lens. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity.

For more information, see [Using S3 Storage Lens to protect your data](#).

For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Uploading objects to an Object Lock enabled bucket

The Content-MD5 header is required for any request to upload an object with a retention period configured using Object Lock. The MD5 digest is a way to verify the integrity of your object after uploading it to a bucket. After uploading the object, Amazon S3 calculates the MD5 digest of the object and compares it to the value that you provided. The request succeeds only if the two digests match. The S3 console automatically adds this header, however you must specify this header when using the [PutObject](#) API.

For more information, see [Using Content-MD5 when uploading objects](#).

Configuring events and notifications

You can use Amazon S3 Event Notifications to track access and changes to your Object Lock configurations and data by using AWS CloudTrail. For information about CloudTrail, see [What is AWS CloudTrail?](#) in the *AWS CloudTrail User Guide*.

You can also use Amazon CloudWatch to generate alerts based on this data. For information about CloudWatch, see the [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*.

Setting limits on retention periods with a bucket policy

You can set minimum and maximum allowable retention periods for a bucket by using a bucket policy. The maximum retention period is 100 years.

The following example shows a bucket policy that uses the `s3:object-lock-remaining-retention-days` condition key to set a maximum retention period of 10 days.

```
{  
    "Version": "2012-10-17",  
    "Id": "SetRetentionLimits",  
    "Statement": [  
        {  
            "Sid": "SetRetentionPeriod",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": [  
                "s3:PutObjectRetention"  
            ],  
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET1/*",  
            "Condition": {  
                "NumericGreaterThan": {  
                    "s3:object-lock-remaining-retention-days": "10"  
                }  
            }  
        }  
    ]  
}
```

Note

If your bucket is the destination bucket for a replication configuration, you can set up minimum and maximum allowable retention periods for object replicas that are created by using replication. To do so, you must allow the `s3:ReplicateObject` action in your bucket policy. For more information about replication permissions, see [the section called “Setting up permissions”](#).

For more information about bucket policies, see the following topics:

- [Actions, resources, and condition keys for Amazon S3](#)
- [Example — Object operations](#)
- [Amazon S3 condition key examples](#)

Configuring S3 Object Lock

With Amazon S3 Object Lock, you can store objects in Amazon S3 by using a *write-once-read-many* (WORM) model. You can use S3 Object Lock to prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. For general information about Object Lock capabilities, see [Using S3 Object Lock](#).

Before you lock any objects, you must enable S3 Versioning and Object Lock on a bucket. Afterward, you can set a retention period, a legal hold, or both.

To work with Object Lock, you must have certain permissions. For a list of the permissions related to various Object Lock operations, see [the section called “Required permissions”](#).

Important

- After you enable Object Lock on a bucket, you can't disable Object Lock or suspend versioning for that bucket.
- S3 buckets with Object Lock can't be used as destination buckets for server access logs. For more information, see [the section called “Logging server access”](#).

Topics

- [Enable Object Lock when creating a new S3 bucket](#)
- [Enable Object Lock on an existing S3 bucket](#)
- [Set or modify a legal hold on an S3 object](#)
- [Set or modify a retention period on an S3 object](#)
- [Set or modify a default retention period on an S3 bucket](#)

Enable Object Lock when creating a new S3 bucket

You can enable Object Lock when creating a new S3 bucket by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.

The **Create bucket** page opens.

4. For **Bucket name**, enter a name for your bucket.

 **Note**

After you create a bucket, you can't change its name. For more information about naming buckets, see [Bucket naming rules](#).

5. For **Region**, choose the AWS Region where you want the bucket to reside.
6. Under **Object Ownership**, choose to disable or enable access control lists (ACLs) and control ownership of objects uploaded in your bucket.
7. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.
8. Under **Bucket Versioning**, choose **Enabled**.

Object Lock works only with versioned buckets.

9. (Optional) Under **Tags**, you can choose to add tags to your bucket. Tags are key-value pairs that are used to categorize storage and allocate costs.
10. Under **Advanced settings**, find **Object Lock** and choose **Enable**.

You must acknowledge that enabling Object Lock will permanently allow objects in this bucket to be locked.

11. Choose **Create bucket**.

Using the AWS CLI

The following `create-bucket` example creates a new S3 bucket named `DOC-EXAMPLE-BUCKET1` with Object Lock enabled:

```
aws s3api create-bucket --bucket DOC-EXAMPLE-BUCKET1 --object-lock-enabled-for-bucket
```

For more information and examples, see [create-bucket](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to create a new S3 bucket with Object Lock enabled. For more information, see [CreateBucket](#) in the *Amazon Simple Storage Service API Reference*.

Enable Object Lock on an existing S3 bucket

You can enable Object Lock for an existing S3 bucket by using the Amazon S3 console, the AWS CLI, AWS SDKs, or Amazon S3 REST API.

Using the S3 console

Note

Object Lock works only with versioned buckets.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to enable Object Lock on.

4. Choose the **Properties** tab.
5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
6. Under **Object Lock**, choose **Enable**.

You must acknowledge that enabling Object Lock will permanently allow objects in this bucket to be locked.

7. Choose **Save changes**.

Using the AWS CLI

The following `put-object-lock-configuration` example command sets a 50-day Object Lock retention period on a bucket named `DOC-EXAMPLE-BUCKET1`:

```
aws s3api put-object-lock-configuration --bucket DOC-EXAMPLE-BUCKET1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled", "Rule": {"DefaultRetention": {"Mode": "COMPLIANCE", "Days": 50 }}}'
```

For more information and examples, see [put-object-lock-configuration](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the Amazon S3 REST API to enable Object Lock on an existing S3 bucket. For more information, see [PutObjectLockConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

Set or modify a legal hold on an S3 object

You can set or remove a legal hold on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

Important

- If you want to set a legal hold on an object, the object's bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.

For more information, see [the section called “Legal holds”](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to set or modify a legal hold on.
4. In the **Objects** list, select the object that you want to set or modify a legal hold on.
5. On the **Object properties** page, find the **Object Lock legal hold** section, and choose **Edit**.
6. Choose **Enable** to set a legal hold or **Disable** to remove a legal hold.
7. Choose **Save changes**.

Using the AWS CLI

The following put-object-legal-hold example sets a legal hold on the object *my-image.fs* in the bucket named *DOC-EXAMPLE-BUCKET1*:

```
aws s3api put-object-legal-hold --bucket DOC-EXAMPLE-BUCKET1 --key my-image.fs --legal-hold="Status=ON"
```

The following put-object-legal-hold example removes a legal hold on the object *my-image.fs* in the bucket named *DOC-EXAMPLE-BUCKET1*:

```
aws s3api put-object-legal-hold --bucket DOC-EXAMPLE-BUCKET1 --key my-image.fs --legal-hold="Status=OFF"
```

For more information and examples, see [put-object-legal-hold](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set or modify a legal hold on an object. For more information, see [PutObjectLegalHold](#) in the *Amazon Simple Storage Service API Reference*.

Set or modify a retention period on an S3 object

You can set or modify a retention period on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

Important

- If you want to set a retention period on an object, the object's bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.
- The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

For more information, see [Retention periods](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.

3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to set or modify a retention period on.
4. In the **Objects** list, select the object that you want to set or modify a retention period on.
5. On the **Object properties** page, find the **Object Lock retention** section, and choose **Edit**.
6. Under **Retention**, choose **Enable** to set a retention period or **Disable** to remove a retention period.
7. If you chose **Enable**, under **Retention mode**, choose either **Governance mode** or **Compliance mode**. For more information, see [Retention modes](#).
8. Under **Retain until date**, choose the date that you want to have the retention period end on. During this period, your object is WORM-protected and can't be overwritten or deleted. For more information, see [Retention periods](#).
9. Choose **Save changes**.

Using the AWS CLI

The following put-object-retention example sets a retention period on the object *my-image.fs* in the bucket named *DOC-EXAMPLE-BUCKET1* until January 1, 2025:

```
aws s3api put-object-retention --bucket DOC-EXAMPLE-BUCKET1 --key my-image.fs --  
retention='{ "Mode": "GOVERNANCE", "RetainUntilDate": "2025-01-01T00:00:00" }'
```

For more information and examples, see [put-object-retention](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set a retention period on an object. For more information, see [PutObjectRetention](#) in the *Amazon Simple Storage Service API Reference*.

Set or modify a default retention period on an S3 bucket

You can set or modify a default retention period on an S3 bucket by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API. You specify a duration, in either days or years, for how long to protect every object version placed in the bucket.

Important

- If you want to set a default retention period on a bucket, the bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.
- The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

For more information, see [Retention periods](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to set or modify a default retention period on.
4. Choose the **Properties** tab.
5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
6. Under **Default retention**, choose **Enable** to set a default retention or **Disable** to remove a default retention.
7. If you chose **Enable**, under **Retention mode**, choose either **Governance mode** or **Compliance mode**. For more information, see [Retention modes](#).
8. Under **Default retention period**, choose the number of days or years that you want the retention period to last for. Objects placed in this bucket will be locked for this number of days or years. For more information, see [Retention periods](#).
9. Choose **Save changes**.

Using the AWS CLI

The following put-object-lock-configuration example command sets a 50-day Object Lock retention period on the bucket named **DOC-EXAMPLE-BUCKET1** by using compliance mode:

```
aws s3api put-object-lock-configuration --bucket DOC-EXAMPLE-BUCKET1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled", "Rule": {"DefaultRetention": {"Mode": "COMPLIANCE", "Days": 50 }}}'
```

The following put-object-lock-configuration example removes the default retention configuration on a bucket:

```
aws s3api put-object-lock-configuration --bucket DOC-EXAMPLE-BUCKET1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled"}'
```

For more information and examples, see [put-object-lock-configuration](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to enable Object Lock on an existing S3 bucket. For more information, see [PutObjectLockConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

Using Amazon S3 storage classes

Each object in Amazon S3 has a storage class associated with it. For example, if you list the objects in an S3 bucket, the console shows the storage class for all the objects in the list. Amazon S3 offers a range of storage classes for the objects that you store. You choose a class depending on your use case scenario and performance access requirements. All of these storage classes offer high durability.

The following sections provide details of the various storage classes and how to set the storage class for your objects.

Topics

- [Storage classes for frequently accessed objects](#)
- [Storage class for automatically optimizing data with changing or unknown access patterns](#)
- [Storage classes for infrequently accessed objects](#)
- [Storage classes for archiving objects](#)
- [Storage class for Amazon S3 on Outposts](#)
- [Comparing the Amazon S3 storage classes](#)
- [Setting the storage class of an object](#)

Storage classes for frequently accessed objects

For performance-sensitive use cases (those that require millisecond access time) and frequently accessed data, Amazon S3 provides the following storage classes:

- **S3 Standard** – The default storage class. If you don't specify the storage class when you upload an object, Amazon S3 assigns the S3 Standard storage class.
- **S3 Express One Zone** – Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the lowest latency cloud object storage class available today, with data access speed up to 10x faster and with request costs 50 percent lower than S3 Standard. With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. For more information, see [What is S3 Express One Zone?](#).
- **Reduced Redundancy** – The Reduced Redundancy Storage (RRS) storage class is designed for noncritical, reproducible data that can be stored with less redundancy than the S3 Standard storage class.

Important

We recommend not using this storage class. The S3 Standard storage class is more cost-effective.

For durability, RRS objects have an average annual expected loss of 0.01 percent of objects. If an RRS object is lost, when requests are made to that object, Amazon S3 returns a 405 error.

Storage class for automatically optimizing data with changing or unknown access patterns

S3 Intelligent-Tiering is an Amazon S3 storage class that's designed to optimize storage costs by automatically moving data to the most cost-effective access tier, without performance impact or operational overhead. S3 Intelligent-Tiering is the only cloud storage class that delivers automatic cost savings by moving data on a granular object level between access tiers when access patterns change. S3 Intelligent-Tiering is the ideal storage class when you want to optimize storage costs for data that has unknown or changing access patterns. There are no retrieval fees for S3 Intelligent-Tiering.

For a small monthly object monitoring and automation fee, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers. S3 Intelligent-Tiering delivers automatic storage cost savings in three low-latency and high-throughput access tiers. For data that can be accessed asynchronously, you can choose to activate automatic archiving capabilities within the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is designed for 99.9% availability and 99.99999999% durability.

S3 Intelligent-Tiering automatically stores objects in three access tiers:

- **Frequent Access** – Objects that are uploaded or transitioned to S3 Intelligent-Tiering are automatically stored in the Frequent Access tier.
- **Infrequent Access** – S3 Intelligent-Tiering moves objects that have not been accessed in 30 consecutive days to the Infrequent Access tier.
- **Archive Instant Access** – With S3 Intelligent-Tiering, any existing objects that have not been accessed for 90 consecutive days are automatically moved to the Archive Instant Access tier.

In addition to these three tiers, S3 Intelligent-Tiering offers two optional archive access tiers:

- **Archive Access** – S3 Intelligent-Tiering provides you with the option to activate the Archive Access tier for data that can be accessed asynchronously. After activation, the Archive Access tier

automatically archives objects that have not been accessed for a minimum of 90 consecutive days.

- **Deep Archive Access** – S3 Intelligent-Tiering provides you with the option to activate the Deep Archive Access tier for data that can be accessed asynchronously. After activation, the Deep Archive Access tier automatically archives objects that have not been accessed for a minimum of 180 consecutive days.

 **Note**

- Only activate the Archive Access tier for 90 days if you want to bypass the Archive Instant Access tier. The Archive Access tier delivers slightly lower-cost storage with minute-to-hour retrieval times. The Archive Instant Access tier delivers millisecond access and high-throughput performance.
- Activate the Archive Access and Deep Archive Access tiers only if your objects can be accessed asynchronously by your application. If the object that you are retrieving is stored in the Archive Access or Deep Archive Access tiers, first restore the object by using `RestoreObject`.

You can [move newly created data to S3 Intelligent-Tiering](#), setting it as your default storage class. You can also choose to activate one or both of the archive access tiers by using the [PutBucketIntelligentTieringConfiguration](#) API operation, the AWS CLI, or the Amazon S3 console. For more information about using S3 Intelligent-Tiering and activating the archive access tiers, see [Using S3 Intelligent-Tiering](#).

To access objects in the Archive Access or Deep Archive Access tiers, you first need to restore them. For more information, see [Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers](#).

 **Note**

If the size of an object is less than 128 KB, it is not monitored and not eligible for auto-tiering. Smaller objects are always stored in the Frequent Access tier. For more information about S3 Intelligent-Tiering, see [S3 Intelligent-Tiering access tiers](#).

Storage classes for infrequently accessed objects

The **S3 Standard-IA** and **S3 One Zone-IA** storage classes are designed for long-lived and infrequently accessed data. (IA stands for *infrequent access*.) S3 Standard-IA and S3 One Zone-IA objects are available for millisecond access (similar to the S3 Standard storage class). Amazon S3 charges a retrieval fee for these objects, so they are most suitable for infrequently accessed data. For pricing information, see [Amazon S3 pricing](#).

For example, you might choose the S3 Standard-IA and S3 One Zone-IA storage classes to do the following:

- For storing backups.
- For older data that is accessed infrequently, but that still requires millisecond access. For example, when you upload data, you might choose the S3 Standard storage class, and use lifecycle configuration to tell Amazon S3 to transition the objects to the S3 Standard-IA or S3 One Zone-IA class.

For more information about lifecycle management, see [Managing your storage lifecycle](#).

Note

The S3 Standard-IA and S3 One Zone-IA storage classes are suitable for objects larger than 128 KB that you plan to store for at least 30 days. If an object is less than 128 KB, Amazon S3 charges you for 128 KB. If you delete an object before the end of the 30-day minimum storage duration period, you are charged for 30 days. Objects that are deleted, overwritten, or transitioned to a different storage class before 30 days will incur the normal storage usage charge plus a pro-rated charge for the remainder of the 30-day minimum. For pricing information, see [Amazon S3 pricing](#).

These storage classes differ as follows:

- **S3 Standard-IA** – Amazon S3 stores the object data redundantly across multiple geographically separated Availability Zones (similar to the S3 Standard storage class). S3 Standard-IA objects are resilient to the loss of an Availability Zone. This storage class offers greater availability and resiliency than the S3 One Zone-IA class.

- **S3 One Zone-IA** – Amazon S3 stores the object data in only one Availability Zone, which makes it less expensive than S3 Standard-IA. However, the data is not resilient to the physical loss of the Availability Zone resulting from disasters, such as earthquakes and floods. The S3 One Zone-IA storage class is as durable as S3 Standard-IA, but it is less available and less resilient. For a comparison of storage class durability and availability, see [Comparing the Amazon S3 storage classes](#) at the end of this section. For pricing information, see [Amazon S3 pricing](#).

We recommend the following:

- **S3 Standard-IA** – Use for your primary or only copy of data that can't be re-created.
- **S3 One Zone-IA** – Use if you can re-create the data if the Availability Zone fails, and for object replicas when configuring S3 Cross-Region Replication (CRR).

Storage classes for archiving objects

The **S3 Glacier Instant Retrieval**, **S3 Glacier Flexible Retrieval**, and **S3 Glacier Deep Archive** storage classes are designed for low-cost data archiving. These storage classes offer the same durability and resiliency as the S3 Standard and S3 Standard-IA storage classes. For a comparison of storage class durability and availability, see [Comparing the Amazon S3 storage classes](#).

These storage classes differ as follows:

- **S3 Glacier Instant Retrieval** – Use for archiving data that is rarely accessed and requires milliseconds retrieval. Data stored in the S3 Glacier Instant Retrieval storage class offers a cost savings compared to the S3 Standard-IA storage class, with the same latency and throughput performance as the S3 Standard-IA storage class. S3 Glacier Instant Retrieval has higher data access costs than S3 Standard-IA.

For pricing information, see [Amazon S3 pricing](#).

- **S3 Glacier Flexible Retrieval** – Use for archives where portions of the data might need to be retrieved in minutes. Data stored in the S3 Glacier Flexible Retrieval storage class has a minimum storage duration period of 90 days and can be accessed in as little as 1-5 minutes by using an expedited retrieval. The retrieval time is flexible, and you can request free bulk retrievals in up to 5-12 hours. If you delete, overwrite, or transition the object to a different storage class before the 90-day minimum, you are charged for 90 days. Amazon S3 supports restore requests at a rate of up to 1,000 transactions per second, per AWS account for S3 Glacier Flexible Retrieval.

For pricing information, see [Amazon S3 pricing](#).

- **S3 Glacier Deep Archive** – Use for archiving data that rarely needs to be accessed. Data stored in the S3 Glacier Deep Archive storage class has a minimum storage duration period of 180 days and a default retrieval time of 12 hours. If you delete, overwrite, or transition the object to a different storage class before the 180-day minimum, you are charged for 180 days. Amazon S3 supports restore requests at a rate of up to 1,000 transactions per second, per AWS account for S3 Glacier Deep Archive.

For pricing information, see [Amazon S3 pricing](#).

S3 Glacier Deep Archive is the lowest-cost storage option in AWS. Storage costs for S3 Glacier Deep Archive are less expensive than using the S3 Glacier Flexible Retrieval storage class. You can reduce S3 Glacier Deep Archive retrieval costs by using bulk retrieval, which returns data within 48 hours.

Retrieving archived objects

You can set the storage class of an object to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive in the same ways that you do for the other storage classes as described in the section [Setting the storage class of an object](#). However, S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive objects are not available for real-time access. You must first restore S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive objects before you can access them. (S3 Standard, Reduced Redundancy Storage (RRS), S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, and S3 Intelligent-Tiering objects are available for anytime access.) For more information about retrieving archived objects, see [Restoring an archived object](#).

Important

When you choose the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, your objects remain in Amazon S3. You can't access them directly through the separate Amazon S3 Glacier service.

To learn more about the Amazon S3 Glacier service, see the [Amazon S3 Glacier Developer Guide](#).

Getting started with S3 Glacier storage classes

To learn more about how to use Amazon S3 Glacier storage classes, see [Tutorial: Getting started using the Amazon S3 Glacier storage classes](#).

Storage class for Amazon S3 on Outposts

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use the same API operations and features on AWS Outposts as you do on Amazon S3, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API.

S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS). The S3 Outposts storage class is available only for objects stored in buckets on Outposts. If you try to use this storage class with an S3 bucket in an AWS Region, an `InvalidStorageClass` error occurs. In addition, if you try to use other S3 storage classes with objects stored in S3 on Outposts buckets, the same error occurs.

Objects stored in the S3 Outposts (OUTPOSTS) storage class are always encrypted by using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

You can also explicitly choose to encrypt objects stored in the S3 Outposts storage class by using server-side encryption with customer-provided encryption keys (SSE-C). For more information, see [Using server-side encryption with customer-provided keys \(SSE-C\)](#).

 **Note**

S3 on Outposts doesn't support server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

For more information about S3 on Outposts, see [What is Amazon S3 on Outposts?](#)

Comparing the Amazon S3 storage classes

The following table compares the storage classes, including their availability, durability, minimum storage duration, and other considerations.

Storage Class	Designed for	Durability (designed for)	Availability (designed for)	Availability Zones	Min storage duration	Min billable object size	Other Considerations
STANDARD	Frequently accessed data	99.999999999%	99.99%	>= 3	None	None	None
STANDARD_IA	Long-lived, infrequently accessed data	99.999999999%	99.9%	>= 3	30 days	128 KB	Per GB retrieval fees apply.
INTELLIGENT_TIERING	Long-lived data with changing or unknown access patterns	99.999999999%	99.9%	>= 3	30 days	None	Monitoring and automation fees per object apply. No retrieval fees.
ONEZONE_IA	Long-lived, infrequently accessed, non-critical data	99.999999999%	99.5%	1	30 days	128 KB	Per GB retrieval fees apply. Not resilient to the loss of the Availability Zone.
GLACIER	Long-term data archiving with retrieval times ranging from minutes to hours	99.999999999%	99.99% (after you restore objects)	>= 3	90 days	None	Per GB retrieval fees apply. You must first restore archived objects before you can access them. For more information, see Restoring Archived Objects .
DEEP_ARCHIVE	Archiving rarely accessed data with a default retrieval time of 12 hours	99.999999999%	99.99% (after you restore objects)	>= 3	180 days	None	Per GB retrieval fees apply. You must first restore archived objects before you can access them. For more information, see Restoring Archived Objects .
RRS (Not recommended)	Frequently accessed, non-critical data	99.99%	99.99%	>= 3	None	None	None

* S3 Glacier Flexible Retrieval requires 40 KB of additional metadata for each archived object. This includes 32 KB of metadata charged at the S3 Glacier Flexible Retrieval rate (required to identify and retrieve your data), and an additional 8 KB data charged at the S3 Standard rate. The S3 Standard rate is required to maintain the user-defined name and metadata for objects archived to S3 Glacier Flexible Retrieval. For more information about storage classes, see [Amazon S3 storage classes](#).

** S3 Glacier Deep Archive requires 40 KB of additional metadata for each archived object. This includes 32 KB of metadata charged at the S3 Glacier Deep Archive rate (required to identify and retrieve your data), and an additional 8 KB data charged at the S3 Standard rate. The S3 Standard rate is required to maintain the user-defined name and metadata for objects archived to Amazon S3 Glacier Deep Archive. For more information about storage classes, see [Amazon S3 storage classes](#).

Be aware that all of the storage classes except for S3 One Zone-IA and S3 Express One Zone are designed to be resilient to the physical loss of an Availability Zone resulting from disasters. Also, consider costs, in addition to the performance requirements of your application scenario. For storage class pricing, see [Amazon S3 pricing](#).

Setting the storage class of an object

To set and update object storage classes, you can use the Amazon S3 console, AWS SDKs, or the AWS Command Line Interface (AWS CLI). All of these approaches use Amazon S3 API operations to send requests to Amazon S3.

Amazon S3 API operations support setting (or updating) the storage class of objects as follows:

- When creating a new object, you can specify its storage class. For example, when creating objects by using the [PUT Object](#), [POST Object](#), and [Initiate Multipart Upload](#) API operations, you add the `x-amz-storage-class` request header to specify a storage class. If you don't add this header, Amazon S3 uses S3 Standard, the default storage class.
- You can also change the storage class of an object that is already stored in Amazon S3 to any other storage class by making a copy of the object by using the [PUT Object - Copy](#) API operation. However, you can't use [PUT Object - Copy](#) to copy objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. You also can't transition from S3 One Zone-IA to S3 Glacier Instant Retrieval.

You copy the object in the same bucket by using the same key name and specifying the request headers as follows:

- Set the `x-amz-metadata-directive` header to COPY.
- Set the `x-amz-storage-class` header to the storage class that you want to use.

In a versioning-enabled bucket, you can't change the storage class of a specific version of an object. When you copy the object, Amazon S3 gives it a new version ID.

- You can change an object's storage class using the Amazon S3 console if the object size is less than 160GB. If larger, we recommend adding an S3 Lifecycle configuration to change the object's storage class.
- You can direct Amazon S3 to change the storage class of objects by adding an S3 Lifecycle configuration to a bucket. For more information, see [Managing your storage lifecycle](#).
- When setting up a replication configuration, you can set the storage class for replicated objects to any other storage class. However, you can't replicate objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For more information, see [Replication configuration](#).

Restricting access policy permissions to a specific storage class

When you grant access policy permissions for Amazon S3 operations, you can use the `s3:x-amz-storage-class` condition key to restrict which storage class to use when storing uploaded objects. For example, when you grant the `s3:PutObject` permission, you can restrict object uploads to a specific storage class. For an example policy, see [Example 5: Restricting object uploads to objects with a specific storage class](#).

For more information about using conditions in policies and a complete list of Amazon S3 condition keys, see the following topics:

- [Actions, resources, and condition keys for Amazon S3](#)
- [Amazon S3 condition key examples](#)

Amazon S3 Intelligent-Tiering

The S3 Intelligent-Tiering storage class is designed to optimize storage costs by automatically moving data to the most cost-effective access tier when access patterns change, without operational overhead or impact on performance. For a small monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers.

S3 Intelligent-Tiering delivers automatic storage cost savings in three low latency and high throughput access tiers. For data that can be accessed asynchronously, you can choose to activate automatic archiving capabilities within the S3 Intelligent-Tiering storage class. There are no retrieval charges in S3 Intelligent-Tiering. If an object in the Infrequent Access tier or Archive Instant Access tier is accessed later, it is automatically moved back to the Frequent Access tier. No additional tiering charges apply when objects are moved between access tiers within the S3 Intelligent-Tiering storage class.

S3 Intelligent-Tiering is the recommended storage class for data with unknown, changing, or unpredictable access patterns, independent of object size or retention period, such as data lakes, data analytics, and new applications.

For information about using S3 Intelligent-Tiering, see the following sections:

Topics

- [How S3 Intelligent-Tiering works](#)
- [Using S3 Intelligent-Tiering](#)
- [Managing S3 Intelligent-Tiering](#)

How S3 Intelligent-Tiering works

The Amazon S3 Intelligent-Tiering storage class automatically stores objects in three access tiers. One tier is optimized for frequent access, one lower-cost tier is optimized for infrequent

access, and another very low-cost tier is optimized for rarely accessed data. For a low monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects to the Infrequent Access tier when they haven't been accessed for 30 consecutive days. After 90 days of no access, the objects are moved to the Archive Instant Access tier without performance impact or operational overhead.

To get the lowest storage cost for data that can be accessed in minutes to hours, activate archiving capabilities to add two additional access tiers. You can tier down objects to the Archive Access tier, the Deep Archive Access tier, or both. With Archive Access, S3 Intelligent-Tiering moves objects that have not been accessed for a minimum of 90 consecutive days to the Archive Access tier. With Deep Archive Access, S3 Intelligent-Tiering moves objects to the Deep Archive Access tier after a minimum of 180 consecutive days of no access. For both tiers, you can configure the number of days of no access based on your needs.

The following actions constitute access that prevents tiering your objects down to the Archive Access tier or the Deep Archive Access tier:

- Downloading or copying an object through the Amazon S3 console.
- Invoking [CopyObject](#), [UploadPartCopy](#), or replicating objects with S3 Batch Replication. In these cases, the source objects of the copy or replication operations are tiered up.
- Invoking [GetObject](#), [PutObject](#), [RestoreObject](#), [CompleteMultipartUpload](#), [ListParts](#), or [SelectObjectContent](#).

For example, if your objects are accessed through `SelectObjectContent` before your specified number of days of no access (for example, 180 days), that action resets the timer. Your objects won't move to the Archive Access tier or the Deep Archive Access tier until the time after the last `SelectObjectContent` request reaches your specified number of days.

If an object in the Infrequent Access tier or Archive Instant Access tier is accessed later, it is automatically moved back to the Frequent Access tier.

The following actions constitute access that automatically moves objects from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier:

- Downloading or copying an object through the Amazon S3 console.
- Invoking [CopyObject](#), [UploadPartCopy](#), or replicating objects with Batch Replication. In these cases, the source objects of the copy or replication operations are tiered up.
- Invoking [GetObject](#), [PutObject](#), [RestoreObject](#), [CompleteMultipartUpload](#), or [ListParts](#).

Other actions **don't** constitute access that automatically moves objects from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier. The following is a sample, not a definitive list, of such actions:

- Invoking [HeadObject](#), [GetObjectTagging](#), [PutObjectTagging](#), [ListObjects](#), [ListObjectsV2](#), or [ListObjectVersions](#).
- Invoking [SelectObjectContent](#) doesn't constitute access that tiers objects up to a Frequent Access tier. In addition, it doesn't prevent tiering objects down from the Frequent Access tier to the Infrequent Access tier, and then to the Archive Instant Access tier.

You can configure S3 Intelligent-Tiering as your default storage class for newly created data by specifying INTELLIGENT-TIERING in your [PutBucketIntelligentTieringConfiguration](#) request header. S3 Intelligent-Tiering is designed for 99.9% availability and 99.999999999% durability.

 **Note**

If the size of an object is less than 128 KB, it is not monitored and is not eligible for automatic tiering. Smaller objects are always stored in the Frequent Access tier.

S3 Intelligent-Tiering access tiers

The following section explains the different automatic and optional access tiers. When objects move between access tiers, the storage class remains the same (S3 Intelligent-Tiering).

Frequent Access tier (automatic)

This is the default access tier that any object created or transitioned to S3 Intelligent-Tiering begins its lifecycle in. An object remains in this tier as long as it is being accessed. The Frequent Access tier provides low latency and high-throughput performance.

Infrequent Access tier (automatic)

If an object is not accessed for 30 consecutive days, the object moves to the Infrequent Access tier. The Infrequent Access tier provides low latency and high-throughput performance.

Archive Instant Access tier (automatic)

If an object is not accessed for 90 consecutive days, the object moves to the Archive Instant Access tier. The Archive Instant Access tier provides low latency and high-throughput performance.

Archive Access tier (optional)

S3 Intelligent-Tiering provides you with the option to activate the Archive Access tier for data that can be accessed asynchronously. After activation, the Archive Access tier automatically archives objects that have not been accessed for a minimum of 90 consecutive days. You can extend the last access time for archiving to a maximum of 730 days. The Archive Access tier has the same performance as the [S3 Glacier Flexible Retrieval](#) storage class.

Standard retrieval times for this access tier can range from 3–5 hours. If you initiate your restore request by using S3 Batch Operations, your restore starts within minutes. For more information about retrieval options and times, see [the section called “ Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers”](#).

Note

Only activate the Archive Access tier for 90 days if you want to bypass the Archive Instant Access tier. The Archive Access tier delivers slightly lower storage costs, with minute-to-hour retrieval times. The Archive Instant Access tier delivers millisecond access and high-throughput performance.

Deep Archive Access tier (optional)

S3 Intelligent-Tiering provides you with the option to activate the Deep Archive Access tier for data that can be accessed asynchronously. After activation, the Deep Archive Access tier automatically archives objects that have not been accessed for a minimum of 180 consecutive days. You can extend the last access time for archiving to a maximum of 730 days. The Deep Archive Access tier has the same performance as the [S3 Glacier Deep Archive](#) storage class.

Standard retrieval of objects in this access tier occurs within 12 hours. If you initiate your restore request by using S3 Batch Operations, your restore starts within 9 hours. For more information about retrieval options and times, see [the section called “ Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers”](#).

Note

Activate the Archive Access and Deep Archive Access tiers only if your objects can be accessed asynchronously by your application. If the object that you are retrieving is stored in the Archive Access or Deep Archive Access tiers, you must first restore the object by using the `RestoreObject` operation.

Using S3 Intelligent-Tiering

You can use the S3 Intelligent-Tiering storage class to automatically optimize storage costs. S3 Intelligent-Tiering delivers automatic cost savings by moving data on a granular object level between access tiers when access patterns change. For data that can be accessed asynchronously, you can choose to enable automatic archiving within the S3 Intelligent-Tiering storage class using the AWS Management Console, AWS CLI, or Amazon S3 API.

Moving data to S3 Intelligent-Tiering

There are two ways to move data into S3 Intelligent-Tiering. You can directly [PUT](#) data into S3 Intelligent-Tiering by specifying `INTELLIGENT_TIERING` in the `x-amz-storage-class` header or configure S3 Lifecycle configurations to transition objects from S3 Standard or S3 Standard-Infrequent Access to S3 Intelligent-Tiering.

Uploading data to S3 Intelligent-Tiering using Direct PUT

When you upload an object to the S3 Intelligent-Tiering storage class using the [PUT](#) API operation, you specify S3 Intelligent-Tiering in the [`x-amz-storage-class`](#) request header.

The following request stores the image, `my-image.jpg`, in the `myBucket` bucket. The request uses the `x-amz-storage-class` header to request that the object is stored using the S3 Intelligent-Tiering storage class.

Example

```
PUT /my-image.jpg HTTP/1.1
Host: myBucket.s3.<Region>.amazonaws.com (http://amazonaws.com/)
Date: Wed, 1 Sep 2021 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
```

```
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: INTELLIGENT_TIERING
```

Transitioning data to S3 Intelligent-Tiering from S3 Standard or S3 Standard-Infrequent Access using S3 Lifecycle

You can add rules to an S3 Lifecycle configuration to tell Amazon S3 to transition objects from one storage class to another. For information on supported transitions and related constraints, see [Transitioning objects using S3 Lifecycle](#).

You can specify S3 Lifecycle configurations at the bucket or prefix level. In this S3 Lifecycle configuration rule, the filter specifies a key prefix (documents/). Therefore, the rule applies to objects with key name prefix documents/, such as documents/doc1.txt and documents/doc2.txt. The rule specifies a Transition action directing Amazon S3 to transition objects to the S3 Intelligent-Tiering storage class 0 days after creation. In this case, objects are eligible for transition to S3 Intelligent-Tiering at midnight UTC following creation.

Example

```
<LifecycleConfiguration>
  <Rule>
    <ID>ExampleRule</ID>
    <Filter>
      <Prefix>documents/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>INTELLIGENT_TIERING</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

Enabling S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers

To get the lowest storage cost on data that can be accessed in minutes to hours, you can activate one or both of the archive access tiers by creating a bucket, prefix, or object tag level configuration using the AWS Management Console, AWS CLI, or Amazon S3 API.

Using the S3 console

To enable S3 Intelligent-Tiering automatic archiving

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. Choose **Properties**.
4. Navigate to the **S3 Intelligent-Tiering Archive configurations** section and choose **Create configuration**.
5. In the **Archive configuration settings** section, specify a descriptive configuration name for your S3 Intelligent-Tiering Archive configuration.
6. Under **Choose a configuration scope**, choose a configuration scope to use. Optionally, you can limit the configuration scope to specified objects within a bucket using a shared prefix, object tag, or combination of the two.
 - a. To limit the scope of the configuration, select **Limit the scope of this configuration using one or more filters**.
 - b. To limit the scope of the configuration using a single prefix, enter the prefix under **Prefix**.
 - c. To limit the scope of the configuration using object tags, select **Add tag** and enter a value for **Key**.
7. Under **Status**, select **Enable**.
8. In the **Archive settings** section, select one or both of the Archive Access tiers to enable.
9. Choose **Create**.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Intelligent-Tiering configurations:

- [delete-bucket-intelligent-tiering-configuration](#)
- [get-bucket-intelligent-tiering-configuration](#)
- [list-bucket-intelligent-tiering-configurations](#)
- [put-bucket-intelligent-tiering-configuration](#)

For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#).

When using the AWS CLI, you cannot specify the configuration as an XML file. You must specify the JSON instead. The following is an example XML S3 Intelligent-Tiering configuration and equivalent JSON that you can specify in an AWS CLI command.

The following example puts an S3 Intelligent-Tiering configuration to the specified bucket.

Example put-bucket-intelligent-tiering-configuration

JSON

```
{  
    "Id": "string",  
    "Filter": {  
        "Prefix": "string",  
        "Tag": {  
            "Key": "string",  
            "Value": "string"  
        },  
        "And": {  
            "Prefix": "string",  
            "Tags": [  
                {  
                    "Key": "string",  
                    "Value": "string"  
                }  
                ...  
            ]  
        }  
    },  
    "Status": "Enabled"|"Disabled",  
    "Tierings": [  
        {  
            "Days": integer,  
            "AccessTier": "ARCHIVE_ACCESS"|"DEEP_ARCHIVE_ACCESS"  
        }  
        ...  
    ]  
}
```

XML

```
PUT /?intelligent-tiering&id=Id HTTP/1.1  
Host: Bucket.s3.amazonaws.com
```

```
<?xml version="1.0" encoding="UTF-8"?>
<IntelligentTieringConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Id>string</Id>
  <Filter>
    <And>
      <Prefix>string</Prefix>
      <Tag>
        <Key>string</Key>
        <Value>string</Value>
      </Tag>
      ...
    </And>
    <Prefix>string</Prefix>
    <Tag>
      <Key>string</Key>
      <Value>string</Value>
    </Tag>
  </Filter>
  <Status>string</Status>
  <Tiering>
    <AccessTier>string</AccessTier>
    <Days>integer</Days>
  </Tiering>
  ...
</IntelligentTieringConfiguration>
```

Using the PUT API operation

You can use the [PutBucketIntelligentTieringConfiguration](#) operation for a specified bucket and up to 1,000 S3 Intelligent-Tiering configurations per bucket. You can define which objects within a bucket are eligible for the archive access tiers using a shared prefix or object tag. Using a shared prefix or object tag allows you to align to specific business applications, workflows, or internal organizations. You also have the flexibility to activate the Archive Access tier, the Deep Archive Access tier, or both.

Getting started with S3 Intelligent-Tiering

To learn more about how to use S3 Intelligent-Tiering, see [Tutorial: Getting started using S3 Intelligent-Tiering](#).

Managing S3 Intelligent-Tiering

The S3 Intelligent-Tiering storage class delivers automatic storage cost savings in three low-latency and high-throughput access tiers. It also offers optional archive capabilities to help you get the lowest storage costs in the cloud for data that can be accessed in minutes to hours. The S3 Intelligent-Tiering storage class supports all Amazon S3 features, including the following:

- S3 Inventory, for verifying the access tier of objects
- S3 Replication, for replicating data to any AWS Region
- S3 Storage Lens, for viewing storage usage and activity metrics
- Server-side encryption, for protecting object data
- S3 Object Lock, for preventing accidental deletion of data
- AWS PrivateLink, for accessing Amazon S3 through a private endpoint in a virtual private cloud (VPC)

Identifying which S3 Intelligent-Tiering access tier objects are stored in

To get a list of your objects and their corresponding metadata, including their S3 Intelligent-Tiering access tier, you can use [Amazon S3 Inventory](#). S3 Inventory provides CSV, ORC, or Parquet output files that list your objects and their corresponding metadata. You can receive these inventory reports on either a daily or weekly basis for an Amazon S3 bucket or a shared prefix. (*Shared prefix* refers to objects that have names that begin with a common string.)

Viewing the archive status of an object within S3 Intelligent-Tiering

To receive notice when an object within the S3 Intelligent-Tiering storage class has moved to either the Archive Access tier or the Deep Archive Access tier, you can set up S3 Event Notifications. For more information, see [Enabling event notifications](#).

Amazon S3 can publish event notifications to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

The following is an example of a message that Amazon S3 sends to publish an `s3:IntelligentTiering` event. For more information, see [Event message structure](#).

{

```
"Records": [
    {
        "eventVersion": "2.3",
        "eventSource": "aws:s3",
        "awsRegion": "us-west-2",
        "eventTime": "1970-01-01T00:00:00.000Z",
        "eventName": "IntelligentTiering",
        "userIdentity": {
            "principalId": "s3.amazonaws.com"
        },
        "requestParameters": {
            "sourceIPAddress": "s3.amazonaws.com"
        },
        "responseElements": {
            "x-amz-request-id": "C3D13FE58DE4C810",
            "x-amz-id-2": "FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/
JRWeUWerMUE5JgHvAN0jpD"
        },
        "s3": {
            "s3SchemaVersion": "1.0",
            "configurationId": "testConfigRule",
            "bucket": {
                "name": "mybucket",
                "ownerIdentity": {
                    "principalId": "A3NL1K0ZZKExample"
                },
                "arn": "arn:aws:s3:::mybucket"
            },
            "object": {
                "key": "HappyFace.jpg",
                "size": 1024,
                "eTag": "d41d8cd98f00b204e9800998ecf8427e",
            }
        },
        "intelligentTieringEventData": {
            "destinationAccessTier": "ARCHIVE_ACCESS"
        }
    }
]
```

You can also use a [HEAD object request](#) to view an object's archive status. If an object is stored in the S3 Intelligent-Tiering storage class and is in one of the archive tiers, the HEAD object response

shows the current archive tier. To show the archive tier, the request uses the [x-amz-archive-status](#) header.

The following HEAD object request returns the metadata of an object (in this case, *my-image.jpg*).

Example

```
HEAD /my-image.jpg HTTP/1.1
Host: bucket.s3.region.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:02236Q3V0RonhpaBX5sCYVf1bNRuU=
```

You can also use HEAD object requests to monitor the status of a `restore-object` request. If the archive restoration is in progress, the HEAD object response includes the [x-amz-restore](#) header.

The following sample HEAD object response shows an object archived by using S3 Intelligent-Tiering with a restore request in progress.

Example

```
HTTP/1.1 200 OK
x-amz-id-2: FSVaTMjrmBp3Izs1NnwBZeum19ii8UbxBmi0A8AirHANJBo+hEftBuiESACOMJp
x-amz-request-id: E5CEFCB143EB505A
Date: Fri, 13 Nov 2020 00:28:38 GMT
Last-Modified: Mon, 15 Oct 2012 21:58:07 GMT
ETag: "1accb31fcf202eba0c0f41fa2f09b4d7"
x-amz-storage-class: 'INTELLIGENT_TIERING'
x-amz-archive-status: 'ARCHIVE_ACCESS'
x-amz-restore: 'ongoing-request="true"'
x-amz-restore-request-date: 'Fri, 13 Nov 2020 00:20:00 GMT'
Accept-Ranges: bytes
Content-Type: binary/octet-stream
Content-Length: 300
Server: AmazonS3
```

Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers

To access objects in the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers, you must initiate the [restore request](#), and then wait until the object is moved into the Frequent Access tier. For more information about archived objects, see [Working with archived objects](#).

When you restore an object from the Archive Access tier or Deep Archive Access tier, the object moves back into the Frequent Access tier. Afterwards, if the object isn't accessed for 30 consecutive days, it automatically moves into the Infrequent Access tier. Then, after a minimum of 90 consecutive days of no access, the object moves into the Archive Access tier. After a minimum of 180 consecutive days of no access, the object moves into the Deep Archive Access tier. For more information, see [the section called "How S3 Intelligent-Tiering works"](#).

 **Note**

When you restore an object from S3 Intelligent-Tiering there are no retrieval charges for Standard or Bulk retrievals. Subsequent restore requests called on archived objects that have already been restored are billed as a GET request. For information about pricing, see [Amazon S3 pricing](#).

The following table summarizes archived object retrieval speeds.

 **Note**

[Expedited retrievals](#) are a premium feature available for the S3 Intelligent-Tiering Archive Access tier and are charged at the Expedited request and retrieval rate. For information about Amazon S3 pricing, see [Amazon S3 Pricing](#).

You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the REST API, and the AWS Command Line Interface (AWS CLI).

Using the S3 console

To restore an object by using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to restore.
3. In the **Objects** list, select the check box next to one or more of the objects that you are restoring. Choose **Actions**, and then choose **Restore from S3 Intelligent-Tiering Archive Access or Deep Archive Access**.

4. Choose Restore.

 **Note**

Objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers are automatically restored to the Frequent Access tier.

Using the AWS CLI

To restore objects from the S3 Intelligent-Tiering Archive Access or Deep Archive Access tiers, use the `restore-object` command.

The following example command restores the object `dir1/example.obj` in the `DOC-EXAMPLE-BUCKET` bucket. To use this example command, replace the `user input placeholders` with your own information.

```
aws s3api restore-object --bucket DOC-EXAMPLE-BUCKET --key dir1/example.obj --restore-request '{}'
```

To monitor the status of your `restore-object` request, you can use the following example command. To use this example command, replace the `user input placeholders` with your own information.

```
aws s3api head-object --bucket DOC-EXAMPLE-BUCKET --key dir1/example.obj
```

For more information, see [restore-object](#) in the *AWS CLI Command Reference*.

 **Note**

Unlike in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, restore requests for S3 Intelligent-Tiering objects don't accept the Days value.

Using the REST API

Amazon S3 provides an API operation for you to initiate an archive restoration. For more information, see [RestoreObject](#) in the *Amazon Simple Storage Service API Reference*.

Using S3 Batch Operations

To restore more than one archived object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

To create a Batch Operations job, you must have a manifest that contains only the objects that you want to restore. You can create a manifest by using S3 Inventory, or you can supply a CSV file with the necessary information. For more information, see [the section called “Specifying a manifest”](#).

Before creating and running S3 Batch Operations jobs, you must grant permissions to Amazon S3 to perform S3 Batch Operations on your behalf. For the required permissions, see [the section called “Granting permissions”](#).

Note

Batch Operations jobs can operate either on S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage class objects *or* on S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tier objects. Batch Operations can't operate on both types of archived objects in the same job. To restore objects of both types, you *must* create separate Batch Operations jobs.

For more information about using Batch Operations to restore archive objects, see [the section called “Restore objects”](#).

To create an S3 Initiate Restore Object Batch Operations job

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. For **AWS Region**, choose the Region where you want to create your job.
5. Under **Manifest format**, choose the type of manifest to use.
 - If you choose **S3 inventory report**, enter the path to the manifest .json object that Amazon S3 generated as part of the CSV-formatted inventory report. If you want to use a

manifest version other than the most recent, enter the version ID for the manifest.json object.

- If you choose **CSV**, enter the path to a CSV-formatted manifest object. The manifest object must follow the format described in the console. If you want to use a version other than the most recent, you can optionally include the version ID for the manifest object.

6. Choose **Next**.
7. In the **Operation** section, choose **Restore**.
8. In the **Restore** section, for **Restore source**, choose **Intelligent-Tiering Archive Access tier or Deep Archive Access tier**. For **Retrieval tier**, choose the tier that you want to use.
9. Choose **Next**.
10. On the **Configure additional options** page, fill out the following sections:

- In the **Additional options** section, provide a description for the job and specify a priority number for the job. Higher numbers indicate a higher priority. For more information, see [the section called "Assigning job priority"](#).
- In the **Completion report** section, select whether Batch Operations should create a completion report. For more information about completion reports, see [the section called "Completion reports"](#).
- In the **Permissions** section, you must grant permissions to Amazon S3 to perform Batch Operations on your behalf. For the required permissions, see [the section called "Granting permissions"](#).
- (Optional) In the **Job tags** section, add tags in key-value pairs. For more information, see [the section called "Using tags"](#).

When you're finished, choose **Next**.

11. On the **Review** page, verify the settings. If you need to make changes, choose **Previous**. Otherwise, choose **Create job**.

For more information about Batch Operations, see [Restore objects with Batch Operations](#) and [Creating an S3 Batch Operations job](#).

Checking the restore status of an object

You can check the progress of your object's restoration on the object's detail page on the Amazon S3 console, the AWS CLI, or the REST API. For more information, see [Checking restore status and expiration date](#).

You can be notified of object restoration completion by using the `s3:ObjectRestore:Completed` action with the [Amazon S3 Event Notifications](#) feature.

Managing your storage lifecycle

To manage your objects so that they are stored cost effectively throughout their lifecycle, configure their *Amazon S3 Lifecycle*. An *S3 Lifecycle configuration* is a set of rules that define actions that Amazon S3 applies to a group of objects. There are two types of actions:

- **Transition actions** – These actions define when objects transition to another storage class. For example, you might choose to transition objects to the S3 Standard-IA storage class 30 days after creating them, or archive objects to the S3 Glacier Flexible Retrieval storage class one year after creating them. For more information, see [Using Amazon S3 storage classes](#).

There are costs associated with lifecycle transition requests. For pricing information, see [Amazon S3 pricing](#).

- **Expiration actions** – These actions define when objects expire. Amazon S3 deletes expired objects on your behalf.

Lifecycle expiration costs depend on when you choose to expire objects. For more information, see [Expiring objects](#).

If there is any delay between when an object becomes eligible for a lifecycle action and when Amazon S3 transfers or expires your object, billing changes are applied as soon as the object becomes eligible for the lifecycle action. For example, if an object is scheduled to expire and Amazon S3 does not immediately expire the object, you won't be charged for storage after the expiration time. The one exception to this behavior is if you have a lifecycle rule to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes do not occur until the object has transitioned to S3 Intelligent-Tiering.

For more information about S3 Lifecycle rules, see [Lifecycle configuration elements](#).

To get detailed metrics for S3 Lifecycle, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. S3 Storage Lens provides S3 Lifecycle rule-count metrics and metrics that you can use to identify buckets with S3 Versioning enabled or a high percentage of noncurrent version bytes. For more information, see [Using S3 Storage Lens to optimize your storage costs](#).

Managing object lifecycle

Define S3 Lifecycle configuration rules for objects that have a well-defined lifecycle. For example:

- If you upload periodic logs to a bucket, your application might need them for a week or a month. After that, you might want to delete them.
- Some documents are frequently accessed for a limited period of time. After that, they are infrequently accessed. At some point, you might not need real-time access to them, but your organization or regulations might require you to archive them for a specific period. After that, you can delete them.
- You might upload some types of data to Amazon S3 primarily for archival purposes. For example, you might archive digital media, financial and healthcare records, raw genomics sequence data, long-term database backups, and data that must be retained for regulatory compliance.

With S3 Lifecycle configuration rules, you can tell Amazon S3 to transition objects to less-expensive storage classes, or archive or delete them.

Creating a lifecycle configuration

An S3 Lifecycle configuration is an XML file that consists of a set of rules with predefined actions that you want Amazon S3 to perform on objects during their lifetime.

You can also configure the lifecycle by using the Amazon S3 console, REST API, AWS SDKs, and the AWS Command Line Interface (AWS CLI). For more information, see [Setting lifecycle configuration on a bucket](#).

Amazon S3 provides a set of REST API operations for managing lifecycle configuration on a bucket. Amazon S3 stores the configuration as a *lifecycle subresource* that is attached to your bucket. For details, see the following:

[PUT Bucket lifecycle](#)

[GET Bucket lifecycle](#)

[DELETE Bucket lifecycle](#)

For more information about creating a lifecycle configuration, see the following topics:

Topics

- [Transitioning objects using Amazon S3 Lifecycle](#)
- [Expiring objects](#)
- [Setting lifecycle configuration on a bucket](#)
- [Lifecycle and other bucket configurations](#)
- [Configuring Lifecycle event notifications](#)
- [Lifecycle configuration elements](#)
- [Examples of S3 Lifecycle configuration](#)

Transitioning objects using Amazon S3 Lifecycle

You can add rules in an S3 Lifecycle configuration to tell Amazon S3 to transition objects to another Amazon S3 storage class. For more information about storage classes, see [Using Amazon S3 storage classes](#). Some examples of when you might use S3 Lifecycle configurations in this way include the following:

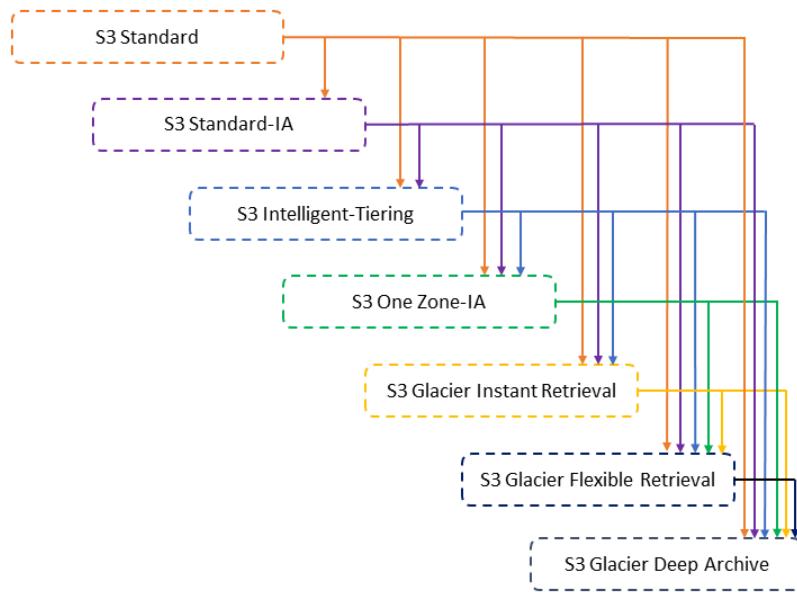

- When you know that objects are infrequently accessed, you might transition them to the S3 Standard-IA storage class.
- You might want to archive objects that you don't need to access in real time to the S3 Glacier Flexible Retrieval storage class.

The following sections describe supported transitions, related constraints, and transitioning to the S3 Glacier Flexible Retrieval storage class.

Supported transitions and related constraints

In an S3 Lifecycle configuration, you can define rules to transition objects from one storage class to another to save on storage costs. When you don't know the access patterns of your objects, or if your access patterns are changing over time, you can transition the objects to the S3 Intelligent-Tiering storage class for automatic cost savings. For information about storage classes, see [Using Amazon S3 storage classes](#).

Amazon S3 supports a waterfall model for transitioning between storage classes, as shown in the following diagram.

Supported lifecycle transitions

Amazon S3 supports the following lifecycle transitions between storage classes using an S3 Lifecycle configuration.

You *can transition* from the following:

- The S3 Standard storage class to any other storage class.
- The S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
- The S3 Intelligent-Tiering storage class to the S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
- The S3 One Zone-IA storage class to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.
- The S3 Glacier Instant Retrieval storage class to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.
- The S3 Glacier Flexible Retrieval storage class to the S3 Glacier Deep Archive storage class.

- Any storage class to the S3 Glacier Deep Archive storage class.

Note

There are no data retrieval charges for lifecycle transitions. However, there are per-request ingest charges when using PUT, COPY, or lifecycle rules to move data into any S3 storage class. Consider the ingest or transition cost before moving objects into any storage class.

For more information about cost considerations, see [Amazon S3 pricing](#).

Unsupported lifecycle transitions

Amazon S3 does not support any of the following lifecycle transitions.

You *can't transition* from the following:

- Any storage class to the S3 Standard storage class.
- Any storage class to the Reduced Redundancy Storage (RRS) class.
- The S3 Intelligent-Tiering storage class to the S3 Standard-IA storage class.
- The S3 One Zone-IA storage class to the S3 Intelligent-Tiering, S3 Standard-IA, or S3 Glacier Instant Retrieval storage classes.

Constraints

Lifecycle storage class transitions have the following constraints:

Object Size and Transitions from S3 Standard or S3 Standard-IA to S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA

When you transition objects from the S3 Standard or S3 Standard-IA storage classes to S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA, the following object size constraints apply:

- **Larger objects** – For the following transitions, there is a cost benefit to transitioning larger objects:
 - From the S3 Standard or S3 Standard-IA storage classes to S3 Intelligent-Tiering.
 - From the S3 Standard storage class to S3 Standard-IA or S3 One Zone-IA.
- **Objects smaller than 128 KiB** – For the following transitions, Amazon S3 does not transition objects that are smaller than 128 KiB:

- From the S3 Standard or S3 Standard-IA storage classes to S3 Intelligent-Tiering or S3 Glacier Instant Retrieval.
- From the S3 Standard storage class to S3 Standard-IA or S3 One Zone-IA.

 **Note**

You can filter lifecycle rules based on object size.

 **Important**

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets](#).

Minimum Days for Transition to S3 Standard-IA or S3 One Zone-IA

Before you transition objects to S3 Standard-IA or S3 One Zone-IA, you must store them for at least 30 days in Amazon S3. For example, you cannot create a Lifecycle rule to transition objects to the S3 Standard-IA storage class one day after you create them. Amazon S3 doesn't support this transition within the first 30 days because newer objects are often accessed more frequently or deleted sooner than is suitable for S3 Standard-IA or S3 One Zone-IA storage.

Similarly, if you are transitioning noncurrent objects (in versioned buckets), you can transition only objects that are at least 30 days noncurrent to S3 Standard-IA or S3 One Zone-IA storage. For a list of minimum storage duration for all storage class, see [Comparing the Amazon S3 storage classes](#).

Minimum 30-Day Storage Charge for S3 Standard-IA and S3 One Zone-IA

The S3 Standard-IA and S3 One Zone-IA storage classes have a minimum 30-day storage charge. Therefore, you can't specify a single Lifecycle rule for both an S3 Standard-IA or S3 One Zone-IA transition and an S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive transition when the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive transition occurs less than 30 days after the S3 Standard-IA or S3 One Zone-IA transition.

The same 30-day minimum applies when you specify a transition from S3 Standard-IA storage to S3 One Zone-IA. You can specify two rules to accomplish this, but you pay minimum storage charges. For more information about cost considerations, see [Amazon S3 pricing](#).

Manage an object's complete lifecycle

You can combine these S3 Lifecycle actions to manage an object's complete lifecycle. For example, suppose that the objects you create have a well-defined lifecycle. Initially, the objects are frequently accessed for a period of 30 days. Then, objects are infrequently accessed for up to 90 days. After that, the objects are no longer needed, so you might choose to archive or delete them.

In this scenario, you can create an S3 Lifecycle rule in which you specify the initial transition action to S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage, another transition action to S3 Glacier Flexible Retrieval storage for archiving, and an expiration action. As you move the objects from one storage class to another, you save on storage cost. For more information about cost considerations, see [Amazon S3 pricing](#).

Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes (object archival)

Using S3 Lifecycle configuration, you can transition objects to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes for archiving. When you choose the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, your objects remain in Amazon S3. You cannot access them directly through the separate Amazon S3 Glacier service. For more general information about S3 Glacier see, [What is Amazon S3 Glacier](#) in the *Amazon S3 Glacier Developer Guide*.

Before you archive objects, review the following sections for relevant considerations.

General considerations

The following are the general considerations for you to consider before you archive objects:

- Encrypted objects remain encrypted throughout the storage class transition process.
- Objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes are not available in real time.

Archived objects are Amazon S3 objects, but before you can access an archived object, you must first restore a temporary copy of it. The restored object copy is available only for the duration you specify in the restore request. After that, Amazon S3 deletes the temporary copy, and the object remains archived in S3 Glacier Flexible Retrieval.

You can restore an object by using the Amazon S3 console or programmatically by using the AWS SDK wrapper libraries or the Amazon S3 REST API in your code. For more information, see [Restoring an archived object](#).

- Objects that are stored in the S3 Glacier Flexible Retrieval storage class can only be transitioned to the S3 Glacier Deep Archive storage class.

You can use an S3 Lifecycle configuration rule to convert the storage class of an object from S3 Glacier Flexible Retrieval to the S3 Glacier Deep Archive storage class only. If you want to change the storage class of an object that is stored in S3 Glacier Flexible Retrieval to a storage class other than S3 Glacier Deep Archive, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, or Reduced Redundancy as the storage class.

- The transition of objects to the S3 Glacier Deep Archive storage class can go only one way.

You cannot use an S3 Lifecycle configuration rule to convert the storage class of an object from S3 Glacier Deep Archive to any other storage class. If you want to change the storage class of an archived object to another storage class, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Reduced Redundancy Storage as the storage class.

 **Note**

The Copy operation for restored objects isn't supported in the Amazon S3 console for objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For

this type of Copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API.

The objects that are stored in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes are visible and available only through Amazon S3. They are not available through the separate Amazon S3 Glacier service.

These are Amazon S3 objects, and you can access them only by using the Amazon S3 console or the Amazon S3 API. You cannot access the archived objects through the separate Amazon S3 Glacier console or the Amazon S3 Glacier API.

Cost considerations

If you are planning to archive infrequently accessed data for a period of months or years, the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes can reduce your storage costs. However, to ensure that the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class is appropriate for you, consider the following:

- **Storage overhead charges** – When you transition objects to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, a fixed amount of storage is added to each object to accommodate metadata for managing the object.
 - For each object archived to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. Amazon S3 stores this metadata so that you can get a real-time list of your archived objects by using the Amazon S3 API. For more information, see [Get Bucket \(List Objects\)](#). You are charged S3 Standard rates for this additional storage.
 - For each object that is archived to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rates for this additional storage.

If you are archiving small objects, consider these storage charges. Also consider aggregating many small objects into a smaller number of large objects to reduce overhead costs.

- **Number of days you plan to keep objects archived** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are long-term archival solutions. The minimal storage duration period is 90 days for the S3 Glacier Flexible Retrieval storage class and 180 days for S3 Glacier Deep

Archive. Deleting data that is archived to Amazon S3 Glacier doesn't incur charges if the objects you delete are archived for more than the minimal storage duration period. If you delete or overwrite an archived object within the minimal duration period, Amazon S3 charges a prorated early deletion fee. For information about the early deletion fee, see the "How am I charged for deleting objects from Amazon S3 Glacier that are less than 90 days old?" question on the [Amazon S3 FAQ](#).

- **S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive transition request charges** – Each object that you transition to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class constitutes one transition request. There is a cost for each such request. If you plan to transition a large number of objects, consider the request costs. If you are archiving a mix of objects that includes small objects, especially those under 128KB, we recommend using the lifecycle object size filter to filter out small objects from your transition to reduce request costs. S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive do not automatically block transition of objects under 128KB.
- **S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive data restore charges** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are designed for long-term archival of data that you access infrequently. For information about data restoration charges, see the "How much does it cost to retrieve data from Amazon S3 Glacier?" question on the [Amazon S3 FAQ](#). For information about how to restore data from Amazon S3 Glacier, see [Restoring an archived object](#).

When you archive objects to Amazon S3 Glacier by using S3 Lifecycle management, Amazon S3 transitions these objects asynchronously. There might be a delay between the transition date in the S3 Lifecycle configuration rule and the date of the physical transition. You are charged Amazon S3 Glacier prices based on the transition date specified in the rule. For more information, see the Amazon S3 Glacier section of the [Amazon S3 FAQ](#).

The Amazon S3 product detail page provides pricing information and example calculations for archiving Amazon S3 objects. For more information, see the following topics:

- "How is my storage charge calculated for Amazon S3 objects archived to Amazon S3 Glacier?" on the [Amazon S3 FAQ](#).
- "How am I charged for deleting objects from Amazon S3 Glacier that are less than 90 days old?" on the [Amazon S3 FAQ](#).
- "How much does it cost to retrieve data from Amazon S3 Glacier?" on the [Amazon S3 FAQ](#).
- [Amazon S3 pricing](#) for storage costs for the different storage classes.

Restoring archived objects

Archived objects are not accessible in real time. You must first initiate a restore request and then wait until a temporary copy of the object is available for the duration that you specify in the request. After you receive a temporary copy of the restored object, the object's storage class remains S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. (A [HEAD Object](#) or [GET Object](#) API operation request will return S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)

Note

When you restore an archive, you are paying for both the archive (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rate) and a copy that you restored temporarily (S3 Standard storage rate). For information about pricing, see [Amazon S3 pricing](#).

You can restore an object copy programmatically or by using the Amazon S3 console. Amazon S3 processes only one restore request at a time per object. For more information, see [Restoring an archived object](#).

Expiring objects

When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 takes an action based on which state the bucket is in.

- **Non-versioned bucket** – Amazon S3 queues the object for removal and removes it asynchronously, permanently removing the object.
- **Versioning-enabled bucket** – If the current object version is not a delete marker, Amazon S3 adds a delete marker with a unique version ID. This makes the current version noncurrent, and the delete marker the current version.
- **Versioning-suspended bucket** – Amazon S3 creates a delete marker with null as the version ID. This delete marker replaces any object version with a null version ID in the version hierarchy, which effectively deletes the object.

For a versioned bucket (that is, versioning-enabled or versioning-suspended), there are several considerations that guide how Amazon S3 handles the Expiration action. For versioning-enabled or versioning-suspended buckets, the following applies:

- Object expiration applies only to an object's current version (it has no impact on noncurrent object versions).
- Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
- If the current object version is the only object version and it is also a delete marker (also referred as an *expired object delete marker*, where all object versions are deleted and you only have a delete marker remaining), Amazon S3 removes the expired object delete marker. You can also use the expiration action to direct Amazon S3 to remove any expired object delete markers. For example, see [Example 7: Removing expired object delete markers](#).

For more information, see [Using versioning in S3 buckets](#).

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets](#).

How to find when objects will expire

To find when an object is scheduled to expire, use the [HEAD Object](#) or [GET Object](#) API operation. These API operations return response headers that provide the date and time at which the object is no longer cacheable.

Note

- There may be a delay between the expiration date and the date at which Amazon S3 removes an object. You are not charged for expiration or the storage time associated with an object that has expired.
- Prior to updating, disabling, or deleting Lifecycle rules, use the LIST API operations (such as [ListObjectsV2](#), [ListObjectVersions](#), and [ListMultipartUploads](#)) or [Amazon S3 Inventory](#) to verify that Amazon S3 has transitioned and expired eligible objects based on your use cases.

Minimum storage duration charge

If you create an S3 Lifecycle expiration rule that causes objects that have been in S3 Standard-IA or S3 One Zone-IA storage for less than 30 days to expire, you are charged for 30 days. If you create a Lifecycle expiration rule that causes objects that have been in S3 Glacier Flexible Retrieval storage for less than 90 days to expire, you are charged for 90 days. If you create a Lifecycle expiration rule that causes objects that have been in S3 Glacier Deep Archive storage for less than 180 days to expire, you are charged for 180 days.

For more information, see [Amazon S3 pricing](#).

Setting lifecycle configuration on a bucket

This section explains how you can set a S3 Lifecycle configuration on a bucket using AWS SDKs, the AWS CLI, or the Amazon S3 console. For information about S3 Lifecycle configuration, see [Managing your storage lifecycle](#).

You can use lifecycle rules to define actions that you want Amazon S3 to take during an object's lifetime (for example, transition objects to another storage class, archive them, or delete them after a specified period of time).

Before you set a lifecycle configuration, note the following:

Propagation delay

When you add an S3 Lifecycle configuration to a bucket, there is usually some lag before a new or updated Lifecycle configuration is fully propagated to all the Amazon S3 systems. Expect a delay of

a few minutes before the configuration fully takes effect. This delay can also occur when you delete an S3 Lifecycle configuration.

Disabling or deleting Lifecycle rules

When you disable or delete Lifecycle rules, Amazon S3 stops scheduling new objects for deletion or transition after a small delay. Any objects that were already scheduled are unscheduled and are not deleted or transitioned.

Note

Prior to updating, disabling, or deleting Lifecycle rules, use the LIST API operations (such as [ListObjectsV2](#), [ListObjectVersions](#), and [ListMultipartUploads](#)) or [Amazon S3 Inventory](#) to verify that Amazon S3 has transitioned and expired eligible objects based on your use cases. If you're experiencing any issues with updating, disabling, or deleting Lifecycle rules, see [Troubleshoot Amazon S3 Lifecycle issues](#).

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects with a specific prefix to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old.

Changes in billing

There may be a lag between when the Lifecycle configuration rules are satisfied and when the action triggered by satisfying the rule is taken. However, changes in billing happen as soon as the Lifecycle configuration rule is satisfied, even if the action is not yet taken.

For example, after the object expiration time, you are not charged for storage, even if the object is not deleted immediately. Another example, as soon as the object transition time elapses, you are charged S3 Glacier Flexible Retrieval storage rates, even if the object is not immediately transitioned to the S3 Glacier Flexible Retrieval storage class. Lifecycle transitions to the S3 Intelligent-Tiering storage class are the exception. Changes in billing do not happen until the object has transitioned into the S3 Intelligent-Tiering storage class.

Using the S3 console

You can define a lifecycle rules for all objects or a subset of objects in the bucket by using a shared prefix (objects names that begin with a common string) or a tag. Using a lifecycle rule you can define actions specific to current and non-current object versions. For more information, see the following:

- [Managing your storage lifecycle](#)
- [Using versioning in S3 buckets](#)

To create a lifecycle rule

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to create a lifecycle rule for.
3. Choose the **Management** tab, and choose **Create lifecycle rule**.
4. In **Lifecycle rule name**, enter a name for your rule.

The name must be unique within the bucket.

5. Choose the scope of the lifecycle rule:
 - To apply this lifecycle rule to *all objects with a specific prefix or tag*, choose **Limit the scope to specific prefixes or tags**.
 - To limit the scope by prefix, in **Prefix**, enter the prefix.
 - To limit the scope by tag, choose **Add tag**, and enter the tag key and value.

For more information about object name prefixes, see [Creating object key names](#). For more information about object tags, see [Categorizing your storage using tags](#).

6. To filter a rule by object size, you can check **Specify minimum object size**, **Specify maximum object size**, or both options.
 - When you're specifying a **minimum object size** or **maximum object size**, the value must be larger than 0 bytes and up to 5TB. You can specify this value in bytes, KB, MB, or GB.
 - When you're specifying both, the maximum object size must be larger than the minimum object size.

7. Under **Lifecycle rule actions**, choose the actions that you want your lifecycle rule to perform:

- Transition *current* versions of objects between storage classes
- Transition *previous* versions of objects between storage classes
- Expire *current* versions of objects
- Permanently delete *previous* versions of objects
- Delete expired delete markers or incomplete multipart uploads

Depending on the actions that you choose, different options appear.

8. To transition *current* versions of objects between storage classes, under **Transition current versions of objects between storage classes**:

a. In **Storage class transitions**, choose the storage class to transition to:

- Standard-IA
- Intelligent-Tiering
- One Zone-IA
- S3 Glacier Flexible Retrieval
- Glacier Deep Archive

b. In **Days after object creation**, enter the number of days after creation to transition the object.

For more information about storage classes, see [Using Amazon S3 storage classes](#). You can define transitions for current or previous object versions or for both current and previous versions. Versioning enables you to keep multiple versions of an object in one bucket. For more information about versioning, see [Using the S3 console](#).

 **Important**

When you choose the S3 Glacier Flexible Retrieval or Glacier Deep Archive storage class, your objects remain in Amazon S3. You cannot access them directly through the separate Amazon S3 Glacier service. For more information, see [Transitioning objects using Amazon S3 Lifecycle](#).

9. To transition *non-current* versions of objects between storage classes, under **Transition non-current versions of objects between storage classes**:
 - a. In **Storage class transitions**, choose the storage class to transition to:
 - Standard-IA
 - Intelligent-Tiering
 - One Zone-IA
 - S3 Glacier Flexible Retrieval
 - Glacier Deep Archive
 - b. In **Days after object becomes non-current**, enter the number of days after creation to transition the object.
10. To expire *current* versions of objects, under **Expire current versions of objects**, in **Number of days after object creation**, enter the number of days.

 **Important**

In a non-versioned bucket the expiration action results in Amazon S3 permanently removing the object. For more information about lifecycle actions, see [Elements to describe lifecycle actions](#).

11. To permanently delete previous versions of objects, under **Permanently delete noncurrent versions of objects**, in **Days after objects become noncurrent**, enter the number of days. You can optionally specify the number of newer versions to retain by entering a value under **Number of newer versions to retain**.
12. Under **Delete expired delete markers or incomplete multipart uploads**, choose **Delete expired object delete markers** and **Delete incomplete multipart uploads**. Then, enter the number of days after the multipart upload initiation that you want to end and clean up incomplete multipart uploads.

For more information about multipart uploads, see [Uploading and copying objects using multipart upload](#).

13. Choose **Create rule**.

If the rule does not contain any errors, Amazon S3 enables it, and you can see it on the **Management** tab under **Lifecycle rules**.

For information about CloudFormation templates and examples, see [Working with AWS CloudFormation templates](#) and [AWS::S3::Bucket](#) in the *AWS CloudFormation User Guide*.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Lifecycle configurations:

- `put-bucket-lifecycle-configuration`
- `get-bucket-lifecycle-configuration`
- `delete-bucket-lifecycle`

For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#).

The Amazon S3 Lifecycle configuration is an XML file. But when using the AWS CLI, you cannot specify the XML. You must specify the JSON instead. The following are example XML Lifecycle configurations and equivalent JSON that you can specify in an AWS CLI command.

Consider the following example S3 Lifecycle configuration.

Example Example 1

JSON

```
{  
    "Rules": [  
        {  
            "Filter": {  
                "Prefix": "documents/"  
            },  
            "Status": "Enabled",  
            "Transitions": [  
                {  
                    "Days": 365,  
                    "StorageClass": "GLACIER"  
                }  
            ],  
            "Expiration": {  
                "Days": 3650  
            },  
            "ID": "ExampleRule"  
        }  
    ]  
}
```

```
]  
}
```

XML

```
<LifecycleConfiguration>  
  <Rule>  
    <ID>ExampleRule</ID>  
    <Filter>  
      <Prefix>documents/</Prefix>  
    </Filter>  
    <Status>Enabled</Status>  
    <Transition>  
      <Days>365</Days>  
      <StorageClass>GLACIER</StorageClass>  
    </Transition>  
    <Expiration>  
      <Days>3650</Days>  
    </Expiration>  
  </Rule>  
</LifecycleConfiguration>
```

Example Example 2

JSON

```
{  
  "Rules": [  
    {  
      "ID": "id-1",  
      "Filter": {  
        "And": {  
          "Prefix": "myprefix",  
          "Tags": [  
            {  
              "Value": "mytagvalue1",  
              "Key": "mytagkey1"  
            },  
            {  
              "Value": "mytagvalue2",  
              "Key": "mytagkey2"  
            }  
          ]  
        }  
      }  
    }  
  ]  
}
```

```
        ]
    }
},
"Status": "Enabled",
"Expiration": {
    "Days": 1
}
}
]
```

XML

```
<LifecycleConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<Rule>
    <ID>id-1</ID>
    <Expiration>
        <Days>1</Days>
    </Expiration>
    <Filter>
        <And>
            <Prefix>myprefix</Prefix>
            <Tag>
                <Key>mytagkey1</Key>
                <Value>mytagvalue1</Value>
            </Tag>
            <Tag>
                <Key>mytagkey2</Key>
                <Value>mytagvalue2</Value>
            </Tag>
        </And>
    </Filter>
    <Status>Enabled</Status>
</Rule>
</LifecycleConfiguration>
```

You can test the put-bucket-lifecycle-configuration as follows.

To test the configuration

1. Save the JSON Lifecycle configuration in a file (`lifecycle.json`).
2. Run the following AWS CLI command to set the Lifecycle configuration on your bucket.

```
$ aws s3api put-bucket-lifecycle-configuration \
--bucket bucketname \
--lifecycle-configuration file://lifecycle.json
```

3. To verify, retrieve the S3 Lifecycle configuration using the get-bucket-lifecycle-configuration AWS CLI command as follows.

```
$ aws s3api get-bucket-lifecycle-configuration \
--bucket bucketname
```

4. To delete the S3 Lifecycle configuration use the delete-bucket-lifecycle AWS CLI command as follows.

```
aws s3api delete-bucket-lifecycle \
--bucket bucketname
```

Using the AWS SDKs

Java

You can use the AWS SDK for Java to manage the S3 Lifecycle configuration of a bucket. For more information about managing S3 Lifecycle configuration, see [Managing your storage lifecycle](#).

 **Note**

When you add S3 Lifecycle configuration to a bucket, Amazon S3 replaces the bucket's current Lifecycle configuration, if there is one. To update a configuration, you retrieve it, make the desired changes, and then add the revised configuration to the bucket.

The following example shows how to use the AWS SDK for Java to add, update, and delete the Lifecycle configuration of a bucket. The example does the following:

- Adds a Lifecycle configuration to a bucket.
- Retrieves the Lifecycle configuration and updates it by adding another rule.
- Adds the modified Lifecycle configuration to the bucket. Amazon S3 replaces the existing configuration.

- Retrieves the configuration again and verifies that it has the right number of rules by printing number of rules.
- Deletes the Lifecycle configuration and verifies that it has been deleted by attempting to retrieve it again.

For instructions on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

new
LifecycleTagPredicate(new Tag(
                    "expire_after",
                    "ten_years"))))))
                .withExpirationInDays(3650)

.withStatus(BucketLifecycleConfiguration.ENABLED));

        // Save the configuration.
s3Client.setBucketLifecycleConfiguration(bucketName,
configuration);

        // Retrieve the configuration.
configuration =
s3Client.getBucketLifecycleConfiguration(bucketName);

        // Verify that the configuration now has three rules.
configuration =
s3Client.getBucketLifecycleConfiguration(bucketName);
System.out.println("Expected # of rules = 3; found: " +
configuration.getRules().size());

        // Delete the configuration.
s3Client.deleteBucketLifecycleConfiguration(bucketName);

        // Verify that the configuration has been deleted by
attempting to retrieve it.
configuration =
s3Client.getBucketLifecycleConfiguration(bucketName);
String s = (configuration == null) ? "No configuration
found." : "Configuration found.";
System.out.println(s);
} catch (AmazonServiceException e) {
```

```
// The call was transmitted successfully, but Amazon S3
couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the
client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

.NET

You can use the AWS SDK for .NET to manage the S3 Lifecycle configuration on a bucket. For more information about managing Lifecycle configuration, see [Managing your storage lifecycle](#).

Note

When you add a Lifecycle configuration, Amazon S3 replaces the existing configuration on the specified bucket. To update a configuration, you must first retrieve the Lifecycle configuration, make the changes, and then add the revised Lifecycle configuration to the bucket.

The following example shows how to use the AWS SDK for .NET to add, update, and delete a bucket's Lifecycle configuration. The code example does the following:

- Adds a Lifecycle configuration to a bucket.
- Retrieves the Lifecycle configuration and updates it by adding another rule.
- Adds the modified Lifecycle configuration to the bucket. Amazon S3 replaces the existing Lifecycle configuration.
- Retrieves the configuration again and verifies it by printing the number of rules in the configuration.
- Deletes the Lifecycle configuration and verifies the deletion.

For instructions on how to create and test a working sample, see [Running the Amazon S3 .NET Code Examples](#).

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class LifecycleTest
    {
        private const string bucketName = "**** bucket name ****";
        // Specify your bucket region (an example region is shown).

Ruby

You can use the AWS SDK for Ruby to manage S3 Lifecycle configuration on a bucket by using the class [AWS::S3::BucketLifecycleConfiguration](#). For more information about using the AWS SDK for Ruby with Amazon S3, see [Using the AWS SDK for Ruby - Version 3](#). For more information about managing lifecycle configuration, see [Managing your storage lifecycle](#).

Using the REST API

The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API related to the S3 Lifecycle configuration.

- [PUT Bucket lifecycle](#)
- [GET Bucket lifecycle](#)
- [DELETE Bucket lifecycle](#)

Lifecycle and other bucket configurations

In addition to S3 Lifecycle configurations, you can associate other configurations with your bucket. This section explains how S3 Lifecycle configuration relates to other bucket configurations.

Lifecycle and versioning

You can add S3 Lifecycle configurations to unversioned buckets and versioning-enabled buckets. For more information, see [Using versioning in S3 buckets](#).

A versioning-enabled bucket maintains one current object version, and zero or more noncurrent object versions. You can define separate Lifecycle rules for current and noncurrent object versions.

For more information, see [Lifecycle configuration elements](#).

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets](#).

Lifecycle configuration on MFA-enabled buckets

Lifecycle configuration on multi-factor authentication (MFA)-enabled buckets is not supported.

Lifecycle and logging

Amazon S3 Lifecycle actions are not captured by AWS CloudTrail object level logging. CloudTrail captures API requests made to external Amazon S3 endpoints, whereas S3 Lifecycle actions are performed using internal Amazon S3 endpoints. Amazon S3 server access logs can be enabled in an S3 bucket to capture S3 Lifecycle-related actions such as object transition to another storage class and object expiration resulting in permanent deletion or logical deletion. For more information, see [the section called “Logging server access”](#).

If you have logging enabled on your bucket, Amazon S3 server access logs report the results of the following operations.

Operation log	Description
S3.EXPIRE.OBJECT	Amazon S3 permanently deletes the object due to the Lifecycle expiration action.
S3.CREATE.DELETEMARKER	Amazon S3 logically deletes the current version and adds a delete marker in a Versioning enabled bucket.
S3.TRANSITION_SIA.OBJECT	Amazon S3 transitions the object to the S3 Standard-IA storage class.

Operation log	Description
S3.TRANSITION_ZIA.OBJECT	Amazon S3 transitions the object to the S3 One Zone-IA storage class.
S3.TRANSITION_INT.OBJECT	Amazon S3 transitions the object to the S3 Intelligent-Tiering storage class.
S3.TRANSITION_GIR.OBJECT	Amazon S3 initiates the transition of object to the S3 Glacier Instant Retrieval storage class.
S3.TRANSITION.OBJECT	Amazon S3 initiates the transition of object to the S3 Glacier Flexible Retrieval storage class.
S3.TRANSITION_GDA.OBJECT	Amazon S3 initiates the transition of object to the S3 Glacier Deep Archive storage class.
S3.DELETE.UPLOAD	Amazon S3 aborts incomplete multipart upload.

 **Note**

Amazon S3 server access log records are generally delivered on a best-effort basis and cannot be used for complete accounting of all Amazon S3 requests.

Troubleshooting S3 Lifecycle

For more information about troubleshooting common issues with S3 Lifecycle, see [Troubleshoot Amazon S3 Lifecycle issues](#).

More info

- [Lifecycle configuration elements](#)
- [Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes \(object archival\)](#)
- [Setting lifecycle configuration on a bucket](#)

Configuring Lifecycle event notifications

You can set up an Amazon S3 event notification to receive notice when Amazon S3 deletes an object or transitions it to another Amazon S3 storage class following an S3 Lifecycle rule.

By using the *LifecycleExpiration* event types you can receive notifications whenever Amazon S3 deletes an object based on your S3 Lifecycle configuration. The `s3:LifecycleExpiration:Delete` event type notifies you when an object in an unversioned bucket is deleted. It also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration. The `s3:LifecycleExpiration:DeleteMarkerCreated` event type notifies you when S3 Lifecycle creates a delete marker when a current version of an object in versioned bucket is deleted. For more information, see [Delete object version](#).

By using the `s3:LifecycleTransition` event type, you can receive notification when an object is transitioned from one Amazon S3 storage class to another by an S3 Lifecycle configuration.

Amazon S3 can publish event notifications to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

For instructions on how to configure Amazon S3 Event Notifications, see [Enabling event notifications](#).

The following is an example of a message Amazon S3 sends to publish an `s3:LifecycleExpiration:Delete` event. For more information, see [Event message structure](#).

```
{
  "Records": [
    {
      "eventVersion": "2.3",
      "eventSource": "aws:s3",
      "awsRegion": "us-west-2",
      "eventTime": "1970-01-01T00:00:00.000Z",
      "eventName": "LifecycleExpiration:Delete",
      "userIdentity": {
        "principalId": "s3.amazonaws.com"
      },
      "requestParameters": {
        "sourceIPAddress": "s3.amazonaws.com"
      },
      "responseElements": {
        "x-amz-request-id": "C3D13FE58DE4C810"
      }
    }
  ]
}
```

```
"x-amz-id-2":"FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/
JRWeUWerMUE5JgHvANOjpd"
},
"s3": {
    "s3SchemaVersion": "1.0",
    "configurationId": "testConfigRule",
    "bucket": {
        "name": "mybucket",
        "ownerIdentity": {
            "principalId": "A3NL1K0ZZKExample"
        },
        "arn": "arn:aws:s3:::mybucket"
    },
    "object": {
        "key": "expiration/delete",
        "sequencer": "0055AED6DCD90281E5",
    }
}
]
```

Messages that Amazon S3 sends to publish an `s3:LifecycleTransition` event also includes the following information.

```
"lifecycleEventData": {
    "transitionEventData": {
        "destinationStorageClass": the destination storage class for the object
    }
}
```

Lifecycle configuration elements

Topics

- [ID element](#)
- [Status element](#)
- [Filter element](#)
- [Elements to describe lifecycle actions](#)

You specify an S3 Lifecycle configuration as XML, consisting of one or more Lifecycle rules.

```
<LifecycleConfiguration>
  <Rule>
    ...
  </Rule>
  <Rule>
    ...
  </Rule>
</LifecycleConfiguration>
```

Each rule consists of the following:

- Rule metadata that include a rule ID, and status indicating whether the rule is enabled or disabled. If a rule is disabled, Amazon S3 doesn't perform any actions specified in the rule.
- Filter identifying objects to which the rule applies. You can specify a filter by using object size, object key prefix, one or more object tags, or a combination of filters.
- One or more transition or expiration actions with a date or a time period in the object's lifetime when you want Amazon S3 to perform the specified action.

The following sections describe the XML elements in an S3 Lifecycle configuration. For example configurations, see [Examples of S3 Lifecycle configuration](#).

ID element

An S3 Lifecycle configuration can have up to 1,000 rules. This limit is not adjustable. The `<ID>` element uniquely identifies a rule. ID length is limited to 255 characters.

Status element

The `<Status>` element value can be either Enabled or Disabled. If a rule is disabled, Amazon S3 doesn't perform any of the actions defined in the rule.

Filter element

A Lifecycle rule can apply to all or a subset of objects in a bucket based on the `<Filter>` element that you specify in the Lifecycle rule.

You can filter objects by key prefix, object tags, or a combination of both (in which case Amazon S3 uses a logical AND to combine the filters). Consider the following examples:

- **Specifying a filter using key prefixes** – This example shows an S3 Lifecycle rule that applies to a subset of objects based on the key name prefix (logs/). For example, the Lifecycle rule applies to objects logs/mylog.txt, logs/temp1.txt, and logs/test.txt. The rule does not apply to the object example.jpg.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    transition/expiration actions.
    ...
  </Rule>
  ...
</LifecycleConfiguration>
```

If you want to apply a Lifecycle action to a subset of objects based on different key name prefixes, specify separate rules. In each rule, specify a prefix-based filter. For example, to describe a Lifecycle action for objects with key prefixes projectA/ and projectB/, you specify two rules as shown following.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Prefix>projectA/</Prefix>
    </Filter>
    transition/expiration actions.
    ...
  </Rule>

  <Rule>
    <Filter>
      <Prefix>projectB/</Prefix>
    </Filter>
    transition/expiration actions.
    ...
  </Rule>
</LifecycleConfiguration>
```

For more information about object keys, see [Creating object key names](#).

- **Specifying a filter based on object tags** – In the following example, the Lifecycle rule specifies a filter based on a tag (*key*) and value (*value*). The rule then applies only to a subset of objects with the specific tag.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Tag>
        <Key>key</Key>
        <Value>value</Value>
      </Tag>
    </Filter>
    transition/expiration actions.
    ...
  </Rule>
</LifecycleConfiguration>
```

You can specify a filter based on multiple tags. You must wrap the tags in the `<And>` element shown in the following example. The rule directs Amazon S3 to perform lifecycle actions on objects with two tags (with the specific tag key and value).

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Tag>
          <Key>key1</Key>
          <Value>value1</Value>
        </Tag>
        <Tag>
          <Key>key2</Key>
          <Value>value2</Value>
        </Tag>
        ...
      </And>
    </Filter>
    transition/expiration actions.
  </Rule>
</Lifecycle>
```

The Lifecycle rule applies to objects that have both of the tags specified. Amazon S3 performs a logical AND. Note the following:

- Each tag must match both key and value exactly.
- The rule applies to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule will still apply.

 **Note**

When you specify multiple tags in a filter, each tag key must be unique.

- **Specifying a filter based on both prefix and one or more tags** – In a Lifecycle rule, you can specify a filter based on both the key prefix and one or more tags. Again, you must wrap all of these in the <And> element as shown following.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Prefix>key-prefix</Prefix>
        <Tag>
          <Key>key1</Key>
          <Value>value1</Value>
        </Tag>
        <Tag>
          <Key>key2</Key>
          <Value>value2</Value>
        </Tag>
        ...
      </And>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions.
  </Rule>
</LifecycleConfiguration>
```

Amazon S3 combines these filters using a logical AND. That is, the rule applies to subset of objects with a specific key prefix and specific tags. A filter can have only one prefix, and zero or more tags.

- You can specify an **empty filter**, in which case the rule applies to all objects in the bucket.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      </Filter>
    <Status>Enabled</Status>
    transition/expiration actions.
  </Rule>
</LifecycleConfiguration>
```

- To filter a rule by **object size**, you can specify a minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLessThan`), or you can specify a range of object sizes.

Object size values are in bytes. Maximum filter size is 5TB. Some storage classes have minimum object size limitations, for more information, see [Comparing the Amazon S3 storage classes](#).

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <ObjectSizeGreater Than>500</ObjectSizeGreater Than>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions.
  </Rule>
</LifecycleConfiguration>
```

If you're specifying an object size range, the `ObjectSizeGreater Than` integer must be less than the `ObjectSizeLessThan` value. When using more than one filter, you must wrap the filters in an `<And>` element. The following example shows how to specify objects in a range between 500 and 64000 bytes.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Prefix>key-prefix</Prefix>
        <ObjectSizeGreater Than>500</ObjectSizeGreater Than>
        <ObjectSizeLessThan>64000</ObjectSizeLessThan>
      </And>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions.
  </Rule>
</LifecycleConfiguration>
```

```
</Rule>  
</LifecycleConfiguration>
```

Elements to describe lifecycle actions

You can direct Amazon S3 to perform specific actions in an object's lifetime by specifying one or more of the following predefined actions in an S3 Lifecycle rule. The effect of these actions depends on the versioning state of your bucket.

- **Transition action element** – You specify the Transition action to transition objects from one storage class to another. For more information about transitioning objects, see [Supported transitions and related constraints](#). When a specified date or time period in the object's lifetime is reached, Amazon S3 performs the transition.

For a versioned bucket (versioning-enabled or versioning-suspended bucket), the Transition action applies to the current object version. To manage noncurrent versions, Amazon S3 defines the NoncurrentVersionTransition action (described later in this topic).

- **Expiration action element** – The Expiration action expires objects identified in the rule and applies to eligible objects in any of the Amazon S3 storage classes. For more information about storage classes, see [Using Amazon S3 storage classes](#). Amazon S3 makes all expired objects unavailable. Whether the objects are permanently removed depends on the versioning state of the bucket.
 - **Non-versioned bucket** – The Expiration action results in Amazon S3 permanently removing the object.
 - **Versioned bucket** – For a versioned bucket (that is, versioning-enabled or versioning-suspended), there are several considerations that guide how Amazon S3 handles the Expiration action. For versioning-enabled or versioning-suspended buckets, the following applies:
 - The Expiration action applies only to the current version (it has no impact on noncurrent object versions).
 - Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
 - If the current object version is the only object version and it is also a delete marker (also referred as an *expired object delete marker*, where all object versions are deleted and you only have a delete marker remaining), Amazon S3 removes the expired object delete marker.

You can also use the expiration action to direct Amazon S3 to remove any expired object delete markers. For an example, see [Example 7: Removing expired object delete markers](#).

For more information, see [Using versioning in S3 buckets](#).

Also consider the following when setting up Amazon S3 to manage expiration:

- **Versioning-enabled bucket**

If the current object version is not a delete marker, Amazon S3 adds a delete marker with a unique version ID. This makes the current version noncurrent, and the delete marker the current version.

- **Versioning-suspended bucket**

In a versioning-suspended bucket, the expiration action causes Amazon S3 to create a delete marker with null as the version ID. This delete marker replaces any object version with a null version ID in the version hierarchy, which effectively deletes the object.

In addition, Amazon S3 provides the following actions that you can use to manage noncurrent object versions in a versioned bucket (that is, versioning-enabled and versioning-suspended buckets).

- **NoncurrentVersionTransition** action element – Use this action to specify when to have Amazon S3 transition objects to the specified storage class. You can base this expiration on a certain number of days since the objects become noncurrent. In addition to the number of days, you can also provide a maximum number of noncurrent versions to retain. This value determines how many newer noncurrent versions must exist before Amazon S3 can perform the associated action on a given version. You also need to provide a `Filter` element in order to specify the maximum number of noncurrent versions. If you do not specify a `Filter` element, Amazon S3 will generate an `InvalidRequest` error when you provide a maximum number of noncurrent versions.

For more information about transitioning objects, see [Supported transitions and related constraints](#). For details about how Amazon S3 calculates the date when you specify the number of days in the `NoncurrentVersionTransition` action, see [Lifecycle rules: Based on an object's age](#).

- **NoncurrentVersionExpiration** action element – Use this action to specify Amazon S3 to permanently delete noncurrent versions of objects. These deleted objects cannot be recovered.

You can base this expiration on a certain number of days since the objects become noncurrent. In addition to the number of days, you can also provide a maximum number of noncurrent versions to retain. This value specifies how many newer noncurrent versions must exist before Amazon S3 can perform the associated action on a given version. You also need to provide a `Filter` element in order to specify the maximum number of noncurrent versions. If you do not specify a `Filter` element, Amazon S3 will generate an `InvalidRequest` error when you provide a maximum number of noncurrent versions.

Delayed removal of noncurrent objects can be helpful when you need to correct any accidental deletes or overwrites. For example, you can configure an expiration rule to delete noncurrent versions five days after they become noncurrent. For example, suppose that on 1/1/2014 10:30 AM UTC, you create an object called `photo.gif` (version ID 111111). On 1/2/2014 11:30 AM UTC, you accidentally delete `photo.gif` (version ID 111111), which creates a delete marker with a new version ID (such as version ID 4857693). You now have five days to recover the original version of `photo.gif` (version ID 111111) before the deletion is permanent. On 1/8/2014 00:00 UTC, the Lifecycle rule for expiration executes and permanently deletes `photo.gif` (version ID 111111), five days after it became a noncurrent version.

For details about how Amazon S3 calculates the date when you specify the number of days in an `NoncurrentVersionExpiration` action, see [Lifecycle rules: Based on an object's age](#).

 **Note**

Object expiration lifecycle configurations do not remove incomplete multipart uploads. To remove incomplete multipart uploads, you must use the **AbortIncompleteMultipartUpload** Lifecycle configuration action that is described later in this section.

In addition to the transition and expiration actions, you can use the following Lifecycle configuration action to direct Amazon S3 to stop incomplete multipart uploads.

- **AbortIncompleteMultipartUpload** action element – Use this element to set a maximum time (in days) that you want to allow multipart uploads to remain in progress. If the applicable multipart uploads (determined by the key name prefix specified in the Lifecycle rule) are not successfully completed within the predefined time period, Amazon S3 stops the incomplete multipart uploads. For more information, see [Aborting a multipart upload](#).

Note

You cannot specify this Lifecycle action in a rule that specifies a filter based on object tags.

- **ExpiredObjectDeleteMarker** action element – In a versioning-enabled bucket, a delete marker with zero noncurrent versions is referred to as the expired object delete marker. You can use this Lifecycle action to direct S3 to remove the expired object delete markers. For an example, see [Example 7: Removing expired object delete markers](#).

Note

You cannot specify this Lifecycle action in a rule that specifies a filter based on object tags.

How Amazon S3 calculates how long an object has been noncurrent

In a versioning-enabled bucket, you can have multiple versions of an object. There is always one current version, and zero or more noncurrent versions. Each time you upload an object, the current version is retained as the noncurrent version and the newly added version, the successor, becomes the current version. To determine the number of days an object is noncurrent, Amazon S3 looks at when its successor was created. Amazon S3 uses the number of days since its successor was created as the number of days an object is noncurrent.

Note Restoring previous versions of an object when using S3 Lifecycle configurations

As explained in detail in the topic [Restoring previous versions](#), you can use either of the following two methods to retrieve previous versions of an object:

1. By copying a noncurrent version of the object into the same bucket. The copied object becomes the current version of that object, and all object versions are preserved.
2. By permanently deleting the current version of the object. When you delete the current object version, you, in effect, turn the noncurrent version into the current version of that object.

When you are using S3 Lifecycle configuration rules with versioning-enabled buckets, we recommend as a best practice that you use the first method.

S3 Lifecycle operates under an eventually consistent model. A current version that you permanently deleted might not disappear until the changes propagate (Amazon S3 might be unaware of this deletion). In the meantime, the lifecycle rule that you configured to expire noncurrent objects might permanently remove noncurrent objects, including the one that you want to restore. So, copying the old version, as recommended in the first method, is the safer alternative.

Lifecycle rules: Based on an object's age

You can specify a time period, in number of days from the creation (or modification) of the objects, when Amazon S3 can take the action.

When you specify the number of days in the Transition and Expiration actions in an S3 Lifecycle configuration, note the following:

- It is the number of days since object creation when the action will occur.
- Amazon S3 calculates the time by adding the number of days specified in the rule to the object creation time and rounding the resulting time to the next day midnight UTC. For example, if an object was created at 1/15/2014 10:30 AM UTC and you specify 3 days in a transition rule, then the transition date of the object would be calculated as 1/19/2014 00:00 UTC.

Note

Amazon S3 maintains only the last modified date for each object. For example, the Amazon S3 console shows the **Last Modified** date in the object **Properties** pane. When you initially create a new object, this date reflects the date the object is created. If you replace the object, the date changes accordingly. So when we use the term *creation date*, it is synonymous with the term *last modified date*.

When specifying the number of days in the NoncurrentVersionTransition and NoncurrentVersionExpiration actions in a Lifecycle configuration, note the following:

- It is the number of days from when the version of the object becomes noncurrent (that is, when the object is overwritten or deleted) that Amazon S3 will perform the action on the specified object or objects.
- Amazon S3 calculates the time by adding the number of days specified in the rule to the time when the new successor version of the object is created and rounding the resulting time to the next day midnight UTC. For example, in your bucket, suppose that you have a current version of an object that was created at 1/1/2014 10:30 AM UTC. If the new version of the object that replaces the current version is created at 1/15/2014 10:30 AM UTC, and you specify 3 days in a transition rule, the transition date of the object is calculated as 1/19/2014 00:00 UTC.

Lifecycle rules: Based on a specific date

When specifying an action in an S3 Lifecycle rule, you can specify a date when you want Amazon S3 to take the action. When the specific date arrives, Amazon S3 applies the action to all qualified objects (based on the filter criteria).

If you specify an S3 Lifecycle action with a date that is in the past, all qualified objects become immediately eligible for that Lifecycle action.

Important

The date-based action is not a one-time action. Amazon S3 continues to apply the date-based action even after the date has passed, as long as the rule status is Enabled.

For example, suppose that you specify a date-based `Expiration` action to delete all objects (assume no filter specified in the rule). On the specified date, Amazon S3 expires all the objects in the bucket. S3 also continues to expire any new objects you create in the bucket. To stop the Lifecycle action, you must remove the action from the Lifecycle configuration, disable the rule, or delete the rule from the Lifecycle configuration.

The date value must conform to the ISO 8601 format. The time is always midnight UTC.

Note

You can't create the date-based Lifecycle rules using the Amazon S3 console, but you can view, disable, or delete such rules.

Examples of S3 Lifecycle configuration

This section provides examples of S3 Lifecycle configuration. Each example shows how you can specify the XML in each of the example scenarios.

Topics

- [Example 1: Specifying a filter](#)
- [Example 2: Disabling a Lifecycle rule](#)
- [Example 3: Tiering down storage class over an object's lifetime](#)
- [Example 4: Specifying multiple rules](#)
- [Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets](#)
- [Example 6: Specifying a lifecycle rule for a versioning-enabled bucket](#)
- [Example 7: Removing expired object delete markers](#)
- [Example 8: Lifecycle configuration to abort multipart uploads](#)
- [Example 9: Lifecycle configuration using size-based rules](#)

Example 1: Specifying a filter

Each S3 Lifecycle rule includes a filter that you can use to identify a subset of objects in your bucket to which the S3 Lifecycle rule applies. The following S3 Lifecycle configurations show examples of how you can specify a filter.

- In this S3 Lifecycle configuration rule, the filter specifies a key prefix (tax/). Therefore, the rule applies to objects with the key name prefix tax/, such as tax/doc1.txt and tax/doc2.txt.

The rule specifies two actions that direct Amazon S3 to do the following:

- Transition objects to the S3 Glacier Flexible Retrieval storage class 365 days (one year) after creation.
- Delete objects (the **Expiration** action) 3,650 days (10 years) after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition and Expiration Rule</ID>
    <Filter>
      <Prefix>tax/</Prefix>
```

```
</Filter>
<Status>Enabled</Status>
<Transition>
  <Days>365</Days>
  <StorageClass>S3 Glacier Flexible Retrieval</StorageClass>
</Transition>
<Expiration>
  <Days>3650</Days>
</Expiration>
</Rule>
</LifecycleConfiguration>
```

Instead of specifying object age in terms of days after creation, you can specify a date for each action. However, you can't use both Date and Days in the same rule.

- If you want the S3 Lifecycle rule to apply to all objects in the bucket, specify an empty prefix. In the following configuration, the rule specifies a Transition action that directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 0 days after creation. This rule means that the objects are eligible for archival to Amazon S3 Glacier at midnight UTC following creation. For more information about lifecycle constraints, see [Constraints](#).

```
<LifecycleConfiguration>
<Rule>
  <ID>Archive all object same-day upon creation</ID>
  <Filter>
    <Prefix></Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <Days>0</Days>
    <StorageClass>S3 Glacier Flexible Retrieval</StorageClass>
  </Transition>
</Rule>
</LifecycleConfiguration>
```

- You can specify zero or one key name prefix and zero or more object tags in a filter. The following example code applies the S3 Lifecycle rule to a subset of objects with the tax/ key prefix and to objects that have two tags with specific key and value. When you specify more than one filter, you must include the <And> element as shown (Amazon S3 applies a logical AND to combine the specified filter conditions).

...

```
<Filter>
  <And>
    <Prefix>tax/</Prefix>
    <Tag>
      <Key>key1</Key>
      <Value>value1</Value>
    </Tag>
    <Tag>
      <Key>key2</Key>
      <Value>value2</Value>
    </Tag>
  </And>
</Filter>
...
...
```

- You can filter objects based only on tags. For example, the following S3 Lifecycle rule applies to objects that have the two specified tags (it does not specify any prefix).

```
...
<Filter>
  <And>
    <Tag>
      <Key>key1</Key>
      <Value>value1</Value>
    </Tag>
    <Tag>
      <Key>key2</Key>
      <Value>value2</Value>
    </Tag>
  </And>
</Filter>
...
...
```

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.

- Transition takes precedence over creation of delete markers.
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets](#).

Example 2: Disabling a Lifecycle rule

You can temporarily disable a S3 Lifecycle rule. The following S3 Lifecycle configuration specifies two rules:

- Rule 1 directs Amazon S3 to transition objects with the logs/ prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.
- Rule 2 directs Amazon S3 to transition objects with the documents/ prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.

In the configuration, Rule 1 is enabled and Rule 2 is disabled. Amazon S3 ignores disabled rules.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>S3 Glacier Flexible Retrieval</StorageClass>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule2</ID>
    <Filter>
      <Prefix>documents/</Prefix>
    </Filter>
```

```
<Status>Disabled</Status>
<Transition>
  <Days>0</Days>
  <StorageClass>S3 Glacier Flexible Retrieval</StorageClass>
</Transition>
</Rule>
</LifecycleConfiguration>
```

Example 3: Tiering down storage class over an object's lifetime

In this example, you use S3 Lifecycle configuration to tier down the storage class of objects over their lifetime. Tiering down can help reduce storage costs. For more information about pricing, see [Amazon S3 pricing](#).

The following S3 Lifecycle configuration specifies a rule that applies to objects with the key name prefix logs/. The rule specifies the following actions:

- Two transition actions:
 - Transition objects to the S3 Standard-IA storage class 30 days after creation.
 - Transition objects to the S3 Glacier Flexible Retrieval storage class 90 days after creation.
- One expiration action that directs Amazon S3 to delete objects a year after creation.

```
<LifecycleConfiguration>
<Rule>
  <ID>example-id</ID>
  <Filter>
    <Prefix>logs/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <Days>30</Days>
    <StorageClass>STANDARD_IA</StorageClass>
  </Transition>
  <Transition>
    <Days>90</Days>
    <StorageClass>GLACIER</StorageClass>
  </Transition>
  <Expiration>
    <Days>365</Days>
  </Expiration>
</Rule>
```

```
</LifecycleConfiguration>
```

Note

You can use one rule to describe all S3 Lifecycle actions if all actions apply to the same set of objects (identified by the filter). Otherwise, you can add multiple rules with each specifying a different filter.

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets](#).

Example 4: Specifying multiple rules

You can specify multiple rules if you want different S3 Lifecycle actions of different objects. The following S3 Lifecycle configuration has two rules:

- Rule 1 applies to objects with the key name prefix `classA/`. It directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class one year after creation and expire these objects 10 years after creation.
- Rule 2 applies to objects with key name prefix `classB/`. It directs Amazon S3 to transition objects to the S3 Standard-IA storage class 90 days after creation and delete them one year after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>ClassADocRule</ID>
    <Filter>
      <Prefix>classA/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
    <Expiration>
      <Days>3650</Days>
    </Expiration>
  </Rule>
  <Rule>
    <ID>ClassBDocRule</ID>
    <Filter>
      <Prefix>classB/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>90</Days>
      <StorageClass>STANDARD_IA</StorageClass>
    </Transition>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.

- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets](#).

Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets

You might specify an S3 Lifecycle configuration in which you specify overlapping prefixes, or actions.

Generally, S3 Lifecycle optimizes for cost. For example, if two expiration policies overlap, the shorter expiration policy is honored so that data is not stored for longer than expected. Likewise, if two transition policies overlap, S3 Lifecycle transitions your objects to the lower-cost storage class.

In both cases, S3 Lifecycle tries to choose the path that is least expensive for you. An exception to this general rule is with the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is favored by S3 Lifecycle over any storage class, aside from the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.

The following examples show how Amazon S3 resolves potential conflicts.

Example 1: Overlapping prefixes (no conflict)

The following example configuration has two rules that specify overlapping prefixes as follows:

- The first rule specifies an empty filter, indicating all objects in the bucket.
- The second rule specifies a key name prefix (logs/), indicating only a subset of objects.

Rule 1 requests Amazon S3 to delete all objects one year after creation. Rule 2 requests Amazon S3 to transition a subset of objects to the S3 Standard-IA storage class 30 days after creation.

```
<LifecycleConfiguration>
  <Rule>
```

```
<ID>Rule 1</ID>
<Filter>
</Filter>
<Status>Enabled</Status>
<Expiration>
  <Days>365</Days>
</Expiration>
</Rule>
<Rule>
  <ID>Rule 2</ID>
  <Filter>
    <Prefix>logs/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <StorageClass>STANDARD_IA<StorageClass>
    <Days>30</Days>
  </Transition>
</Rule>
</LifecycleConfiguration>
```

Since there is no conflict in this case, Amazon S3 will transition the objects with the logs/ prefix to the S3 Standard-IA storage class 30 days after creation. When any object reaches one year after creation, it will be deleted.

Example 2: Conflicting lifecycle actions

In this example configuration, there are two rules that direct Amazon S3 to perform two different actions on the same set of objects at the same time in the objects' lifetime:

- Both rules specify the same key name prefix, so both rules apply to the same set of objects.
- Both rules specify the same 365 days after object creation when the rules apply.
- One rule directs Amazon S3 to transition objects to the S3 Standard-IA storage class and another rule wants Amazon S3 to expire the objects at the same time.

```
<LifecycleConfiguration>
<Rule>
  <ID>Rule 1</ID>
  <Filter>
    <Prefix>logs/</Prefix>
  </Filter>
```

```
<Status>Enabled</Status>
<Expiration>
  <Days>365</Days>
</Expiration>
</Rule>
<Rule>
  <ID>Rule 2</ID>
  <Filter>
    <Prefix>logs/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <StorageClass>STANDARD_IA<StorageClass>
    <Days>365</Days>
  </Transition>
</Rule>
</LifecycleConfiguration>
```

In this case, because you want objects to expire (to be removed), there is no point in changing the storage class, so Amazon S3 chooses the expiration action on these objects.

Example 3: Overlapping prefixes resulting in conflicting lifecycle actions

In this example, the configuration has two rules, which specify overlapping prefixes as follows:

- Rule 1 specifies an empty prefix (indicating all objects).
- Rule 2 specifies a key name prefix (logs/) that identifies a subset of all objects.

For the subset of objects with the logs/ key name prefix, S3 Lifecycle actions in both rules apply. One rule directs Amazon S3 to transition objects 10 days after creation, and another rule directs Amazon S3 to transition objects 365 days after creation.

```
<LifecycleConfiguration>
<Rule>
  <ID>Rule 1</ID>
  <Filter>
    <Prefix></Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <StorageClass>STANDARD_IA<StorageClass>
```

```
<Days>10</Days>
</Transition>
</Rule>
<Rule>
<ID>Rule 2</ID>
<Filter>
<Prefix>logs/</Prefix>
</Filter>
<Status>Enabled</Status>
<Transition>
<StorageClass>STANDARD_IA<StorageClass>
<Days>365</Days>
</Transition>
</Rule>
</LifecycleConfiguration>
```

In this case, Amazon S3 chooses to transition them 10 days after creation.

Example 4: Tag-based filtering and resulting conflicting lifecycle actions

Suppose that you have the following S3 Lifecycle configuration that has two rules, each specifying a tag filter:

- Rule 1 specifies a tag-based filter (tag1/value1). This rule directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 365 days after creation.
- Rule 2 specifies a tag-based filter (tag2/value2). This rule directs Amazon S3 to expire objects 14 days after creation.

The S3 Lifecycle configuration is shown in following example.

```
<LifecycleConfiguration>
<Rule>
<ID>Rule 1</ID>
<Filter>
<Tag>
<Key>tag1</Key>
<Value>value1</Value>
</Tag>
</Filter>
<Status>Enabled</Status>
<Transition>
```

```
<StorageClass>GLACIER</StorageClass>
<Days>365</Days>
</Transition>
</Rule>
<Rule>
<ID>Rule 2</ID>
<Filter>
<Tag>
<Key>tag2</Key>
<Value>value2</Value>
</Tag>
</Filter>
<Status>Enabled</Status>
<Expiration>
<Days>14</Days>
</Expiration>
</Rule>
</LifecycleConfiguration>
```

If an object has both tags, then Amazon S3 has to decide which rule to follow. In this case, Amazon S3 expires the object 14 days after creation. The object is removed, and therefore the transition action does not apply.

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Example 5: Overlapping filters, conflicting lifecycle actions, and what Amazon S3 does with nonversioned buckets](#).

Example 6: Specifying a lifecycle rule for a versioning-enabled bucket

Suppose that you have a versioning-enabled bucket, which means that for each object, you have a current version and zero or more noncurrent versions. (For more information about S3 Versioning, see [Using versioning in S3 buckets](#).) In this example, you want to maintain one year's worth of history, and delete the noncurrent versions. S3 Lifecycle configurations supports keeping 1 to 100 versions of any object.

To save storage costs, you want to move noncurrent versions to S3 Glacier Flexible Retrieval 30 days after they become noncurrent (assuming that these noncurrent objects are cold data for which you don't need real-time access). In addition, you expect frequency of access of the current versions to diminish 90 days after creation, so you might choose to move these objects to the S3 Standard-IA storage class.

```
<LifecycleConfiguration>
  <Rule>
    <ID>sample-rule</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>90</Days>
      <StorageClass>STANDARD_IA</StorageClass>
    </Transition>
    <NoncurrentVersionTransition>
      <NoncurrentDays>30</NoncurrentDays>
      <StorageClass>S3 Glacier Flexible Retrieval</StorageClass>
    </NoncurrentVersionTransition>
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>5</NewerNoncurrentVersions>
      <NoncurrentDays>365</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

Example 7: Removing expired object delete markers

A versioning-enabled bucket has one current version and zero or more noncurrent versions for each object. When you delete an object, note the following:

- If you don't specify a version ID in your delete request, Amazon S3 adds a delete marker instead of deleting the object. The current object version becomes noncurrent, and the delete marker becomes the current version.
- If you specify a version ID in your delete request, Amazon S3 deletes the object version permanently (a delete marker is not created).
- A delete marker with zero noncurrent versions is referred to as an *expired object delete marker*.

This example shows a scenario that can create expired object delete markers in your bucket, and how you can use S3 Lifecycle configuration to direct Amazon S3 to remove the expired object delete markers.

Suppose that you write a S3 Lifecycle configuration that uses the NoncurrentVersionExpiration action to remove the noncurrent versions 30 days after they become noncurrent and retains at most 10 noncurrent versions, as shown in the following example.

```
<LifecycleConfiguration>
  <Rule>
    ...
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

The NoncurrentVersionExpiration action does not apply to the current object versions. It removes only the noncurrent versions.

For current object versions, you have the following options to manage their lifetime, depending on whether the current object versions follow a well-defined lifecycle:

- **The current object versions follow a well-defined lifecycle.**

In this case, you can use an S3 Lifecycle configuration with the Expiration action to direct Amazon S3 to remove the current versions, as shown in the following example.

```
<LifecycleConfiguration>
  <Rule>
    ...
  </Rule>
```

```
<Expiration>
  <Days>60</Days>
</Expiration>
<NoncurrentVersionExpiration>
  <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
  <NoncurrentDays>30</NoncurrentDays>
</NoncurrentVersionExpiration>
</Rule>
</LifecycleConfiguration>
```

In this example, Amazon S3 removes current versions 60 days after they are created by adding a delete marker for each of the current object versions. This process makes the current version noncurrent, and the delete marker becomes the current version. For more information, see [Using versioning in S3 buckets](#).

 **Note**

You cannot specify both a Days and an `ExpiredObjectDeleteMarker` tag on the same rule. When you specify the Days tag, Amazon S3 automatically performs `ExpiredObjectDeleteMarker` cleanup when the delete markers are old enough to satisfy the age criteria. To clean up delete markers as soon as they become the only version, create a separate rule with only the `ExpiredObjectDeleteMarker` tag.

The `NoncurrentVersionExpiration` action in the same S3 Lifecycle configuration removes noncurrent objects 30 days after they become noncurrent. Thus, in this example, all object versions are permanently removed 90 days after object creation. Although expired object delete markers are created during this process, Amazon S3 detects and removes the expired object delete markers for you.

- **The current object versions don't have a well-defined lifecycle.**

In this case, you might remove the objects manually when you don't need them, creating a delete marker with one or more noncurrent versions. If your S3 Lifecycle configuration with the `NoncurrentVersionExpiration` action removes all the noncurrent versions, you now have expired object delete markers.

Specifically for this scenario, S3 Lifecycle configuration provides an `Expiration` action that you can use to remove the expired object delete markers.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <ExpiredObjectDeleteMarker>true</ExpiredObjectDeleteMarker>
    </Expiration>
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

By setting the `ExpiredObjectDeleteMarker` element to `true` in the `Expiration` action, you direct Amazon S3 to remove the expired object delete markers.

 **Note**

When you use the `ExpiredObjectDeleteMarker` S3 Lifecycle action, the rule cannot specify a tag-based filter.

Example 8: Lifecycle configuration to abort multipart uploads

You can use the Amazon S3 multipart upload REST API operations to upload large objects in parts. For more information about multipart uploads, see [Uploading and copying objects using multipart upload](#).

Using S3 Lifecycle configuration, you can direct Amazon S3 to stop incomplete multipart uploads (identified by the key name prefix specified in the rule) if they aren't completed within a specified number of days after initiation. When Amazon S3 aborts a multipart upload, it deletes all the parts associated with the multipart upload. This process helps control your storage costs by ensuring that you don't have incomplete multipart uploads with parts that are stored in Amazon S3.

Note

When you use the AbortIncompleteMultipartUpload S3 Lifecycle action, the rule cannot specify a tag-based filter.

The following is an example S3 Lifecycle configuration that specifies a rule with the AbortIncompleteMultipartUpload action. This action directs Amazon S3 to stop incomplete multipart uploads seven days after initiation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>sample-rule</ID>
    <Filter>
      <Prefix>SomeKeyPrefix</Prefix>
    </Filter>
    <Status>rule-status</Status>
    <AbortIncompleteMultipartUpload>
      <DaysAfterInitiation>7</DaysAfterInitiation>
    </AbortIncompleteMultipartUpload>
  </Rule>
</LifecycleConfiguration>
```

Example 9: Lifecycle configuration using size-based rules

You can create rules that transition objects based only on their size. You can specify a minimum size (ObjectSizeGreater Than) or a maximum size (ObjectSizeLess Than), or you can specify a range of object sizes in bytes. When using more than one filter, such as a prefix and size rule, you must wrap the filters in an <And> element.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition with a prefix and based on size</ID>
    <Filter>
      <And>
        <Prefix>tax/</Prefix>
        <ObjectSizeGreater Than>500</ObjectSizeGreater Than>
      </And>
    </Filter>
    <Status>Enabled</Status>
  </Rule>
</LifecycleConfiguration>
```

```
<Transition>
  <Days>365</Days>
  <StorageClass>S3 Glacier Flexible Retrieval</StorageClass>
</Transition>
</Rule>
</LifecycleConfiguration>
```

If you're specifying a range by using both the `ObjectSizeGreaterThanOrEqual` and `ObjectSizeLessThan` elements, the maximum object size must be larger than the minimum object size. When using more than one filter, you must wrap the filters in an `<And>` element. The following example shows how to specify objects in a range between 500 and 64000 bytes.

```
<LifecycleConfiguration>
  <Rule>
    ...
    <And>
      <ObjectSizeGreaterThanOrEqual>500</ObjectSizeGreaterThanOrEqual>
      <ObjectSizeLessThan>64000</ObjectSizeLessThan>
    </And>
  </Rule>
</LifecycleConfiguration>
```

You can also create rules to specifically expire noncurrent objects that have no data, including noncurrent delete marker objects created in a versioning-enabled bucket. The following example uses the `NoncurrentVersionExpiration` action to remove noncurrent versions 30 days after they become noncurrent and retain at most 10 noncurrent versions of objects. It also uses the `ObjectSizeLessThan` element to filter only objects with no data.

```
<LifecycleConfiguration>

Amazon S3 Inventory

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

You can use Amazon S3 Inventory to help manage your storage. For example, you can use it to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also simplify and speed up business workflows and big data jobs by using Amazon S3 Inventory, which provides a scheduled alternative to the Amazon S3 synchronous List API operations. Amazon S3 Inventory does not use the List API operations to audit your objects and does not affect the request rate of your bucket.

Amazon S3 Inventory provides comma-separated values (CSV), [Apache optimized row columnar \(ORC\)](#) or [Apache Parquet](#) output files that list your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or objects with a shared prefix (that is, objects that have names that begin with a common string). If you set up a weekly inventory, a report is generated every Sunday (UTC time zone) after the initial report. For information about Amazon S3 Inventory pricing, see [Amazon S3 pricing](#).

You can configure multiple inventory lists for a bucket. When you're configuring an inventory list, you can specify the following:

- What object metadata to include in the inventory
- Whether to list all object versions or only current versions
- Where to store the inventory list file output
- Whether to generate the inventory on a daily or weekly basis
- Whether to encrypt the inventory list file

You can query Amazon S3 Inventory with standard SQL queries by using [Amazon Athena](#), [Amazon Redshift Spectrum](#), and other tools, such as [Presto](#), [Apache Hive](#), and [Apache Spark](#). For more information about using Athena to query your inventory files, see [the section called “Querying inventory with Athena”](#).

Source and destination buckets

The bucket that the inventory lists objects for is called the *source bucket*. The bucket where the inventory list file is stored is called the *destination bucket*.

Source bucket

The inventory lists the objects that are stored in the source bucket. You can get an inventory list for an entire bucket, or you can filter the list by object key name prefix.

The source bucket:

- Contains the objects that are listed in the inventory
- Contains the configuration for the inventory

Destination bucket

Amazon S3 Inventory list files are written to the destination bucket. To group all the inventory list files in a common location in the destination bucket, you can specify a destination prefix in the inventory configuration.

The destination bucket:

- Contains the inventory file lists.
- Contains the manifest files that list all the inventory list files that are stored in the destination bucket. For more information, see [Inventory manifest](#).
- Must have a bucket policy to give Amazon S3 permission to verify ownership of the bucket and permission to write files to the bucket.
- Must be in the same AWS Region as the source bucket.
- Can be the same as the source bucket.
- Can be owned by a different AWS account than the account that owns the source bucket.

Amazon S3 Inventory list

An inventory list file contains a list of the objects in the source bucket and metadata for each object. An inventory list file is stored in the destination bucket with one of the following formats:

- As a CSV file compressed with GZIP
- As an Apache optimized row columnar (ORC) file compressed with ZLIB
- As an Apache Parquet file compressed with Snappy

 **Note**

Objects in Amazon S3 Inventory reports aren't guaranteed to be sorted in any order.

An inventory list file contains a list of the objects in the source bucket and metadata for each listed object:

- **Bucket name** – The name of the bucket that the inventory is for.
- **Key name** – The object key name (or key) that uniquely identifies the object in the bucket. When you're using the CSV file format, the key name is URL-encoded and must be decoded before you can use it.
- **Version ID** – The object version ID. When you enable versioning on a bucket, Amazon S3 assigns a version number to objects that are added to the bucket. For more information, see [Using versioning in S3 buckets](#). (This field is not included if the list is configured only for the current version of the objects.)
- **IsLatest** – Set to True if the object is the current version of the object. (This field is not included if the list is configured only for the current version of the objects.)
- **Delete marker** – Set to True if the object is a delete marker. For more information, see [Using versioning in S3 buckets](#). (This field is automatically added to your report if you've configured the report to include all versions of your objects).
- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.

- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag can be an MD5 digest of the object data. Whether it depends on how the object was created and how it is encrypted.
- **Storage class** – The storage class that's used for storing the object. Set to STANDARD, REDUCED_REDUNDANCY, STANDARD_IA, ONEZONE_IA, INTELLIGENT_TIERING, GLACIER, DEEP_ARCHIVE, OUTPOSTS, GLACIER_IR, or SNOW. For more information, see [Using Amazon S3 storage classes](#).
- **Multipart upload flag** – Set to True if the object was uploaded as a multipart upload. For more information, see [Uploading and copying objects using multipart upload](#).
- **Replication status** – Set to PENDING, COMPLETED, FAILED, or REPLICA. For more information, see [Getting replication status information](#).
- **Encryption status** – The server-side encryption status, depending on what kind of encryption key is used—an Amazon S3 managed (SSE-S3) key, an AWS Key Management Service (AWS KMS) key (SSE-KMS), or a customer-provided key (SSE-C). Set to SSE-S3, SSE-C, SSE-KMS, or NOT-SSE. A status of NOT-SSE means that the object is not encrypted with server-side encryption. For more information, see [Protecting data with encryption](#).
- **S3 Object Lock retain until date** – The date until which the locked object cannot be deleted. For more information, see [Using S3 Object Lock](#).
- **S3 Object Lock retention mode** – Set to Governance or Compliance for objects that are locked. For more information, see [Using S3 Object Lock](#).
- **S3 Object Lock legal hold status** – Set to On if a legal hold has been applied to an object. Otherwise, it is set to Off. For more information, see [Using S3 Object Lock](#).
- **S3 Intelligent-Tiering access tier** – Access tier (frequent or infrequent) of the object if it is stored in the S3 Intelligent-Tiering storage class. Set to FREQUENT, INFREQUENT, ARCHIVE_INSTANT_ACCESS, ARCHIVE, or DEEP_ARCHIVE. For more information, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).
- **S3 Bucket Key status** – Set to ENABLED or DISABLED. Indicates whether the object uses an S3 Bucket Key for SSE-KMS. For more information, see [Using Amazon S3 Bucket Keys](#).
- **Checksum algorithm** – Indicates the algorithm that's used to create the checksum for the object.
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. The Object ACL field is defined in JSON format. An S3 Inventory report includes ACLs that are associated with objects in your source bucket, even when ACLs are disabled for the bucket. For more information, see [Working with the Object ACL field](#) and [Access control list \(ACL\) overview](#).

Note

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.

For example, suppose that you have the following Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {"canonicalId": "example-canonical-user-ID",  
         "type": "CanonicalUser",  
         "permission": "READ"  
     }]  
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQU1MQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2Fs
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see [Querying Amazon S3 Inventory with Amazon Athena](#).

- **Object owner** – The owner of the object.

Note

When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. The inventory report includes the objects that have expired but haven't been removed yet. For more information about expiration actions in S3 Lifecycle, see [Expiring objects](#).

We recommend that you create a lifecycle policy that deletes old inventory lists. For more information, see [Managing your storage lifecycle](#).

The `s3:PutInventoryConfiguration` permission allows a user to both select all the metadata fields that are listed earlier for each object when configuring an inventory list and to specify the destination bucket to store the inventory. A user with read access to objects in the destination bucket can access all object metadata fields that are available in the inventory list. To restrict access to an inventory report, see [Grant permissions for S3 Inventory and S3 analytics](#).

Inventory consistency

All of your objects might not appear in each inventory list. The inventory list provides eventual consistency for PUT requests (of both new objects and overwrites) and for DELETE requests. Each inventory list for a bucket is a snapshot of bucket items. These lists are eventually consistent (that is, a list might not include recently added or deleted objects).

To validate the state of an object before you take action on the object, we recommend that you perform a `HeadObject` REST API request to retrieve metadata for the object, or to check the object's properties in the Amazon S3 console. You can also check object metadata with the AWS CLI or the AWS SDKs. For more information, see [HeadObject](#) in the *Amazon Simple Storage Service API Reference*.

For more information about working with Amazon S3 Inventory, see the following topics.

- [Working with the Object ACL field](#)

Configuring Amazon S3 Inventory

Amazon S3 Inventory provides a flat file list of your objects and metadata, on a schedule that you define. You can use S3 Inventory as a scheduled alternative to the Amazon S3 synchronous `List` API operation. S3 Inventory provides comma-separated values (CSV), [Apache optimized row columnar \(ORC\)](#), or [Apache Parquet \(Parquet\)](#) output files that list your objects and their corresponding metadata. You can configure S3 Inventory to create inventory lists on a daily or

weekly basis for an S3 bucket or for objects that share a prefix (objects that have names that begin with the same string). For more information, see [Amazon S3 Inventory](#).

This section describes how to configure an inventory, including details about the inventory source and destination buckets.

Topics

- [Overview](#)
- [Creating a destination bucket policy](#)
- [Granting Amazon S3 permission to use your customer managed key for encryption](#)
- [Configuring inventory by using the S3 console](#)
- [Using the REST API to work with S3 Inventory](#)

Overview

Amazon S3 Inventory helps you manage your storage by creating lists of the objects in an S3 bucket on a defined schedule. You can configure multiple inventory lists for a bucket. The inventory lists are published to CSV, ORC, or Parquet files in a destination bucket.

The easiest way to set up an inventory is by using the AWS Management Console, but you can also use the REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs. The console performs the first step of the following procedure for you: adding a bucket policy to the destination bucket.

To set up Amazon S3 Inventory for an S3 bucket

1. Add a bucket policy for the destination bucket.

You must create a bucket policy on the destination bucket to grant permissions to Amazon S3 to write objects to the bucket in the defined location. For an example policy, see [Grant permissions for S3 Inventory and S3 analytics](#).

2. Configure an inventory to list the objects in a source bucket and publish the list to a destination bucket.

When you configure an inventory list for a source bucket, you specify the destination bucket where you want the list to be stored, and whether you want to generate the list daily or weekly. You can also configure what object metadata to include and whether to list all object versions or only current versions.

You can specify that the inventory list file be encrypted by using server-side encryption with an Amazon S3 managed key (SSE-S3) or an AWS Key Management Service (AWS KMS) customer managed key (SSE-KMS).

 **Note**

The AWS managed key (aws/s3) is not supported for SSE-KMS encryption with S3 Inventory.

For more information about SSE-S3 and SSE-KMS, see [Protecting data with server-side encryption](#). If you plan to use SSE-KMS encryption, see Step 3.

- For information about how to use the console to configure an inventory list, see [Configuring inventory by using the S3 console](#).
- To use the Amazon S3 API to configure an inventory list, use the [PutBucketInventoryConfiguration](#) REST API operation or the equivalent from the AWS CLI or AWS SDKs.

3. To encrypt the inventory list file with SSE-KMS, grant Amazon S3 permission to use the AWS KMS key.

You can configure encryption for the inventory list file by using the AWS Management Console, REST API, AWS CLI, or AWS SDKs. Whichever way you choose, you must grant Amazon S3 permission to use the customer managed key to encrypt the inventory file. You grant Amazon S3 permission by modifying the key policy for the customer managed key that you want to use to encrypt the inventory file. For more information, see [Granting Amazon S3 permission to use your customer managed key for encryption](#).

The destination bucket that stores the inventory list file can be owned by a different AWS account than the account that owns the source bucket. If you use SSE-KMS encryption for the cross-account operations of Amazon S3 inventory, when you configure S3 inventory, we recommend you use a fully qualified KMS key ARN. For more information, see [Using SSE-KMS encryption for cross-account operations](#) and [ServerSideEncryptionByDefault](#) in the *Amazon Simple Storage Service API Reference*.

Creating a destination bucket policy

If you create your inventory configuration through the Amazon S3 console, Amazon S3 automatically creates a bucket policy on the destination bucket that grants Amazon S3 write permission to the bucket. However, if you create your inventory configuration through the AWS CLI, SDKs, or the REST API, you must manually add a bucket policy on the destination bucket. For more information, see [Grant permissions for S3 Inventory and S3 analytics](#). The Amazon S3 Inventory destination bucket policy allows Amazon S3 to write data for the inventory reports to the bucket.

If an error occurs when you try to create the bucket policy, you are given instructions on how to fix it. For example, if you choose a destination bucket in another AWS account and don't have permissions to read and write to the bucket policy, you see an error message.

In this case, the destination bucket owner must add the displayed bucket policy to the destination bucket. If the policy is not added to the destination bucket, you won't get an inventory report because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, the correct account ID of the source bucket owner must be substituted in the policy.

Granting Amazon S3 permission to use your customer managed key for encryption

To grant Amazon S3 permission to use your AWS Key Management Service (AWS KMS) customer managed key for server-side encryption, you must use a key policy. To update your key policy so that you can use your customer managed key, use the following procedure.

To grant permissions to encrypt using your customer managed key

1. Using the AWS account that owns the customer managed key, sign into the AWS Management Console.
2. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
3. To change the AWS Region, use the Region selector in the upper-right corner of the page.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the customer managed key that you want to use to encrypt your inventory files.
6. In the **Key policy** section, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.

8. On the **Edit key policy** page, add the following lines to the existing key policy. For *source-account-id* and *source-bucket-name*, supply the appropriate values for your use case.

```
{  
    "Sid": "Allow Amazon S3 use of the customer managed key",  
    "Effect": "Allow",  
    "Principal": {  
        "Service": "s3.amazonaws.com"  
    },  
    "Action": [  
        "kms:GenerateDataKey"  
    ],  
    "Resource": "*",  
    "Condition":{  
        "StringEquals":{  
            "aws:SourceAccount":"source-account-id"  
        },  
        "ArnLike":{  
            "aws:SourceARN": "arn:aws:s3:::source-bucket-name"  
        }  
    }  
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following links in the *AWS Key Management Service Developer Guide*:

- [Getting Started](#)
- [Using Key Policies in AWS KMS](#)

Configuring inventory by using the S3 console

Use these instructions to configure inventory by using the S3 console.

Note

It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**. In the **Buckets** list, choose the name of the bucket that you want to configure Amazon S3 Inventory for.
3. Choose the **Management** tab.
4. Under **Inventory configurations**, choose **Create inventory configuration**.
5. For **Inventory configuration name**, enter a name.
6. For **Inventory scope**, do the following:
 - Enter an optional prefix.
 - Choose which object versions to include, either **Current versions only** or **Include all versions**.
7. Under **Report details**, choose the location of the AWS account that you want to save the reports to: **This account** or **A different account**.
8. Under **Destination**, choose the destination bucket where you want the inventory reports to be saved.

The destination bucket must be in the same AWS Region as the bucket for which you are setting up the inventory. The destination bucket can be in a different AWS account. When specifying the destination bucket, you can also include an optional prefix to group your inventory reports together.

Under the **Destination** bucket field, you see the **Destination bucket permission** statement that is added to the destination bucket policy to allow Amazon S3 to place data in that bucket. For more information, see [Creating a destination bucket policy](#).

9. Under **Frequency**, choose how often the report will be generated, **Daily** or **Weekly**.
10. For **Output format**, choose one of the following formats for the report:
 - **CSV** – If you plan to use this inventory report with S3 Batch Operations or if you want to analyze this report in another tool, such as Microsoft Excel, choose **CSV**.
 - **Apache ORC**
 - **Apache Parquet**
11. Under **Status**, choose **Enable** or **Disable**.
12. To configure server-side encryption, under **Inventory report encryption**, follow these steps:

- a. Under **Server-side encryption**, choose **Do not specify an encryption key** or **Specify an encryption key** to encrypt data.
 - To keep the bucket settings for default server-side encryption of objects when storing them in Amazon S3, choose **Do not specify an encryption key**. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies an S3 Bucket Key at the destination bucket.

 **Note**

If the bucket policy for the specified destination requires objects to be encrypted before storing them in Amazon S3, you must specify an encryption key. Otherwise, copying objects to the destination will fail.

- To encrypt objects before storing them in Amazon S3, choose **Specify an encryption key**.
- b. If you chose **Specify an encryption key**, under **Encryption type**, you need to choose **Amazon S3 managed key (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. SSE-KMS provides you with more control over your key. For more information about SSE-S3, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#). For more information about SSE-KMS, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

 **Note**

To encrypt the inventory list file with SSE-KMS, you must grant Amazon S3 permission to use the customer managed key. For instructions, see [Grant Amazon S3 Permission to Encrypt Using Your KMS Keys](#).

- c. If you chose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify your AWS KMS key through one of the following options.
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose a symmetric encryption KMS key in the same Region as your bucket from the list of available keys.

Note

Both the AWS managed key (aws/s3) and your customer managed keys appear in the list. However, the AWS managed key (aws/s3) is not supported for SSE-KMS encryption with S3 Inventory.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

13. For **Additional metadata fields**, select one or more of the following to add to the inventory report:

- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **Multipart upload** – Specifies that the object was uploaded as a multipart upload. For more information, see [Uploading and copying objects using multipart upload](#).
- **Replication status** – The replication status of the object. For more information, see [Getting replication status information](#).
- **Encryption status** – The server-side encryption type that's used to encrypt the object. For more information, see [Protecting data with server-side encryption](#).
- **Bucket Key status** – Indicates whether a bucket-level key generated by AWS KMS applies to the object. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information about this field, see [Working with the Object ACL field](#). For more information about ACL, see [Access control list \(ACL\) overview](#).
- **Object owner** – The owner of the object.
- **Storage class** – The storage class that's used for storing the object.

- **Intelligent-Tiering: Access tier** – Indicates the access tier (frequent or infrequent) of the object if it was stored in the S3 Intelligent-Tiering storage class. For more information, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).
- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag might or might not be an MD5 digest of the object data. Whether it is depends on how the object was created and how it is encrypted. For more information, see [Object](#) in the *Amazon Simple Storage Service API Reference*.
- **Checksum algorithm** – Indicates the algorithm that is used to create the checksum for the object.
- **All Object Lock configurations** – The Object Lock status of the object, including the following settings:
 - **Object Lock: Retention mode** – The level of protection applied to the object, either *Governance* or *Compliance*.
 - **Object Lock: Retain until date** – The date until which the locked object cannot be deleted.
 - **Object Lock: Legal hold status** – The legal hold status of the locked object.

For information about S3 Object Lock, see [How S3 Object Lock works](#).

For more information about the contents of an inventory report, see [Amazon S3 Inventory list](#).

14. Choose **Create**.

When an inventory list is published, you can query the inventory list file with Amazon S3 Select. For more information about how to locate your inventory list and query the inventory list file with Amazon S3 Select, see [Locating your inventory list](#).

Using the REST API to work with S3 Inventory

The following are the REST operations that are used for working with Amazon S3 Inventory.

- [DeleteBucketInventoryConfiguration](#)
- [GetBucketInventoryConfiguration](#)
- [ListBucketInventoryConfigurations](#)
- [PutBucketInventoryConfiguration](#)

Setting up Amazon S3 Event Notifications for inventory completion

You can set up an Amazon S3 event notification to receive notice when the manifest checksum file is created, which indicates that an inventory list has been added to the destination bucket. The manifest is an up-to-date list of all the inventory lists at the destination location.

Amazon S3 can publish events to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

The following notification configuration defines that all `manifest.checksum` files newly added to the destination bucket are processed by the AWS Lambda `cloud-function-list-write`.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>destination-prefix/source-bucket</Value>
        </FilterRule>
        <FilterRule>
          <Name>suffix</Name>
          <Value>checksum</Value>
        </FilterRule>
      </S3Key>
    </Filter>
    <Cloudcode>arn:aws:lambda:us-west-2:222233334444:cloud-function-list-write</Cloudcode>
    <Event>s3:ObjectCreated:*</Event>
  </QueueConfiguration>
</NotificationConfiguration>
```

For more information, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Locating your inventory list

When an inventory list is published, the manifest files are published to the following location in the destination bucket.

```
destination-prefix/source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/manifest.json  
destination-prefix/source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/manifest.checksum  
destination-prefix/source-bucket/config-ID/hive/dt=YYYY-MM-DD-HH-MM/symlink.txt
```

- **destination-prefix** is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location within the destination bucket.
- **source-bucket** is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- **config-ID** is added to prevent collisions with multiple inventory reports from the same source bucket that are sent to the same destination bucket. The **config-ID** comes from the inventory report configuration, and is the name for the report that is defined during setup.
- **YYYY-MM-DDTHH-MMZ** is the timestamp that consists of the start time and the date when the inventory report generation process begins scanning the bucket; for example, 2016-11-06T21-32Z.
- **manifest.json** is the manifest file.
- **manifest.checksum** is the MD5 hash of the content of the **manifest.json** file.
- **symlink.txt** is the Apache Hive-compatible manifest file.

The inventory lists are published daily or weekly to the following location in the destination bucket.

```
destination-prefix/source-bucket/config-ID/data/example-file-name.csv.gz  
...  
destination-prefix/source-bucket/config-ID/data/example-file-name-1.csv.gz
```

- **destination-prefix** is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location in the destination bucket.
- **source-bucket** is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- **example-file-name.csv.gz** is one of the CSV inventory files. ORC inventory names end with the file name extension **.orc**, and Parquet inventory names end with the file name extension **.parquet**.

You can query an inventory list file with Amazon S3 Select. In the Amazon S3 console, choose the name of the inventory list (for example, *destination-prefix/source-bucket/config-ID/data/example-file-name.csv.gz*). Then, choose **Object actions** and **Query with S3 Select**. For an example of how to use an S3 Select aggregate function to query an inventory list file, see [SUM example](#).

Inventory manifest

The manifest files `manifest.json` and `symlink.txt` describe where the inventory files are located. Whenever a new inventory list is delivered, it is accompanied by a new set of manifest files. These files might overwrite each other. In versioning-enabled buckets, Amazon S3 creates new versions of the manifest files.

Each manifest contained in the `manifest.json` file provides metadata and other basic information about an inventory. This information includes the following:

- The source bucket name
- The destination bucket name
- The version of the inventory
- The creation timestamp in the epoch date format that consists of the start time and the date when the inventory report generation process begins scanning the bucket
- The format and schema of the inventory files
- A list of the inventory files that are in the destination bucket

Whenever a `manifest.json` file is written, it is accompanied by a `manifest.checksum` file that is the MD5 hash of the content of the `manifest.json` file.

Example Inventory manifest in a `manifest.json` file

The following examples show an inventory manifest in a `manifest.json` file for CSV, ORC, and Parquet-formatted inventories.

CSV

The following is an example of a manifest in a `manifest.json` file for a CSV-formatted inventory.

```
{  
    "sourceBucket": "example-source-bucket",  
    "destinationBucket": "arn:aws:s3:::example-inventory-destination-bucket",  
    "version": "2016-11-30",  
    "creationTimestamp" : "1514944800000",  
    "fileFormat": "CSV",  
    "fileSchema": "Bucket, Key, VersionId, IsLatest, IsDeleteMarker,  
Size, LastModifiedDate, ETag, StorageClass, IsMultipartUploaded,  
ReplicationStatus, EncryptionStatus, ObjectLockRetainUntilDate, ObjectLockMode,  
ObjectLockLegalHoldStatus, IntelligentTieringAccessTier, BucketKeyStatus,  
ChecksumAlgorithm, ObjectAccessControlList, ObjectOwner",  
    "files": [  
        {  
            "key": "Inventory/example-source-bucket/2016-11-06T21-32Z/  
files/939c6d46-85a9-4ba8-87bd-9db705a579ce.csv.gz",  
            "size": 2147483647,  
            "MD5checksum": "f11166069f1990abeb9c97ace9cdfabc"  
        }  
    ]  
}
```

ORC

The following is an example of a manifest in a `manifest.json` file for an ORC-formatted inventory.

```
{  
    "sourceBucket": "example-source-bucket",  
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",  
    "version": "2016-11-30",  
    "creationTimestamp" : "1514944800000",  
    "fileFormat": "ORC",  
    "fileSchema":  
"struct<bucket:string,key:string,version_id:string,is_latest:boolean,is_delete_marker:boolean>  
    "files": [  
        {  
            "key": "inventory/example-source-bucket/data/  
d794c570-95bb-4271-9128-26023c8b4900.orc",  
            "size": 56291,  
            "MD5checksum": "5925f4e78e1695c2d020b9f6eexample"  
        }  
    ]  
}
```

```
}
```

Parquet

The following is an example of a manifest in a `manifest.json` file for a Parquet-formatted inventory.

```
{
    "sourceBucket": "example-source-bucket",
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",
    "version": "2016-11-30",
    "creationTimestamp" : "1514944800000",
    "fileFormat": "Parquet",
    "fileSchema": "message s3.inventory { required binary bucket (UTF8);
required binary key (UTF8); optional binary version_id (UTF8); optional boolean
is_latest; optional boolean is_delete_marker; optional int64 size; optional
int64 last_modified_date (TIMESTAMP_MILLIS); optional binary e_tag (UTF8);
optional binary storage_class (UTF8); optional boolean is_multipart_uploaded;
optional binary replication_status (UTF8); optional binary encryption_status
(UTF8); optional int64 object_lock_retain_until_date (TIMESTAMP_MILLIS); optional
binary object_lock_mode (UTF8); optional binary object_lock_legal_hold_status
(UTF8); optional binary intelligent_tiering_access_tier (UTF8); optional binary
bucket_key_status (UTF8); optional binary checksum_algorithm (UTF8); optional
binary object_access_control_list (UTF8); optional binary object_owner (UTF8);}",
    "files": [
        {
            "key": "inventory/example-source-bucket/data/
d754c470-85bb-4255-9218-47023c8b4910.parquet",
            "size": 56291,
            "MD5checksum": "5825f2e18e1695c2d030b9f6eexample"
        }
    ]
}
```

The `symlink.txt` file is an Apache Hive-compatible manifest file that allows Hive to automatically discover inventory files and their associated data files. The Hive-compatible manifest works with the Hive-compatible services Athena and Amazon Redshift Spectrum. It also works with Hive-compatible applications, including [Presto](#), [Apache Hive](#), [Apache Spark](#), and many others.

Important

The `symlink.txt` Apache Hive-compatible manifest file does not currently work with AWS Glue.

Reading the `symlink.txt` file with [Apache Hive](#) and [Apache Spark](#) is not supported for ORC and Parquet-formatted inventory files.

Querying Amazon S3 Inventory with Amazon Athena

You can query Amazon S3 Inventory files with standard SQL queries by using Amazon Athena in all Regions where Athena is available. To check for AWS Region availability, see the [AWS Region Table](#).

Athena can query Amazon S3 Inventory files in [Apache optimized row columnar \(ORC\)](#), [Apache Parquet](#), or comma-separated values (CSV) format. When you use Athena to query inventory files, we recommend that you use ORC-formatted or Parquet-formatted inventory files. The ORC and Parquet formats provide faster query performance and lower query costs. ORC and Parquet are self-describing, type-aware columnar file formats designed for [Apache Hadoop](#). The columnar format lets the reader read, decompress, and process only the columns that are required for the current query. The ORC and Parquet formats for Amazon S3 Inventory are available in all AWS Regions.

To use Athena to query Amazon S3 Inventory files

1. Create an Athena table. For information about creating a table, see [Creating Tables in Amazon Athena](#) in the *Amazon Athena User Guide*.
2. Create your query by using one of the following sample query templates, depending on whether you're querying an ORC-formatted, a Parquet-formatted, or a CSV-formatted inventory report.
 - When you're using Athena to query an ORC-formatted inventory report, use the following sample query as a template.

The following sample query includes all the optional fields in an ORC-formatted inventory report.

To use this sample query, do the following:

- Replace `your_table_name` with the name of the Athena table that you created.

- Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
- Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

s3://*DOC-EXAMPLE-BUCKET*/*config-ID*/hive/

- Replace the *2022-01-01-00-00* date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see [Partitioning data in Athena](#).

```
CREATE EXTERNAL TABLE your_table_name(  
    bucket string,  
    key string,  
    version_id string,  
    is_latest boolean,  
    is_delete_marker boolean,  
    size bigint,  
    last_modified_date timestamp,  
    e_tag string,  
    storage_class string,  
    is_multipart_uploaded boolean,  
    replication_status string,  
    encryption_status string,  
    object_lock_retain_until_date bigint,  
    object_lock_mode string,  
    object_lock_legal_hold_status string,  
    intelligent_tiering_access_tier string,  
    bucket_key_status string,  
    checksum_algorithm string,  
    object_access_control_list string,  
    object_owner string  
) PARTITIONED BY (  
    dt string  
)  
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'  
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'  
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'  
LOCATION 's3://source-bucket/config-ID/hive/'  
TBLPROPERTIES (  
    "projection.enabled" = "true",  
    "projection.dt.type" = "date",
```

```
"projection.dt.format" = "yyyy-MM-dd-HH-mm",
"projection.dt.range" = "2022-01-01-00-00,NOW",
"projection.dt.interval" = "1",
"projection.dt.interval.unit" = "HOURS"
);
```

- When you're using Athena to query a Parquet-formatted inventory report, use the sample query for an ORC-formatted report. However, use the following Parquet SerDe in place of the ORC SerDe in the ROW FORMAT SERDE statement.

```
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe'
```

- When you're using Athena to query a CSV-formatted inventory report, use the following sample query as a template.

The following sample query includes all the optional fields in an CSV-formatted inventory report.

To use this sample query, do the following:

- Replace *your_table_name* with the name of the Athena table that you created.
- Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
- Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

```
s3://DOC-EXAMPLE-BUCKET/config-ID/hive/
```

- Replace the **2022-01-01-00-00** date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see [Partitioning data in Athena](#).

```
CREATE EXTERNAL TABLE your_table_name(  
    bucket string,  
    key string,  
    version_id string,  
    is_latest boolean,  
    is_delete_marker boolean,  
    size string,  
    last_modified_date string,  
    e_tag string,  
    storage_class string,
```

```
        is_multipart_uploaded boolean,
        replication_status string,
        encryption_status string,
        object_lock_retain_until_date string,
        object_lock_mode string,
        object_lock_legal_hold_status string,
        intelligent_tiering_access_tier string,
        bucket_key_status string,
        checksum_algorithm string,
        object_access_control_list string,
        object_owner string
    ) PARTITIONED BY (
        dt string
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.OpenCSVSerde'
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'
LOCATION 's3://source-bucket/config-ID/hive/
TBLPROPERTIES (
    "projection.enabled" = "true",
    "projection.dt.type" = "date",
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",
    "projection.dt.range" = "2022-01-01-00-00,NOW",
    "projection.dt.interval" = "1",
    "projection.dt.interval.unit" = "HOURS"
);
```

3. You can now run various queries on your inventory, as shown in the following examples. Replace each *user input placeholder* with your own information.

```
# Get a list of the latest inventory report dates available.
SELECT DISTINCT dt FROM your_table_name ORDER BY 1 DESC limit 10;

# Get the encryption status for a provided report date.
SELECT encryption_status, count(*) FROM your_table_name WHERE dt = 'YYYY-MM-DD-HH-MM' GROUP BY encryption_status;

# Get the encryption status for inventory report dates in the provided range.
SELECT dt, encryption_status, count(*) FROM your_table_name
WHERE dt > 'YYYY-MM-DD-HH-MM' AND dt < 'YYYY-MM-DD-HH-MM' GROUP BY dt,
encryption_status;
```

When you configure S3 Inventory to add the Object Access Control List (Object ACL) field to an inventory report, the report displays the value for the Object ACL field as a base64-encoded string. To get the decoded value in JSON for the Object ACL field, you can query this field by using Athena. See the following query examples. For more information about the Object ACL field, see [Working with the Object ACL field](#).

```
# Get the S3 keys that have Object ACL grants with public access.  
WITH grants AS (  
    SELECT key,  
           CAST(  
                 json_extract(from_utf8(from_base64(object_access_control_list)),  
'$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))  
             ) AS grants_array  
    FROM your_table_name  
)  
SELECT key,  
       grants_array,  
       grant  
FROM grants, UNNEST(grants_array) AS t(grant)  
WHERE element_at(grant, 'uri') = 'http://acs.amazonaws.com/groups/global/AllUsers'
```

```
# Get the S3 keys that have Object ACL grantees in addition to the object owner.  
WITH grants AS  
    (SELECT key,  
         from_utf8(from_base64(object_access_control_list)) AS  
object_access_control_list,  
         object_owner,  
         CAST(json_extract(from_utf8(from_base64(object_access_control_list)),  
'$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))) AS grants_array  
    FROM your_table_name)  
SELECT key,  
       grant,  
       objectowner  
FROM grants, UNNEST(grants_array) AS t(grant)  
WHERE cardinality(grants_array) > 1 AND element_at(grant, 'canonicalId') !=  
object_owner;
```

```
# Get the S3 keys with READ permission that is granted in the Object ACL.
```

```
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
            '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
    grants_array,
    grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'permission') = 'READ';
```

```
# Get the S3 keys that have Object ACL grants to a specific canonical user ID.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
            '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
    grants_array,
    grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'canonicalId') = 'user-canonical-id';
```

```
# Get the number of grantees on the Object ACL.
SELECT key,
    object_access_control_list,
    json_array_length(json_extract(object_access_control_list, '$.grants')) AS grants_count
FROM your_table_name;
```

For more information about using Athena, see the [Amazon Athena User Guide](#).

Converting empty version ID strings in Amazon S3 Inventory reports to null strings

Note

The following procedure applies only to Amazon S3 Inventory reports that include all versions, and only if the "all versions" reports are used as manifests for S3 Batch Operations on buckets that have S3 Versioning enabled. You are not required to convert strings for S3 Inventory reports that specify the current version only.

You can use S3 Inventory reports as manifests for S3 Batch Operations. However, when S3 Versioning is enabled on a bucket, S3 Inventory reports that include all versions mark any null-versioned objects with empty strings in the version ID field. When an Inventory Report includes all object version IDs, Batch Operations recognizes null strings as version IDs, but not empty strings.

When an S3 Batch Operations job uses an "all versions" S3 Inventory report as a manifest, it fails all tasks on objects that have an empty string in the version ID field. To convert empty strings in the version ID field of the S3 Inventory report to null strings for Batch Operations, use the following procedure.

Update an Amazon S3 Inventory report for use with Batch Operations

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Navigate to your S3 Inventory report. The inventory report is located in the destination bucket that you specified while configuring your inventory report. For more information about locating inventory reports, see [Locating your inventory list](#).
 - a. Choose the destination bucket.
 - b. Choose the folder. The folder is named after the original source bucket.
 - c. Choose the folder named after the inventory configuration.
 - d. Select the check box next to the folder named **hive**. At the top of the page, choose **Copy S3 URI** to copy the S3 URI for the folder.
3. Open the Amazon Athena console at <https://console.aws.amazon.com/athena/>.
4. In the query editor, choose **Settings**, then choose **Manage**. On the **Manage settings** page, for **Location of query result**, choose an S3 bucket to store your query results in.

5. In the query editor, create an Athena table to hold the data in the inventory report using the following command. Replace *table_name* with a name of your choosing, and in the LOCATION clause, insert the S3 URI that you copied earlier. Then choose **Run** to run the query.

```
CREATE EXTERNAL TABLE table_name(bucket string, key string,  
version_id string) PARTITIONED BY (dt string)ROW FORMAT SERDE  
'org.apache.hadoop.hive.serde2.OpenCSVSerde' STORED AS INPUTFORMAT  
'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat' OUTPUTFORMAT  
'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat' LOCATION 'Copied S3 URI';
```

6. To clear the query editor, choose **Clear**. Then load the inventory report into the table using the following command. Replace *table_name* with the one that you chose in the prior step. Then choose **Run** to run the query.

```
MSCK REPAIR TABLE table_name;
```

7. To clear the query editor, choose **Clear**. Run the following SELECT query to retrieve all entries in the original inventory report and replace any empty version IDs with null strings. Replace *table_name* with the one that you chose earlier, and replace *YYYY-MM-DD-HH-MM* in the WHERE clause with the date of the inventory report that you want this tool to run on. Then choose **Run** to run the query.

```
SELECT bucket as Bucket, key as Key, CASE WHEN version_id = '' THEN 'null' ELSE  
version_id END as VersionId FROM table_name WHERE dt = 'YYYY-MM-DD-HH-MM';
```

8. Return to the Amazon S3 console (<https://console.aws.amazon.com/s3/>), and navigate to the S3 bucket that you chose for **Location of query result** earlier. Inside, there should be a series of folders ending with the date.

For example, you should see something like `s3://DOC-EXAMPLE-BUCKET/query-result-location/Unsaved/2021/10/07/`. You should see .csv files containing the results of the SELECT query that you ran.

Choose the CSV file with the latest modified date. Download this file to your local machine for the next step.

9. The generated CSV file contains a header row. To use this CSV file as input for an S3 Batch Operations job, you must remove the header row, because Batch Operations doesn't support header rows on CSV manifests.

To remove the header row, you can run one of the following commands on the file. Replace *file.csv* with the name of your CSV file.

For macOS and Linux machines, run the tail command in a Terminal window.

```
tail -n +2 file.csv > tmp.csv && mv tmp.csv file.csv
```

For Windows machines, run the following script in a Windows PowerShell window. Replace *File-location* with the path to your file, and *file.csv* with the file name.

```
$ins = New-Object System.IO.StreamReader File-location\file.csv
$outs = New-Object System.IO.StreamWriter File-location\temp.csv
try {
    $skip = 0
    while ( !$ins.EndOfStream ) {
        $line = $ins.ReadLine();
        if ( $skip -ne 0 ) {
            $outs.WriteLine($line);
        } else {
            $skip = 1
        }
    }
} finally {
    $outs.Close();
    $ins.Close();
}
Move-Item File-location\temp.csv File-location\file.csv -Force
```

10. After removing the header row from the CSV file, you are ready to use it as a manifest in an S3 Batch Operations job. Upload the CSV file to an S3 bucket or location of your choosing, and then create a Batch Operations job using the CSV file as the manifest.

For more information about creating a Batch Operations job, see [Creating an S3 Batch Operations job](#).

Working with the Object ACL field

An Amazon S3 Inventory report contains a list of the objects in the S3 source bucket and metadata for each object. The Object access control list (ACL) field is a metadata field that is available in

Amazon S3 Inventory. Specifically, the Object ACL field contains the access control list (ACL) for each object. The ACL for an object defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information, see [Access control list \(ACL\) overview](#) and [Amazon S3 Inventory list](#).

The Object ACL field in Amazon S3 Inventory reports is defined in JSON format. The JSON data includes the following fields:

- **version** – The version of the Object ACL field format in the inventory reports. It's in date format yyyy-mm-dd.
- **status** – Possible values are AVAILABLE or UNAVAILABLE to indicate whether an Object ACL is available for an object. When the status for the Object ACL is UNAVAILABLE, the value of the Object Owner field in the inventory report is also UNAVAILABLE.
- **grants** – Grantee-permission pairs that list the permission status of each grantee that is granted by the Object ACL. The available values for a grantee are CanonicalUser and Group. For more information about grantees, see [Grantees in access control lists](#).

For a grantee with the Group type, a grantee-permission pair includes the following attributes:

- **uri** – A predefined Amazon S3 group.
- **permission** – The ACL permissions that are granted on the object. For more information, see [ACL permissions on an object](#).
- **type** – The type Group, which denotes that the grantee is group.

For a grantee with the CanonicalUser type, a grantee-permission pair includes the following attributes:

- **canonicalId** – An obfuscated form of the AWS account ID. For more information, see [Finding the canonical user ID for your AWS account](#).

 **Note**

If a grantee in an ACL is the email address of an AWS account, S3 Inventory uses the canonicalId of that AWS account and the CanonicalUser type to specify this grantee. For more information, see [Grantees in access control lists](#).

- **permission** – The ACL permissions that are granted on the object. For more information, see [ACL permissions on an object](#).
- **type** – The type CanonicalUser, which denotes that the grantee is an AWS account.

The following example shows possible values for the Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {  
            "uri": "http://acs.amazonaws.com/groups/global/AllUsers",  
            "permission": "READ",  
            "type": "Group"  
        }, {  
            "canonicalId": "example-canonical-id",  
            "permission": "FULL_CONTROL",  
            "type": "CanonicalUser"  
        }]  
}
```

Note

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.

For example, suppose that you have the following Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {  
            "canonicalId": "example-canonical-user-ID",  
            "type": "CanonicalUser",  
            "permission": "READ"  
        }]  
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQU1MQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2FsSw
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see [Querying Amazon S3 Inventory with Amazon Athena](#).

Replicating objects

Replication enables automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. You can replicate objects to a single destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Regions or within the same Region as the source bucket.

To automatically replicate new objects as they are written to the bucket, use live replication, such as Cross-Region Replication (CRR). To replicate existing objects to a different bucket on demand, use S3 Batch Replication. For more information about replicating existing objects, see [When to use S3 Batch Replication](#).

To enable CRR, you add a replication configuration to your source bucket. The minimum configuration must provide the following:

- The destination bucket or buckets where you want Amazon S3 to replicate objects
- An AWS Identity and Access Management (IAM) role that Amazon S3 can assume to replicate objects on your behalf

Additional configuration options are available. For more information, see [Additional replication configurations](#).

To get detailed metrics for S3 Replication, including replication rule count metrics, you can use Amazon S3 Storage Lens. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to protect your data](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

Topics

- [Why use replication](#)
- [When to use Cross-Region Replication](#)
- [When to use Same-Region Replication](#)
- [When to use two-way replication \(bi-directional replication\)](#)
- [When to use S3 Batch Replication](#)
- [Requirements for replication](#)

- [What does Amazon S3 replicate?](#)
- [Setting up replication](#)
- [Replicating existing objects with S3 Batch Replication](#)
- [Additional replication configurations](#)
- [Getting replication status information](#)
- [Additional considerations](#)

Why use replication

Replication can help you do the following:

- **Replicate objects while retaining metadata** – You can use replication to make copies of your objects that retain all metadata, such as the original object creation times and version IDs. This capability is important if you must ensure that your replica is identical to the source object.
- **Replicate objects into different storage classes** – You can use replication to directly put objects into S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or another storage class in the destination buckets. You can also replicate your data to the same storage class and use lifecycle configurations on the destination buckets to move your objects to a colder storage class as they age.
- **Maintain object copies under different ownership** – Regardless of who owns the source object, you can tell Amazon S3 to change replica ownership to the AWS account that owns the destination bucket. This is referred to as the *owner override* option. You can use this option to restrict access to object replicas.
- **Keep objects stored over multiple AWS Regions** – To ensure geographic differences in where your data is kept, you can set multiple destination buckets across different AWS Regions. This feature might help you meet certain compliance requirements.
- **Replicate objects within 15 minutes** – To replicate your data in the same AWS Region or across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called “Using S3 Replication Time Control”](#).
- **Sync buckets, replicate existing objects, and replicate previously failed or replicated objects** – To sync buckets and replicate existing objects, use Batch Replication as an on-demand replication action. For more information about when to use Batch Replication, see [When to use S3 Batch Replication](#).

- **Replicate objects and fail over to a bucket in another AWS Region** – To keep all metadata and objects in sync across buckets during data replication, use two-way replication (also known as bi-directional replication) rules before configuring Amazon S3 Multi-Region Access Point failover controls. Two-way replication rules help ensure that when data is written to the S3 bucket that traffic fails over to, that data is then replicated back to the source bucket.

 **Note**

S3 RTC does not apply to Batch Replication. Batch Replication is an on-demand replication job, and can be tracked with S3 Batch Operations. For more information, see [Tracking job status and completion reports](#).

When to use Cross-Region Replication

S3 Cross-Region Replication (CRR) is used to copy objects across Amazon S3 buckets in different AWS Regions. CRR can help you do the following:

- **Meet compliance requirements** – Although Amazon S3 stores your data across multiple geographically distant Availability Zones by default, compliance requirements might dictate that you store data at even greater distances. To satisfy these requirements, use Cross-Region Replication to replicate data between distant AWS Regions.
- **Minimize latency** – If your customers are in two geographic locations, you can minimize latency in accessing objects by maintaining object copies in AWS Regions that are geographically closer to your users.
- **Increase operational efficiency** – If you have compute clusters in two different AWS Regions that analyze the same set of objects, you might choose to maintain object copies in those Regions.

When to use Same-Region Replication

Same-Region Replication (SRR) is used to copy objects across Amazon S3 buckets in the same AWS Region. SRR can help you do the following:

- **Aggregate logs into a single bucket** – If you store logs in multiple buckets or across multiple accounts, you can easily replicate logs into a single, in-Region bucket. Doing so allows for simpler processing of logs in a single location.

- **Configure live replication between production and test accounts** – If you or your customers have production and test accounts that use the same data, you can replicate objects between those multiple accounts, while maintaining object metadata.
- **Abide by data sovereignty laws** – You might be required to store multiple copies of your data in separate AWS accounts within a certain Region. Same-Region Replication can help you automatically replicate critical data when compliance regulations don't allow the data to leave your country.

When to use two-way replication (bi-directional replication)

- **Build shared datasets across multiple AWS Regions** – With replica modification sync, you can easily replicate metadata changes, such as object access control lists (ACLs), object tags, or object locks, on replication objects. This two-way replication is important if you want to keep all objects and object metadata changes in sync. You can [enable replica modification sync](#) on a new or existing replication rule when performing two-way replication between two or more buckets in the same or different AWS Regions.
- **Keep data synchronized across Regions during failover** – You can synchronize data in buckets between AWS Regions by configuring two-way replication rules with S3 Cross-Region Replication (CRR) directly from a Multi-Region Access Point. To make an informed decision on when to initiate failover, you can also enable S3 replication metrics to monitor the replication in Amazon CloudWatch, S3 Replication Time Control (S3 RTC), or from the Multi-Region Access Point.
- **Make your application highly available** – Even in the event of a Regional traffic disruption, you can use two-way replication rules to keep all metadata and objects in sync across buckets during data replication.

When to use S3 Batch Replication

Batch Replication replicates existing objects to different buckets as an on-demand option. Unlike live replication, these jobs can be run as needed. Batch Replication can help you do the following:

- **Replicate existing objects** – You can use Batch Replication to replicate objects that were added to the bucket before Same-Region Replication or Cross-Region Replication were configured.
- **Replicate objects that previously failed to replicate** – You can filter a Batch Replication job to attempt to replicate objects with a replication status of **FAILED**.

- **Replicate objects that were already replicated** – You might be required to store multiple copies of your data in separate AWS accounts or AWS Regions. Batch Replication can replicate existing objects to newly added destinations.
- **Replicate replicas of objects that were created from a replication rule** – Replication configurations create replicas of objects in destination buckets. Replicas of objects can be replicated only with Batch Replication.

Requirements for replication

Replication requires the following:

- The source bucket owner must have the source and destination AWS Regions enabled for their account. The destination bucket owner must have the destination Region enabled for their account.

For more information about enabling or disabling an AWS Region, see [Managing AWS Regions](#) in the [AWS General Reference](#).

- Both source and destination buckets must have versioning enabled. For more information about versioning, see [Using versioning in S3 buckets](#).
- Amazon S3 must have permissions to replicate objects from the source bucket to the destination bucket or buckets on your behalf. For more information about these permissions, see [Setting up permissions](#).
- If the owner of the source bucket doesn't own the object in the bucket, the object owner must grant the bucket owner READ and READ_ACP permissions with the object access control list (ACL). For more information, see [Access control list \(ACL\) overview](#).
- If the source bucket has S3 Object Lock enabled, the destination buckets must also have S3 Object Lock enabled.

To enable replication on a bucket that has Object Lock enabled, you must use the AWS Command Line Interface, REST API, or AWS SDKs. For more general information, see [Using S3 Object Lock](#).

 **Note**

You must grant two new permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two new permissions are s3:GetObjectRetention and s3:GetObjectLegalHold. If the

role has an s3:Get* permission, it satisfies the requirement. For more information, see [Setting up permissions](#).

For more information, see [Setting up replication](#).

If you are setting the replication configuration in a *cross-account scenario*, where the source and destination buckets are owned by different AWS accounts, the following additional requirement applies:

- The owner of the destination buckets must grant the owner of the source bucket permissions to replicate objects with a bucket policy. For more information, see [Granting permissions when the source and destination buckets are owned by different AWS accounts](#).
- The destination buckets cannot be configured as Requester Pays buckets. For more information, see [Using Requester Pays buckets for storage transfers and usage](#).

What does Amazon S3 replicate?

Amazon S3 replicates only specific items in buckets that are configured for replication.

Topics

- [What is replicated with replication configurations?](#)
- [What isn't replicated with replication configurations?](#)
- [Default bucket encryption and replication](#)

What is replicated with replication configurations?

By default, Amazon S3 replicates the following:

- Objects created after you add a replication configuration.
- Unencrypted objects.
- Objects encrypted using customer provided keys (SSE-C), objects encrypted at rest under an Amazon S3 managed key (SSE-S3) or a KMS key stored in AWS Key Management Service (SSE-KMS). For more information, see [the section called “Replicating encrypted objects \(SSE-C, SSE-S3, SSE-KMS, DSSE-KMS\)”](#).

- Object metadata from the source objects to the replicas. For information about replicating metadata from the replicas to the source objects, see [Replicating metadata changes with Amazon S3 replica modification sync](#).
- Only objects in the source bucket for which the bucket owner has permissions to read objects and access control lists (ACLs).

For more information about resource ownership, see [Amazon S3 bucket and object ownership](#).

- Object ACL updates, unless you direct Amazon S3 to change the replica ownership when source and destination buckets aren't owned by the same accounts.

For more information, see [Changing the replica owner](#).

It can take a while until Amazon S3 can bring the two ACLs in sync. This change in ownership applies only to objects created after you add a replication configuration to the bucket.

- Object tags, if there are any.
- S3 Object Lock retention information, if there is any.

When Amazon S3 replicates objects that have retention information applied, it applies those same retention controls to your replicas, overriding the default retention period configured on your destination buckets. If you don't have retention controls applied to the objects in your source bucket, and you replicate into destination buckets that have a default retention period set, the destination bucket's default retention period is applied to your object replicas. For more information, see [Using S3 Object Lock](#).

How delete operations affect replication

If you delete an object from the source bucket, the following actions occur by default:

- If you make a DELETE request without specifying an object version ID, Amazon S3 adds a delete marker. Amazon S3 deals with the delete marker as follows:
 - If you are using the latest version of the replication configuration (that is, you specify the `Filter` element in a replication configuration rule), Amazon S3 does not replicate the delete marker by default. However, you can add *delete marker replication* to non-tag-based rules. For more information, see [Replicating delete markers between buckets](#).
 - If you don't specify the `Filter` element, Amazon S3 assumes that the replication configuration is version V1, and it replicates delete markers that resulted from user actions.

However, if Amazon S3 deletes an object due to a lifecycle action, the delete marker is not replicated to the destination buckets.

- If you specify an object version ID to delete in a DELETE request, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination buckets. In other words, it doesn't delete the same object version from the destination buckets. This protects data from malicious deletions.

What isn't replicated with replication configurations?

By default, Amazon S3 doesn't replicate the following:

- Objects in the source bucket that are replicas that were created by another replication rule. For example, suppose you configure replication where bucket A is the source and bucket B is the destination. Now suppose that you add another replication configuration where bucket B is the source and bucket C is the destination. In this case, objects in bucket B that are replicas of objects in bucket A are not replicated to bucket C.

To replicate objects that are replicas, use Batch Replication. Learn more about configuring Batch Replication at [Replicate existing objects](#).

- Objects in the source bucket that have already been replicated to a different destination. For example, if you change the destination bucket in an existing replication configuration, Amazon S3 won't replicate the objects again.

To replicate previously replicated objects, use Batch Replication. Learn more about configuring Batch Replication at [Replicate existing objects](#).

- Batch Replication does not support re-replicating objects that were deleted with the version ID of the object from the destination bucket. To re-replicate these objects, you can copy the source objects in place with a Batch Copy job. Copying those objects in place creates new versions of the objects in the source bucket and initiates replication automatically to the destination. For more information about how to use Batch Copy, see, [Examples that use Batch Operations to copy objects](#).
- By default, when replicating from a different AWS account, delete markers added to the source bucket are not replicated.

For information about how to replicate delete markers, see [Replicating delete markers between buckets](#).

- Objects that are stored in the S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, S3 Intelligent-Tiering Archive Access, or S3 Intelligent-Tiering Deep Archive Access storage classes or tiers. You cannot replicate these objects until you restore them and copy them to a different storage class.

To learn more about S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive, see [Storage classes for archiving objects](#).

To learn more about the S3 Intelligent-Tiering, see [Amazon S3 Intelligent-Tiering](#).

- Objects in the source bucket that the bucket owner doesn't have sufficient permissions to replicate.

For information about how an object owner can grant permissions to a bucket owner, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control](#).

- Updates to bucket-level subresources.

For example, if you change the lifecycle configuration or add a notification configuration to your source bucket, these changes are not applied to the destination bucket. This feature makes it possible to have different configurations on source and destination buckets.

- Actions performed by lifecycle configuration.

For example, if lifecycle configuration is enabled only on your source bucket, Amazon S3 creates delete markers for expired objects but doesn't replicate those markers. If you want the same lifecycle configuration applied to both the source and destination buckets, enable the same lifecycle configuration on both. For more information about lifecycle configuration, see [Managing your storage lifecycle](#).

Default bucket encryption and replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.

- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

Setting up replication

Note

Objects that existed before you set up replication aren't replicated automatically. In other words, Amazon S3 doesn't replicate objects retroactively. To replicate objects that were created before your replication configuration, use S3 Batch Replication. Learn more about configuring Batch Replication at [Replicate existing objects](#).

To enable Same-Region Replication (SRR) or Cross-Region Replication (CRR), add a replication configuration to your source bucket. The configuration tells Amazon S3 to replicate objects as specified. In the replication configuration, you must provide the following:

- The destination buckets** – The bucket or buckets where you want Amazon S3 to replicate the objects.
- The objects that you want to replicate** – You can replicate all of the objects in the source bucket or a subset. You identify a subset by providing a [key name prefix](#), one or more object tags, or both in the configuration.

For example, if you configure a replication rule to replicate only objects with the key name prefix Tax/, Amazon S3 replicates objects with keys such as Tax/doc1 or Tax/doc2. But it doesn't replicate objects with the key Legal/doc3. If you specify both a prefix and one or more tags, Amazon S3 replicates only objects that have the specific key prefix and tags.

In addition to these minimum requirements, you can choose the following options:

- Replica storage class** – By default, Amazon S3 stores object replicas using the same storage class as the source object. You can specify a different storage class for the replicas.
- Replica ownership** – Amazon S3 assumes that an object replica continues to be owned by the owner of the source object. So when it replicates objects, it also replicates the corresponding

object access control list (ACL) or S3 Object Ownership setting. If the source and destination buckets are owned by different AWS accounts, you can configure replication to change the owner of a replica to the AWS account that owns the destination bucket.

You can configure replication by using the REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or the Amazon S3 console.

Amazon S3 also provides API operations to support setting up replication rules. For more information, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket replication](#)
- [GET Bucket replication](#)
- [DELETE Bucket replication](#)

Topics

- [Replication configuration](#)
- [Setting up permissions](#)
- [Walkthroughs: Examples for configuring replication](#)

Replication configuration

Amazon S3 stores a replication configuration as XML. In the replication configuration XML file, you specify an AWS Identity and Access Management (IAM) role and one or more rules.

```
<ReplicationConfiguration>
    <Role>IAM-role-ARN</Role>
    <Rule>
        ...
    </Rule>
    <Rule>
        ...
    </Rule>
    ...
</ReplicationConfiguration>
```

Amazon S3 can't replicate objects without your permission. You grant permissions with the IAM role that you specify in the replication configuration. Amazon S3 assumes the IAM role to replicate

objects on your behalf. You must grant the required permissions to the IAM role first. For more information about managing permissions, see [Setting up permissions](#).

You add one rule in a replication configuration in the following scenarios:

- You want to replicate all objects.
- You want to replicate one subset of objects. You identify the object subset by adding a filter in the rule. In the filter, you specify an object key prefix, tags, or a combination of both, to identify the subset of objects that the rule applies to. The filters target objects that match the exact values that you specify.

You add multiple rules in a replication configuration if you want to replicate different subsets of objects. In each rule, you specify a filter that selects a different subset of objects. For example, you might choose to replicate objects that have either tax/ or document/ key prefixes. To do this, you add two rules, one that specifies the tax/ key prefix filter and another that specifies the document/ key prefix. For more information about object key prefix, see [Organizing objects using prefixes](#).

The following sections provide additional information.

Topics

- [Basic rule configuration](#)
- [Optional: Specifying a filter](#)
- [Additional destination configurations](#)
- [Example replication configurations](#)
- [Backward compatibility](#)

Basic rule configuration

Each rule must include the rule's status and priority. The rule must also indicate whether to replicate delete markers.

- Status indicates whether the rule is enabled or disabled by using the values Enabled or Disabled. If a rule is disabled, Amazon S3 doesn't perform the actions specified in the rule.
- Priority indicates which rule has precedence whenever two or more replication rules conflict. Amazon S3 attempts to replicate objects according to all replication rules. However, if there are

two or more rules with the same destination bucket, then objects are replicated according to the rule with the highest priority. The higher the number, the higher the priority.

- `DeleteMarkerReplication` indicates whether to replicate delete markers by using the values `Enabled` or `Disabled`.

In the destination configuration, you must provide the name of the bucket or buckets where you want Amazon S3 to replicate objects.

The following example shows the minimum requirements for a V2 rule. For backward compatibility, Amazon S3 continues to support the XML V1 format. For more information, see [Backward compatibility](#).

```
...
<Rule>
  <ID>Rule-1</ID>
  <Status>Enabled-or-Disabled</Status>
  <Filter>
    <Prefix></Prefix>
  </Filter>
  <Priority>integer</Priority>
  <DeleteMarkerReplication>
    <Status>Enabled-or-Disabled</Status>
  </DeleteMarkerReplication>
  <Destination>
    <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket>
  </Destination>
</Rule>
<Rule>
  ...
</Rule>
  ...
...
...
```

You can also specify other configuration options. For example, you might choose to use a storage class for object replicas that differs from the class for the source object.

Optional: Specifying a filter

To choose a subset of objects that the rule applies to, add an optional filter. You can filter by object key prefix, object tags, or a combination of both. If you filter on both a key prefix and object tags,

Amazon S3 combines the filters by using a logical AND operator. In other words, the rule applies to a subset of objects with a specific key prefix and specific tags.

Filter based on object key prefix

To specify a rule with a filter based on an object key prefix, use the following code. You can specify only one prefix.

```
<Rule>
  ...
  <Filter>
    <Prefix>key-prefix</Prefix>
  </Filter>
  ...
</Rule>
...
```

Filter based on object tags

To specify a rule with a filter based on object tags, use the following code. You can specify one or more object tags.

```
<Rule>
  ...
  <Filter>
    <And>
      <Tag>
        <Key>key1</Key>
        <Value>value1</Value>
      </Tag>
      <Tag>
        <Key>key2</Key>
        <Value>value2</Value>
      </Tag>
      ...
    </And>
  </Filter>
  ...
</Rule>
...
```

Filter with a key prefix and object tags

To specify a rule filter with a combination of a key prefix and object tags, use the following code. You wrap these filters in an And parent element. Amazon S3 performs a logical AND operation to combine these filters. In other words, the rule applies to a subset of objects with both a specific key prefix and specific tags.

```
<Rule>
  ...
  <Filter>
    <And>
      <Prefix>key-prefix</Prefix>
      <Tag>
        <Key>key1</Key>
        <Value>value1</Value>
      </Tag>
      <Tag>
        <Key>key2</Key>
        <Value>value2</Value>
      </Tag>
      ...
    </And>
  </Filter>
  ...
</Rule>
...
```

Note

If you specify a rule with an empty filter tag, your rule applies to all objects in your bucket.

Additional destination configurations

In the destination configuration, you specify the bucket or buckets where you want Amazon S3 to replicate objects. You can set configurations to replicate objects from one source bucket to one or more destination buckets.

```
...
<Destination>
  <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket>
</Destination>
...
```

You can add the following options in the <Destination> element.

Topics

- [Specify storage class](#)
- [Add multiple destination buckets](#)
- [Specify different parameters for each replication rule with multiple destination buckets](#)
- [Change replica ownership](#)
- [Enable S3 Replication Time Control](#)
- [Replicate objects created with server-side encryption by using AWS KMS](#)

Specify storage class

You can specify the storage class for the object replicas. By default, Amazon S3 uses the storage class of the source object to create object replicas, as in the following example.

```
...
<Destination>
    <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket>
    <StorageClass>storage-class</StorageClass>
</Destination>
...
```

Add multiple destination buckets

You can add multiple destination buckets in a single replication configuration, as follows.

```
...
<Rule>
    <ID>Rule-1</ID>
    <Status>Enabled-or-Disabled</Status>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
        <Status>Enabled-or-Disabled</Status>
    </DeleteMarkerReplication>
    <Destination>
        <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET1</Bucket>
    </Destination>
</Rule>
<Rule>
```

```
<ID>Rule-2</ID>
<Status>Enabled-or-Disabled</Status>
<Priority>integer</Priority>
<DeleteMarkerReplication>
    <Status>Enabled-or-Disabled</Status>
</DeleteMarkerReplication>
<Destination>
    <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET2</Bucket>
</Destination>
</Rule>
...
...
```

Specify different parameters for each replication rule with multiple destination buckets

When adding multiple destination buckets in a single replication configuration, you can specify different parameters for each replication rule, as follows.

```
...
<Rule>
    <ID>Rule-1</ID>
    <Status>Enabled-or-Disabled</Status>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
        <Status>Disabled</Status>
    </DeleteMarkerReplication>
    <Metrics>
        <Status>Enabled</Status>
        <EventThreshold>
            <Minutes>15</Minutes>
        </EventThreshold>
    </Metrics>
    <Destination>
        <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET1</Bucket>
    </Destination>
</Rule>
<Rule>
    <ID>Rule-2</ID>
    <Status>Enabled-or-Disabled</Status>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
        <Status>Enabled</Status>
    </DeleteMarkerReplication>
    <Metrics>
```

```
<Status>Enabled</Status>
<EventThreshold>
  <Minutes>15</Minutes>
</EventThreshold>
</Metrics>
<ReplicationTime>
  <Status>Enabled</Status>
  <Time>
    <Minutes>15</Minutes>
  </Time>
</ReplicationTime>
<Destination>
  <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET2</Bucket>
</Destination>
</Rule>
...
...
```

Change replica ownership

When the source and destination buckets aren't owned by the same accounts, you can change the ownership of the replica to the AWS account that owns the destination bucket. To do so, add the `AccessControlTranslation` element. This element takes the value `Destination`.

```
...
<Destination>
  <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket>
  <Account>destination-bucket-owner-account-id</Account>
  <AccessControlTranslation>
    <Owner>Destination</Owner>
  </AccessControlTranslation>
</Destination>
...
...
```

If you don't add the `AccessControlTranslation` element to the replication configuration, the replicas are owned by the same AWS account that owns the source object. For more information, see [Changing the replica owner](#).

Enable S3 Replication Time Control

You can enable S3 Replication Time Control (S3 RTC) in your replication configuration. S3 RTC replicates most objects in seconds and 99.99 percent of objects within 15 minutes (backed by a service-level agreement).

Note

Only a value of <Minutes>15</Minutes> is accepted for EventThreshold and Time.

```
...
<Destination>
  <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket>
  <Metrics>
    <Status>Enabled</Status>
    <EventThreshold>
      <Minutes>15</Minutes>
    </EventThreshold>
  </Metrics>
  <ReplicationTime>
    <Status>Enabled</Status>
    <Time>
      <Minutes>15</Minutes>
    </Time>
  </ReplicationTime>
</Destination>
...
```

For more information, see [Meeting compliance requirements using S3 Replication Time Control \(S3 RTC\)](#). For API examples, see [PutBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

Replicate objects created with server-side encryption by using AWS KMS

Your source bucket might contain objects that were created with server-side encryption by using AWS Key Management Service (AWS KMS) keys (SSE-KMS). By default, Amazon S3 doesn't replicate these objects. You can optionally direct Amazon S3 to replicate these objects. To do so, first explicitly opt into this feature by adding the SourceSelectionCriteria element. Then provide the AWS KMS key (for the AWS Region of the destination bucket) to use for encrypting object replicas. The following example shows how to specify these elements.

```
...
<SourceSelectionCriteria>
  <SseKmsEncryptedObjects>
    <Status>Enabled</Status>
  </SseKmsEncryptedObjects>
```

```
</SourceSelectionCriteria>
<Destination>
  <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket>
  <EncryptionConfiguration>
    <ReplicaKmsKeyID>AWS KMS key ID to use for encrypting object replicas</ReplicaKmsKeyID>
  </EncryptionConfiguration>
</Destination>
...
...
```

For more information, see [Replicating objects created with server-side encryption \(SSE-C, SSE-S3, SSE-KMS, DSSE-KMS\)](#).

Example replication configurations

To get started, you can add the following example replication configurations to your bucket, as appropriate.

Important

To add a replication configuration to a bucket, you must have the `iam:PassRole` permission. This permission allows you to pass the IAM role that grants Amazon S3 replication permissions. You specify the IAM role by providing the Amazon Resource Name (ARN) that is used in the `Role` element in the replication configuration XML. For more information, see [Granting a User Permissions to Pass a Role to an AWS service](#) in the *IAM User Guide*.

Example 1: Replication configuration with one rule

The following basic replication configuration specifies one rule. The rule specifies an IAM role that Amazon S3 can assume and a single destination bucket for object replicas. The `Status` value of `Enabled` indicates that the rule is in effect.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Destination><Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket></Destination>
```

```
</Rule>
</ReplicationConfiguration>
```

To choose a subset of objects to replicate, you can add a filter. In the following configuration, the filter specifies an object key prefix. This rule applies to objects that have the prefix *Tax/* in their key names.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>

    <Filter>
      <Prefix>Tax/</Prefix>
    </Filter>

    <Destination><Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket></Destination>

  </Rule>
</ReplicationConfiguration>
```

If you specify the `Filter` element, you must also include the `Priority` and `DeleteMarkerReplication` elements. In this example, `Priority` is irrelevant because there is only one rule.

In the following configuration, the filter specifies one prefix and two tags. The rule applies to the subset of objects that have the specified key prefix and tags. Specifically, it applies to object that have the *Tax/* prefix in their key names and the two specified object tags. `Priority` doesn't apply because there is only one rule.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
```

```
<Priority>1</Priority>
<DeleteMarkerReplication>
  <Status>string</Status>
</DeleteMarkerReplication>

<Filter>
  <And>
    <Prefix>Tax/</Prefix>
    <Tag>
      <Tag>
        <Key>tagA</Key>
        <Value>valueA</Value>
      </Tag>
    </Tag>
    <Tag>
      <Tag>
        <Key>tagB</Key>
        <Value>valueB</Value>
      </Tag>
    </Tag>
  </And>

</Filter>

<Destination><Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket></Destination>

</Rule>
</ReplicationConfiguration>
```

You can specify a storage class for the object replicas as follows.

```
<?xml version="1.0" encoding="UTF-8"?>

<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Destination>
      <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket>
      <StorageClass>storage-class</StorageClass>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

You can specify any storage class that Amazon S3 supports.

Example 2: Replication configuration with two rules

Example

In the following replication configuration:

- Each rule filters on a different key prefix so that each rule applies to a distinct subset of objects. In this example, Amazon S3 replicates objects with the key names *Tax/doc1.pdf* and *Project/project1.txt*, but it doesn't replicate objects with the key name *PersonalDoc/documentA*.
- Rule priority is irrelevant because the rules apply to two distinct sets of objects. The next example shows what happens when rule priority is applied.
- The second rule specifies the S3 Standard-IA storage class for object replicas. Amazon S3 uses the specified storage class for those object replicas.

```
<?xml version="1.0" encoding="UTF-8"?>

<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Destination>
      <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET1</Bucket>
    </Destination>
    ...
  </Rule>
  <Rule>
    <Status>Enabled</Status>
    <Priority>2</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>
  </Rule>
</ReplicationConfiguration>
```

```
</DeleteMarkerReplication>
<Filter>
  <Prefix>Project</Prefix>
</Filter>
<Status>Enabled</Status>
<Destination>
  <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET1</Bucket>
  <StorageClass>STANDARD_IA</StorageClass>
</Destination>
...
</Rule>

</ReplicationConfiguration>
```

Example 3: Replication configuration with two rules with overlapping prefixes

In this configuration, the two rules specify filters with overlapping key prefixes, *star/* and *starship/*. Both rules apply to objects with the key name *starship-x*. In this case, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority.

```
<ReplicationConfiguration>

<Role>arn:aws:iam::account-id:role/role-name</Role>

<Rule>
  <Status>Enabled</Status>
  <Priority>1</Priority>
  <DeleteMarkerReplication>
    <Status>string</Status>
  </DeleteMarkerReplication>
  <Filter>
    <Prefix>star</Prefix>
  </Filter>
  <Destination>
    <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET1</Bucket>
  </Destination>
</Rule>
<Rule>
  <Status>Enabled</Status>
  <Priority>2</Priority>
  <DeleteMarkerReplication>
```

```
<Status>string</Status>
</DeleteMarkerReplication>
<Filter>
  <Prefix>starship</Prefix>
</Filter>
<Destination>
  <Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET1</Bucket>
</Destination>
</Rule>
</ReplicationConfiguration>
```

Example 4: Example walkthroughs

For example walkthroughs, see [Walkthroughs: Examples for configuring replication](#).

For more information about the XML structure of replication configuration, see [PutBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

Backward compatibility

The latest version of the replication configuration XML is V2. XML V2 replication configurations are those that contain the `Filter` element for rules, and rules that specify S3 Replication Time Control (S3 RTC).

To see your replication configuration version, you can use the `GetBucketReplication` API operation. For more information, see [GetBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

For backward compatibility, Amazon S3 continues to support the XML V1 replication configuration. If you've used XML V1 replication configuration, consider the following issues that affect backward compatibility:

- Replication configuration XML V2 includes the `Filter` element for rules. With the `Filter` element, you can specify object filters based on the object key prefix, tags, or both to scope the objects that the rule applies to. Replication configuration XML V1 supports filtering based only on the key prefix. In that case, you add the `Prefix` directly as a child element of the `Rule` element, as in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
```

```
<Status>Enabled</Status>
<Prefix>key-prefix</Prefix>
<Destination><Bucket>arn:aws:s3:::DOC-EXAMPLE-BUCKET</Bucket></Destination>

</Rule>
</ReplicationConfiguration>
```

For backward compatibility, Amazon S3 continues to support the V1 configuration.

- When you delete an object from your source bucket without specifying an object version ID, Amazon S3 adds a delete marker. If you use V1 of the replication configuration XML, Amazon S3 replicates delete markers that result from user actions. In other words, Amazon S3 replicates the delete marker only if a user deletes an object. If an expired object is removed by Amazon S3 (as part of a lifecycle action), Amazon S3 does not replicate the delete marker.

In V2 replication configurations, you can enable delete marker replication for non-tag-based rules. For more information, see [Replicating delete markers between buckets](#).

Setting up permissions

When setting up replication, you must acquire the necessary permissions as follows:

- Amazon S3 needs permissions to replicate objects on your behalf. You grant these permissions by creating an IAM role and then specifying that role in your replication configuration.
- When the source and destination buckets aren't owned by the same accounts, the owner of the destination bucket must grant the source bucket owner permissions to store the replicas.

Topics

- [Creating an IAM role](#)
- [Granting permissions when the source and destination buckets are owned by different AWS accounts](#)
- [Granting permissions for S3 Batch Operations](#)
- [Changing replica ownership](#)
- [Enable receiving replicated objects from a source bucket](#)

Creating an IAM role

By default, all Amazon S3 resources—buckets, objects, and related subresources—are private, and only the resource owner can access the resource. Amazon S3 needs permissions to read and replicate objects from the source bucket. You grant these permissions by creating an IAM role and specifying the role in your replication configuration.

This section explains the trust policy and minimum required permissions policy. The example walkthroughs provide step-by-step instructions to create an IAM role. For more information, see [Walkthroughs: Examples for configuring replication](#).

- The following example shows a *trust policy*, where you identify Amazon S3 as the service principal who can assume the role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- The following example shows a *trust policy*, where you identify Amazon S3 and S3 Batch Operations as service principals. This is useful if you are creating a Batch Replication job. For more information, see [Create a Batch Replication job for a first replication rule or new destination](#).

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": [  
                    "s3.amazonaws.com",  
                    "batchoperations.s3.amazonaws.com"  
                ]  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

```
        "Action":"sts:AssumeRole"
    }
]
}
```

For more information about IAM roles, see [IAM Roles](#) in the *IAM User Guide*.

- The following example shows an *access policy*, where you grant the role permissions to perform replication tasks on your behalf. When Amazon S3 assumes the role, it has the permissions that you specify in this policy. In this policy, *DOC-EXAMPLE-BUCKET1* is the source bucket, and *DOC-EXAMPLE-BUCKET2* is the destination bucket.

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action": [
                "s3:GetReplicationConfiguration",
                "s3>ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-BUCKET1"
            ]
        },
        {
            "Effect":"Allow",
            "Action": [
                "s3:GetObjectVersionForReplication",
                "s3:GetObjectVersionAcl",
                "s3:GetObjectVersionTagging"
            ],
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-BUCKET1/*"
            ]
        },
        {
            "Effect":"Allow",
            "Action": [
                "s3:ReplicateObject",
                "s3:ReplicateDelete",
                "s3:ReplicateTags"
            ],
        }
    ]
}
```

```
        "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET2/*"
    }
]
}
```

The access policy grants permissions for the following actions:

- s3:GetReplicationConfiguration and s3>ListBucket – Permissions for these actions on the *DOC-EXAMPLE-BUCKET1* bucket (the source bucket) allow Amazon S3 to retrieve the replication configuration and list the bucket content. (The current permissions model requires the s3>ListBucket permission for accessing delete markers.)
- s3:GetObjectVersionForReplication and s3:GetObjectVersionAcl – Permissions for these actions are granted on all objects to allow Amazon S3 to get a specific object version and access control list (ACL) associated with the objects.
- s3:ReplicateObject and s3:ReplicateDelete – Permissions for these actions on all objects in the *DOC-EXAMPLE-BUCKET2* bucket (the destination bucket) allow Amazon S3 to replicate objects or delete markers to the destination bucket. For information about delete markers, see [How delete operations affect replication](#).

 **Note**

Permissions for the s3:ReplicateObject action on the *DOC-EXAMPLE-BUCKET2* bucket (the destination bucket) also allow replication of metadata such as object tags and ACLs. Therefore you do not need to explicitly grant permission for the s3:ReplicateTags action.

- s3:GetObjectVersionTagging – Permissions for this action on objects in the *DOC-EXAMPLE-BUCKET1* bucket (the source bucket) allow Amazon S3 to read object tags for replication. For more information, see [Categorizing your storage using tags](#). If Amazon S3 doesn't have these permissions, it replicates the objects, but not the object tags.

For a list of Amazon S3 actions, see [Amazon S3 actions](#).

 **Important**

The AWS account that owns the IAM role must have permissions for the actions that it grants to the IAM role.

For example, suppose that the source bucket contains objects owned by another AWS account. The owner of the objects must explicitly grant the AWS account that owns the IAM role the required permissions through the object ACL. Otherwise, Amazon S3 can't access the objects, and replication of the objects fails. For information about ACL permissions, see [Access control list \(ACL\) overview](#).

The permissions described here are related to the minimum replication configuration. If you choose to add optional replication configurations, you must grant additional permissions to Amazon S3. For more information, see [Additional replication configurations](#).

Granting permissions when the source and destination buckets are owned by different AWS accounts

When the source and destination buckets aren't owned by the same accounts, the owner of the destination bucket must also add a bucket policy to grant the owner of the source bucket permissions to perform replication actions, as follows. In this policy, `DOC-EXAMPLE-BUCKET2` is the destination bucket.

 Note

The ARN format of the role may appear different. If the role was created using the console, the ARN format is `arn:aws:iam::account-ID:role/service-role/role-name`. If the role was created using the AWS CLI, the ARN format is `arn:aws:iam::account-ID:role/role-name`. For more information, see [IAM Roles](#) in the *IAM User Guide*.

```
        "s3:ReplicateDelete",
        "s3:ReplicateObject"
    ],
    "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET2/*"
},
{
    "Sid": "Permissions on bucket",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::SourceBucket-account-ID:role/service-role/source-account-IAM-role"
    },
    "Action": [
        "s3>List*",
        "s3:GetBucketVersioning",
        "s3:PutBucketVersioning"
    ],
    "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET2"
}
]
}
```

For an example, see [Configuring replication when source and destination buckets are owned by different accounts](#).

If objects in the source bucket are tagged, note the following:

- If the source bucket owner grants Amazon S3 permission for the `s3:GetObjectVersionTagging` and `s3:ReplicateTags` actions to replicate object tags (through the IAM role), Amazon S3 replicates the tags along with the objects. For information about the IAM role, see [Creating an IAM role](#).
- If the owner of the destination bucket doesn't want to replicate the tags, they can add the following statement to the destination bucket policy to explicitly deny permission for the `s3:ReplicateTags` action. In this policy, `DOC-EXAMPLE-BUCKET2` is the destination bucket.

```
...
"Statement": [
{
    "Effect": "Deny",
    "Principal": {
        "AWS": "arn:aws:iam::SourceBucket-account-id:role/service-role/source-account-IAM-role"
    }
}
```

```
    },
    "Action":"s3:ReplicateTags",
    "Resource":"arn:aws:s3:::DOC-EXAMPLE-BUCKET2/*"
}
]
...
...
```

Granting permissions for S3 Batch Operations

S3 Batch Replication provides you a way to replicate objects that existed before a replication configuration was in place, objects that have previously been replicated, and objects that have failed replication. You may create a one-time Batch Replication job when creating the first rule in a new replication configuration or when adding a new destination to an existing configuration through the AWS Management Console. You may also initiate Batch Replication for an existing replication configuration by creating a Batch Operations job.

For Batch Replication IAM role and policy examples see, [Configuring IAM policies for Batch Replication](#).

Changing replica ownership

When different AWS accounts own the source and destination buckets, you can tell Amazon S3 to change the ownership of the replica to the AWS account that owns the destination bucket. For more information about owner override, see [Changing the replica owner](#).

Enable receiving replicated objects from a source bucket

You can quickly generate the policies needed to enable receiving replicated objects from a source bucket through the AWS Management Console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to use as a destination bucket.
4. Choose the **Management** tab, and scroll down to **Replication rules**.
5. For **Actions**, choose **Receive replicated objects**.

Follow the prompts and enter the AWS account ID of the source bucket account and choose **Generate policies**. This will generate an Amazon S3 bucket policy and a KMS key policy.

6. To add this policy to your existing bucket policy, either choose **Apply settings** or choose **Copy** to manually copy the changes.
7. (Optional) Copy the AWS KMS policy to your desired KMS key policy on the AWS Key Management Service console.

Walkthroughs: Examples for configuring replication

The following examples show how to configure live replication for common use cases. The examples demonstrate replication configuration using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDKs (Java and .NET SDK examples are shown). For information about installing and configuring the AWS CLI, see the following topics in the *AWS Command Line Interface User Guide*.

 **Note**

Live replication refers to Same-Region Replication (SRR) and Cross-Region Replication (CRR). For an on-demand replication action to sync buckets and replicate existing objects, see [Replicate existing objects](#).

- [Installing the AWS Command Line Interface](#)
- [Configuring the AWS CLI](#) – You must set up at least one profile. If you are exploring cross-account scenarios, set up two profiles.

For information about AWS SDKs, see [AWS SDK for Java](#) and [AWS SDK for .NET](#).

To learn more about how to use S3 Replication to replicate data, see [Tutorial: Replicating data within and between AWS Regions using S3 Replication](#).

Topics

- [Configuring replication for source and destination buckets owned by the same account](#)
- [Configuring replication when source and destination buckets are owned by different accounts](#)
- [Changing the replica owner when source and destination buckets are owned by different accounts](#)
- [Replicating encrypted objects](#)
- [Replicating objects with S3 Replication Time Control \(S3 RTC\)](#)

- [Managing replication rules using the Amazon S3 console](#)

Configuring replication for source and destination buckets owned by the same account

Replication is the automatic, asynchronous copying of objects across buckets in the same or different AWS Regions. Replication copies newly created objects and object updates from a source bucket to a destination bucket or buckets. For more information, see [Replicating objects](#).

When you configure replication, you add replication rules to the source bucket. Replication rules define which source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. You can create a rule to replicate all the objects in a bucket or a subset of objects with a specific key name prefix, one or more object tags, or both. A destination bucket can be in the same AWS account as the source bucket, or it can be in a different account.

If you specify an object version ID to delete, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination bucket. In other words, it doesn't delete the same object version from the destination bucket. This protects data from malicious deletions.

When you add a replication rule to a bucket, the rule is enabled by default, so it starts working as soon as you save it.

In this example, you set up replication for source and destination buckets that are owned by the same AWS account. Examples are provided for using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), and the AWS SDK for Java and AWS SDK for .NET.

Using the S3 console

To configure a replication rule when the destination bucket is in the same AWS account as the source bucket, follow these steps.

If the destination bucket is in a different account from the source bucket, you must add a bucket policy to the destination bucket to grant the owner of the source bucket account permission to replicate objects in the destination bucket. For more information, see [Granting permissions when the source and destination buckets are owned by different AWS accounts](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.

3. In the **Buckets** list, choose the name of the bucket that you want.
4. Choose the **Management** tab, scroll down to **Replication rules**, and then choose **Create replication rule**.
5. In the **Replication rule configuration** section, under **Replication rule name**, enter a name for your rule to help identify the rule later. The name is required and must be unique within the bucket.
6. Under **Status**, **Enabled** is selected by default. An enabled rule starts to work as soon as you save it. If you want to enable the rule later, choose **Disabled**.
7. If the bucket has existing replication rules, you are instructed to set a priority for the rule. You must set a priority for the rule to avoid conflicts caused by objects that are included in the scope of more than one rule. In the case of overlapping rules, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority. For more information about rule priority, see [Replication configuration](#).
8. Under **Source bucket**, you have the following options for setting the replication source:
 - To replicate the whole bucket, choose **Apply to all objects in the bucket**.
 - To replicate all objects that have the same prefix, choose **Limit the scope of this rule using one or more filters**. This limits replication to all objects that have names that begin with the prefix that you specify (for example pictures). Enter a prefix in the **Prefix** box.

 **Note**

If you enter a prefix that is the name of a folder, you must use / (forward slash) as the last character (for example, pictures/).

- To replicate all objects with one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. Repeat the procedure to add another tag. You can combine a prefix and tags. For more information about object tags, see [Categorizing your storage using tags](#).

The new replication configuration XML schema supports prefix and tag filtering and the prioritization of rules. For more information about the new schema, see [Backward compatibility](#). For more information about the XML used with the Amazon S3 API that works behind the user interface, see [Replication configuration](#). The new schema is described as *replication configuration XML V2*.

9. Under **Destination**, choose the bucket where you want Amazon S3 to replicate objects.

Note

The number of destination buckets is limited to the number of AWS Regions in a given partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (Standard Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US) Regions). To request an increase in your destination bucket quota, you can use [service quotas](#).

- To replicate to a bucket or buckets in your account, choose **Choose a bucket in this account**, and enter or browse for the destination bucket names.
- To replicate to a bucket or buckets in a different AWS account, choose **Specify a bucket in another account**, and enter the destination bucket account ID and bucket name.

If the destination is in a different account from the source bucket, you must add a bucket policy to the destination buckets to grant the owner of the source bucket account permission to replicate objects. For more information, see [Granting permissions when the source and destination buckets are owned by different AWS accounts](#).

Optionally, if you want to help standardize ownership of new objects in the destination bucket, choose **Change object ownership to the destination bucket owner**. For more information about this option, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Note

If versioning is not enabled on the destination bucket, you get a warning that contains an **Enable versioning** button. Choose this button to enable versioning on the bucket.

10. Set up an AWS Identity and Access Management (IAM) role that Amazon S3 can assume to replicate objects on your behalf.

To set up an IAM role, in the **IAM role** section, select one of the following from the **IAM role** dropdown list:

- We highly recommend that you choose **Create new role** to have Amazon S3 create a new IAM role for you. When you save the rule, a new policy is generated for the IAM role that matches the source and destination buckets that you choose.
- You can choose to use an existing IAM role. If you do, you must choose a role that grants Amazon S3 the necessary permissions for replication. Replication fails if this role does not grant Amazon S3 sufficient permissions to follow your replication rule.

 **Important**

When you add a replication rule to a bucket, you must have the `iam:PassRole` permission to be able to pass the IAM role that grants Amazon S3 replication permissions. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

11. To replicate objects in the source bucket that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), under **Encryption**, select **Replicate objects encrypted with AWS KMS**. Under **AWS KMS keys for encrypting destination objects** are the source keys that you allow replication to use. All source KMS keys are included by default. To narrow the KMS key selection, you can choose an alias or key ID.

Objects encrypted by AWS KMS keys that you do not select are not replicated. A KMS key or a group of KMS keys is chosen for you, but you can choose the KMS keys if you want. For information about using AWS KMS with replication, see [Replicating objects created with server-side encryption \(SSE-C, SSE-S3, SSE-KMS, DSSE-KMS\)](#).

 **Important**

When you replicate objects that are encrypted with AWS KMS, the AWS KMS request rate doubles in the source Region and increases in the destination Region by the same amount. These increased call rates to AWS KMS are due to the way that data is re-encrypted by using the KMS key that you define for the replication destination Region. AWS KMS has a request rate quota that is per calling account per Region. For information about the quota defaults, see [AWS KMS Quotas - Requests per Second: Varies in the AWS Key Management Service Developer Guide](#).

If your current Amazon S3 PUT object request rate during replication is more than half the default AWS KMS rate limit for your account, we recommend that you request an

increase to your AWS KMS request rate quota. To request an increase, create a case in the AWS Support Center at [Contact Us](#). For example, suppose that your current PUT object request rate is 1,000 requests per second and you use AWS KMS to encrypt your objects. In this case, we recommend that you ask AWS Support to increase your AWS KMS rate limit to 2,500 requests per second, in both your source and destination Regions (if different), to ensure that there is no throttling by AWS KMS.

To see your PUT object request rate in the source bucket, view PutRequests in the Amazon CloudWatch request metrics for Amazon S3. For information about viewing CloudWatch metrics, see [Using the S3 console](#)

If you chose to replicate objects encrypted with AWS KMS, do the following:

- Under **AWS KMS key for encrypting destination objects**, specify your KMS key in one of the following ways:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key Amazon Resource Name (ARN), choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears. This encrypts the replicas in the destination bucket. You can find the ARN for your KMS key in the [IAM Console](#), under **Encryption keys**.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

Important

You can only use KMS keys that are enabled in the same AWS Region as the bucket. When you choose **Choose from your KMS keys**, the S3 console lists only 100 KMS keys per Region. If you have more than 100 KMS keys in the same

Region, you can see only the first 100 KMS keys in the S3 console. To use a KMS key that is not listed in the console, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN.

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*. For more information about using AWS KMS with Amazon S3, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

12. Under **Destination storage class**, if you want to replicate your data into a specific storage class in the destination, choose **Change the storage class for the replicated objects**. Then choose the storage class that you want to use for the replicated objects in the destination. If you don't choose this option, the storage class for replicated objects is the same class as the original objects.
13. You have the following additional options while setting the **Additional replication options**:
 - If you want to enable S3 Replication Time Control (S3 RTC) in your replication configuration, select **Replication Time Control (RTC)**. For more information about this option, see [Meeting compliance requirements using S3 Replication Time Control \(S3 RTC\)](#).
 - If you want to enable S3 Replication metrics in your replication configuration, select **Replication metrics and events**. For more information see, [Monitoring progress with replication metrics and S3 Event Notifications](#).
 - If you want to enable delete marker replication in your replication configuration, select **Delete marker replication**. For more information see, [Replicating delete markers between buckets](#).
 - If you want to enable Amazon S3 replica modification sync in your replication configuration, select **Replica modification sync**. For more information see, [Replicating metadata changes with Amazon S3 replica modification sync](#).

Note

When you use S3 RTC or S3 Replication metrics, additional fees apply.

14. To finish, choose **Save**.
15. After you save your rule, you can edit, enable, disable, or delete your rule by selecting your rule and choosing **Edit rule**.

Using the AWS CLI

To use the AWS CLI to set up replication when the source and destination buckets are owned by the same AWS account, you do the following:

- Create source and destination buckets
- Enable versioning on the buckets
- Create an IAM role that gives Amazon S3 permission to replicate objects
- Add the replication configuration to the source bucket

To verify your setup, you test it.

To set up replication when source and destination buckets are owned by the same AWS account

1. Set a credentials profile for the AWS CLI. In this example, we use the profile name acctA. For information about setting credential profiles, see [Named Profiles](#) in the *AWS Command Line Interface User Guide*.

⚠ Important

The profile you use for this exercise must have the necessary permissions. For example, in the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if the profile you use has the `iam:PassRole` permission. For more information, see [Granting a User Permissions to Pass a Role to an AWS Service](#) in the *IAM User Guide*. If you use administrator credentials to create a named profile, you can perform all the tasks.

2. Create a *source* bucket and enable versioning on it. The following code creates a *source* bucket in the US East (N. Virginia) (us-east-1) Region.

```
aws s3api create-bucket \  
--bucket source \  
--region us-east-1 \  
--profile acctA
```

```
aws s3api put-bucket-versioning \  
--bucket source \  
--versioning-configuration Status=Enabled \  
--profile acctA
```

3. Create a *destination* bucket and enable versioning on it. The following code creates a *destination* bucket in the US West (Oregon) (us-west-2) Region.

 **Note**

To set up replication configuration when both source and destination buckets are in the same AWS account, you use the same profile. This example uses acctA. To test replication configuration when the buckets are owned by different AWS accounts, you specify different profiles for each. This example uses the acctB profile for the destination bucket.

```
aws s3api create-bucket \  
--bucket destination \  
--region us-west-2 \  
--create-bucket-configuration LocationConstraint=us-west-2 \  
--profile acctA
```

```
aws s3api put-bucket-versioning \  
--bucket destination \  
--versioning-configuration Status=Enabled \  
--profile acctA
```

4. Create an IAM role. You specify this role in the replication configuration that you add to the *source* bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create a role.
- Attach a permissions policy to the role.

a. Create the IAM role.

- i. Copy the following trust policy and save it to a file named `s3-role-trust-policy.json` in the current directory on your local computer. This policy grants Amazon S3 service principal permissions to assume the role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- ii. Run the following command to create a role.

```
$ aws iam create-role \  
--role-name replicationRole \  
--assume-role-policy-document file://s3-role-trust-policy.json \  
--profile acctA
```

b. Attach a permissions policy to the role.

- i. Copy the following permissions policy and save it to a file named `s3-role-permissions-policy.json` in the current directory on your local computer. This policy grants permissions for various Amazon S3 bucket and object actions.

```
{  
    "Version": "2012-10-17",
```

```
"Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "s3:GetObjectVersionForReplication",
            "s3:GetObjectVersionAcl",
            "s3:GetObjectVersionTagging"
        ],
        "Resource": [
            "arn:aws:s3:::source-bucket/*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3>ListBucket",
            "s3:GetReplicationConfiguration"
        ],
        "Resource": [
            "arn:aws:s3:::source-bucket"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:ReplicateObject",
            "s3:ReplicateDelete",
            "s3:ReplicateTags"
        ],
        "Resource": "arn:aws:s3:::destination-bucket/*"
    }
]
```

- ii. Run the following command to create a policy and attach it to the role.

```
$ aws iam put-role-policy \
--role-name replicationRole \
--policy-document file://s3-role-permissions-policy.json \
--policy-name replicationRolePolicy \
--profile acctA
```

5. Add replication configuration to the *source* bucket.

- a. Although the Amazon S3 API requires replication configuration as XML, the AWS CLI requires that you specify the replication configuration as JSON. Save the following JSON in a file called `replication.json` to the local directory on your computer.

```
{  
    "Role": "IAM-role-ARN",  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Priority": 1,  
            "DeleteMarkerReplication": { "Status": "Disabled" },  
            "Filter" : { "Prefix": "Tax"},  
            "Destination": {  
                "Bucket": "arn:aws:s3:::destination-bucket"  
            }  
        }  
    ]  
}
```

- b. Update the JSON by providing values for the `destination-bucket` and `IAM-role-ARN`. Save the changes.
- c. Run the following command to add the replication configuration to your source bucket. Be sure to provide the `source` bucket name.

```
$ aws s3api put-bucket-replication \  
--replication-configuration file://replication.json \  
--bucket source \  
--profile acctA
```

To retrieve the replication configuration, use the `get-bucket-replication` command.

```
$ aws s3api get-bucket-replication \  
--bucket source \  
--profile acctA
```

6. Test the setup in the Amazon S3 console:

- a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

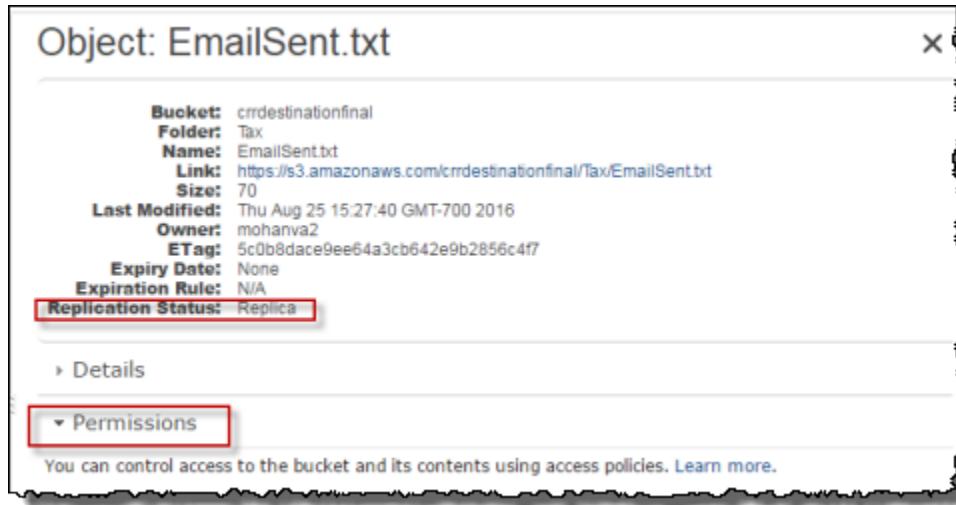

- b. In the **source** bucket, create a folder named Tax.
- c. Add sample objects to the Tax folder in the **source** bucket.

 **Note**

The amount of time it takes for Amazon S3 to replicate an object depends on the size of the object. For information about how to see the status of replication, see [Getting replication status information](#).

In the **destination** bucket, verify the following:

- That Amazon S3 replicated the objects.
- In object **properties**, that the **Replication Status** is set to Replica (identifying this as a replica object).
- In object **properties**, that the permission section shows no permissions. This means that the replica is still owned by the **source** bucket owner, and the **destination** bucket owner has no permission on the object replica. You can add optional configuration to tell Amazon S3 to change the replica ownership. For an example, see [Changing the replica owner when source and destination buckets are owned by different accounts](#).

Using the AWS SDKs

Use the following code examples to add a replication configuration to a bucket with the AWS SDK for Java and AWS SDK for .NET, respectively.

Java

The following example adds a replication configuration to a bucket and then retrieves and verifies the configuration. For instructions on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

    iamClient.putRolePolicy(putRolePolicyRequest);

}
```

C#

The following AWS SDK for .NET code example adds a replication configuration to a bucket and then retrieves it. To use this code, provide the names for your buckets and the Amazon Resource Name (ARN) for your IAM role. For instructions on how to create and test a working sample, see [Running the Amazon S3 .NET Code Examples](#).

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CrossRegionReplicationTest
    {
        private const string sourceBucket = "*** source bucket ***";
        // Bucket ARN example - arn:aws:s3:::destinationbucket
        private const string destinationBucketArn = "*** destination bucket ARN
***";
        private const string roleArn = "*** IAM Role ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint sourceBucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        public static void Main()
        {
            s3Client = new AmazonS3Client(sourceBucketRegion);
            EnableReplicationAsync().Wait();
        }
        static async Task EnableReplicationAsync()
        {
            try
```

```
{  
    ReplicationConfiguration replConfig = new ReplicationConfiguration  
    {  
        Role = roleArn,  
        Rules =  
        {  
            new ReplicationRule  
            {  
                Prefix = "Tax",  
                Status = ReplicationRuleStatus.Enabled,  
                Destination = new ReplicationDestination  
                {  
                    BucketArn = destinationBucketArn  
                }  
            }  
        }  
    };  
  
    PutBucketReplicationRequest putRequest = new  
PutBucketReplicationRequest  
    {  
        BucketName = sourceBucket,  
        Configuration = replConfig  
    };  
  
    PutBucketReplicationResponse putResponse = await  
s3Client.PutBucketReplicationAsync(putRequest);  
  
    // Verify configuration by retrieving it.  
    await RetrieveReplicationConfigurationAsync(s3Client);  
}  
catch (AmazonS3Exception e)  
{  
    Console.WriteLine("Error encountered on server. Message:'{0}' when  
writing an object", e.Message);  
}  
catch (Exception e)  
{  
    Console.WriteLine("Unknown encountered on server. Message:'{0}' when  
writing an object", e.Message);  
}  
}  
private static async Task RetrieveReplicationConfigurationAsync(IAmazonS3  
client)
```

```
{  
    // Retrieve the configuration.  
    GetBucketReplicationRequest getRequest = new GetBucketReplicationRequest  
    {  
        BucketName = sourceBucket  
    };  
    GetBucketReplicationResponse getResponse = await  
client.GetBucketReplicationAsync(getRequest);  
    // Print.  
    Console.WriteLine("Printing replication configuration information...");  
    Console.WriteLine("Role ARN: {0}", getResponse.Configuration.Role);  
    foreach (var rule in getResponse.Configuration.Rules)  
    {  
        Console.WriteLine("ID: {0}", rule.Id);  
        Console.WriteLine("Prefix: {0}", rule.Prefix);  
        Console.WriteLine("Status: {0}", rule.Status);  
    }  
}  
}  
}
```

Configuring replication when source and destination buckets are owned by different accounts

Setting up replication when *source* and *destination* buckets are owned by different AWS accounts is similar to setting replication when both buckets are owned by the same account. The only difference is that the *destination* bucket owner must grant the *source* bucket owner permission to replicate objects by adding a bucket policy.

For more information about configuring replication using server-side encryption with AWS Key Management Service in cross-account scenarios, see [Granting additional permissions for cross-account scenarios](#).

To configure replication when the source and destination buckets are owned by different AWS accounts

1. In this example, you create *source* and *destination* buckets in two different AWS accounts. You need to have two credential profiles set for the AWS CLI (in this example, we use acctA and acctB for profile names). For more information about setting credential profiles, see [Named Profiles](#) in the *AWS Command Line Interface User Guide*.

2. Follow the step-by-step instructions in [Configuring for buckets in the same account](#) with the following changes:
 - For all AWS CLI commands related to *source* bucket activities (for creating the *source* bucket, enabling versioning, and creating the IAM role), use the acctA profile. Use the acctB profile to create the *destination* bucket.
 - Make sure that the permissions policy specifies the *source* and *destination* buckets that you created for this example.
3. In the console, add the following bucket policy on the *destination* bucket to allow the owner of the *source* bucket to replicate objects. Be sure to edit the policy by providing the AWS account ID of the *source* bucket owner and the *destination* bucket name.

 **Note**

To use the following example, replace the *user input placeholders* with your own information. Replace *DOC-EXAMPLE-BUCKET* with your destination bucket name. Replace *source-bucket-acct-ID:role/service-role/source-acct-IAM-role* with the role you are using for this replication configuration. If you created the IAM service role manually, set the role path as `role/service-role/`, as shown in the below policy example. For more information, see [IAM ARNs](#) in the *IAM User Guide*.

```
{  
    "Version": "2012-10-17",  
    "Id": "",  
    "Statement": [  
        {  
            "Sid": "Set-permissions-for-objects",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::source-bucket-acct-ID:role/service-role/source-acct-IAM-role"  
            },  
            "Action": ["s3:ReplicateObject", "s3:ReplicateDelete"],  
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"  
        },  
        {  
            "Sid": "Set permissions on bucket",  
            "Effect": "Allow",  
            "Principal": "aws:SourceIdentity",  
            "Action": "s3:PutBucketPolicy",  
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET"  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::source-bucket-acct-ID:role/service-role/source-
acct-IAM-role"
        },
        "Action": ["s3>List*", "s3:GetBucketVersioning", "s3:PutBucketVersioning"],
        "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET"
    }
]
```

Choose the bucket and add the bucket policy. For instructions, see [Adding a bucket policy by using the Amazon S3 console](#).

In replication, the owner of the source object owns the replica by default. When source and destination buckets are owned by different AWS accounts, you can add optional configuration settings to change replica ownership to the AWS account that owns the destination buckets. This includes granting the `ObjectOwnerOverrideToBucketOwner` permission. For more information, see [Changing the replica owner](#).

Changing the replica owner when source and destination buckets are owned by different accounts

When the *source* and *destination* buckets in a replication configuration are owned by different AWS accounts, you can tell Amazon S3 to change replica ownership to the AWS account that owns the *destination* bucket. This example explains how to use the Amazon S3 console and the AWS CLI to change replica ownership. For more information, see [Changing the replica owner](#).

Note

When you use S3 replication and the source and destination buckets are owned by different AWS accounts, the bucket owner of the destination bucket can disable ACLs (with the bucket owner enforced setting for Object Ownership) to change replica ownership to the AWS account that owns the destination bucket. This setting mimics the existing owner override behavior without the need of `s3:ObjectOwnerOverrideToBucketOwner` permission. This means that all objects that are replicated to the destination bucket with the bucket owner enforced setting are owned by the destination bucket owner. For more

information about Object Ownership, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

For more information about configuring replication using sever-side encryption with AWS Key Management Service in cross-account scenarios, see [Granting additional permissions for cross-account scenarios](#).

Using the S3 console

For step-by-step instructions, see [Configuring replication for source and destination buckets owned by the same account](#). This topic provides instructions for setting replication configuration when buckets are owned by same and different AWS accounts.

Using the AWS CLI

To change replica ownership using the AWS CLI, you create buckets, enable versioning on the buckets, create an IAM role that gives Amazon S3 permission to replicate objects, and add the replication configuration to the source bucket. In the replication configuration you direct Amazon S3 to change replica owner. You also test the setup.

To change replica ownership when source and destination buckets are owned by different AWS accounts (AWS CLI)

1. In this example, you create the *source* and *destination* buckets in two different AWS accounts. Configure the AWS CLI with two named profiles. This example uses profiles named acctA and acctB, respectively. For more information about setting credential profiles, see [Named Profiles](#) in the *AWS Command Line Interface User Guide*.

Important

The profiles you use for this exercise must have the necessary permissions. For example, in the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if the profile you use has the `iam:PassRole` permission. If you use administrator user credentials to create a named profile then you can perform all the tasks. For more information, see [Granting a User Permissions to Pass a Role to an AWS Service](#) in the *IAM User Guide*.

You will need to make sure these profiles have necessary permissions. For example, the replication configuration includes an IAM role that Amazon S3 can assume. The named profile you use to attach such configuration to a bucket can do so only if it has the `iam:PassRole` permission. If you specify administrator user credentials when creating these named profiles, they have all the permissions. For more information, see [Granting a User Permissions to Pass a Role to an AWS Service](#) in the *IAM User Guide*.

2. Create the `source` bucket and enable versioning. This example creates the `source` bucket in the US East (N. Virginia) (us-east-1) Region.

```
aws s3api create-bucket \
--bucket source \
--region us-east-1 \
--profile acctA
```

```
aws s3api put-bucket-versioning \
--bucket source \
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Create a `destination` bucket and enable versioning. This example creates the `destination` bucket in the US West (Oregon) (us-west-2) Region. Use an AWS account profile different from the one you used for the `source` bucket.

```
aws s3api create-bucket \
--bucket destination \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctB
```

```
aws s3api put-bucket-versioning \
--bucket destination \
--versioning-configuration Status=Enabled \
--profile acctB
```

4. You must add permissions to your `destination` bucket policy to allow changing the replica ownership.

- a. Save the following policy to `destination-bucket-policy.json`.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "destination_bucket_policy_sid",  
            "Principal": {  
                "AWS": "source-bucket-owner-account-id"  
            },  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateDelete",  
                "s3:ObjectOwnerOverrideToBucketOwner",  
                "s3:ReplicateTags",  
                "s3:GetObjectVersionTagging"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::destination/*"  
            ]  
        }  
    ]  
}
```

- b. Put the above policy to *destination* bucket:

```
aws s3api put-bucket-policy --region $ {destination_region} --  
bucket $ {destination} --policy file://destination_bucket_policy.json
```

5. Create an IAM role. You specify this role in the replication configuration that you add to the *source* bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create a role.
- Attach a permissions policy to the role.

- a. Create an IAM role.

- i. Copy the following trust policy and save it to a file named `s3-role-trust-policy.json` in the current directory on your local computer. This policy grants Amazon S3 permissions to assume the role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- ii. Run the following AWS CLI command to create a role.

```
$ aws iam create-role \  
--role-name replicationRole \  
--assume-role-policy-document file://s3-role-trust-policy.json \  
--profile acctA
```

- b. Attach a permissions policy to the role.

- i. Copy the following permissions policy and save it to a file named `s3-role-perm-pol-changeowner.json` in the current directory on your local computer. This policy grants permissions for various Amazon S3 bucket and object actions. In the following steps, you create an IAM role and attach this policy to the role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObjectVersionForReplication",  
                "s3:GetObjectVersionAcl"  
            ],  
            "Resource": [  
                "arn:aws:s3:::mybucket/*"  
            ]  
        }  
    ]  
}
```

```
        "arn:aws:s3:::source/*"
    ],
},
{
    "Effect": "Allow",
    "Action": [
        "s3>ListBucket",
        "s3:GetReplicationConfiguration"
    ],
    "Resource": [
        "arn:aws:s3:::source"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3>ReplicateObject",
        "s3>ReplicateDelete",
        "s3>ObjectOwnerOverrideToBucketOwner",
        "s3>ReplicateTags",
        "s3>GetObjectVersionTagging"
    ],
    "Resource": "arn:aws:s3:::destination/*"
}
]
}
```

- ii. To create a policy and attach it to the role, run the following command.

```
$ aws iam put-role-policy \
--role-name replicationRole \
--policy-document file://s3-role-perm-pol-changeowner.json \
--policy-name replicationRolechangeownerPolicy \
--profile acctA
```

6. Add a replication configuration to your source bucket.

- a. The AWS CLI requires specifying the replication configuration as JSON. Save the following JSON in a file named `replication.json` in the current directory on your local computer. In the configuration, the addition of `AccessControlTranslation` to indicate change in replica ownership.

{

```
"Role": "IAM-role-ARN",  
"Rules": [  
    {  
        "Status": "Enabled",  
        "Priority": 1,  
        "DeleteMarkerReplication": {  
            "Status": "Disabled"  
        },  
        "Filter": {  
        },  
        "Status": "Enabled",  
        "Destination": {  
            "Bucket": "arn:aws:s3:::destination",  
            "Account": "destination-bucket-owner-account-id",  
            "AccessControlTranslation": {  
                "Owner": "Destination"  
            }  
        }  
    }  
]
```

- b. Edit the JSON by providing values for the *destination* bucket owner account ID and *IAM-role-ARN*. Save the changes.
- c. To add the replication configuration to the source bucket, run the following command. Provide the *source* bucket name.

```
$ aws s3api put-bucket-replication \  
--replication-configuration file://replication.json \  
--bucket source \  
--profile acctA
```

7. Check replica ownership in the Amazon S3 console.

- a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- b. Add objects to the *source* bucket. Verify that the *destination* bucket contains the object replicas and that the ownership of the replicas has changed to the AWS account that owns the *destination* bucket.

Using the AWS SDKs

For a code example to add replication configuration, see [Using the AWS SDKs](#). You need to modify the replication configuration appropriately. For conceptual information, see [Changing the replica owner](#).

Replicating encrypted objects

By default, Amazon S3 doesn't replicate objects that are encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). To replicate objects encrypted with SSE-KMS or DSSE-KMS, you must modify the bucket replication configuration to tell Amazon S3 to replicate these objects. This example explains how to use the Amazon S3 console and the AWS Command Line Interface (AWS CLI) to change the bucket replication configuration to enable replicating encrypted objects.

For more information, see [Replicating objects created with server-side encryption \(SSE-C, SSE-S3, SSE-KMS, DSSE-KMS\)](#).

Note

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket's Amazon Resource Name (ARN), not the object's ARN. You must update your IAM policies to use the bucket ARN for the encryption context. For more information, see [S3 Bucket Keys and replication](#).

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in [AWS Key Management Service Developer Guide](#).

Using the S3 console

For step-by-step instructions, see [Configuring replication for source and destination buckets owned by the same account](#). This topic provides instructions for setting a replication configuration when the buckets are owned by the same and different AWS accounts.

Using the AWS CLI

To replicate encrypted objects with the AWS CLI, you do the following:

- Create source and destination buckets and enable versioning on these buckets.
- Create an AWS Identity and Access Management (IAM) service role that gives Amazon S3 permission to replicate objects. The IAM role's permissions include the necessary permissions to replicate the encrypted objects.
- Add a replication configuration to the source bucket. The replication configuration provides information related to replicating objects that are encrypted by using KMS keys.
- Add encrypted objects to the source bucket.
- Test the setup to confirm that your encrypted objects are being replicated to the destination bucket.

The following procedures walk you through this process.

To replicate server-side encrypted objects (AWS CLI)

1. In this example, you create both the *DOC-EXAMPLE-SOURCE-BUCKET* and *DOC-EXAMPLE-DESTINATION-BUCKET* buckets in the same AWS account. You also set a credentials profile for the AWS CLI. This example uses the profile name *accta*.

For more information about setting credential profiles, see [Named Profiles in the AWS Command Line Interface User Guide](#). To use the commands in this example, replace the *user input placeholders* with your own information.

2. Use the following commands to create the *DOC-EXAMPLE-SOURCE-BUCKET* bucket and enable versioning on it. The following example commands create the *DOC-EXAMPLE-SOURCE-BUCKET* bucket in the US East (N. Virginia) (us-east-1) Region.

```
aws s3api create-bucket \
--bucket DOC-EXAMPLE-SOURCE-BUCKET \
--region us-east-1 \
--profile accta
```

```
aws s3api put-bucket-versioning \
--bucket DOC-EXAMPLE-SOURCE-BUCKET \
--versioning-configuration Status=Enabled \
```

```
--profile acctA
```

3. Use the following commands to create the *DOC-EXAMPLE-DESTINATION-BUCKET* bucket and enable versioning on it. The following example commands create the *DOC-EXAMPLE-DESTINATION-BUCKET* bucket in the US West (Oregon) (us-west-2) Region.

 **Note**

To set up a replication configuration when both *DOC-EXAMPLE-SOURCE-BUCKET* and *DOC-EXAMPLE-DESTINATION-BUCKET* buckets are in the same AWS account, you use the same profile. In this example, we use *acctA*. To configure replication when the buckets are owned by different AWS accounts, you specify different profiles for each.

```
aws s3api create-bucket \  
--bucket DOC-EXAMPLE-DESTINATION-BUCKET \  
--region us-west-2 \  
--create-bucket-configuration LocationConstraint=us-west-2 \  
--profile acctA
```

```
aws s3api put-bucket-versioning \  
--bucket DOC-EXAMPLE-DESTINATION-BUCKET \  
--versioning-configuration Status=Enabled \  
--profile acctA
```

4. Next, you create an IAM service role. You will specify this role in the replication configuration that you add to the *DOC-EXAMPLE-SOURCE-BUCKET* bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create a service role.
- Attach a permissions policy to the role.

- a. To create an IAM service role, do the following:

- i. Copy the following trust policy and save it to a file called `s3-role-trust-policy-kmsobj.json` in the current directory on your local computer. This policy grants Amazon S3 service principal permissions to assume the role so that Amazon S3 can perform tasks on your behalf.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- ii. Use the following command to create the role:

```
$ aws iam create-role \  
--role-name replicationRolekmsobj \  
--assume-role-policy-document file://s3-role-trust-policy-kmsobj.json \  
--profile accta
```

- b. Next, you attach a permissions policy to the role. This policy grants permissions for various Amazon S3 bucket and object actions.
 - i. Copy the following permissions policy and save it to a file named s3-role-permissions-policykmsobj.json in the current directory on your local computer. You will create an IAM role and attach the policy to it later.

⚠ Important

In the permissions policy, you specify the AWS KMS key IDs that will be used for encryption of the *DOC-EXAMPLE-SOURCE-BUCKET* and *DOC-EXAMPLE-DESTINATION-BUCKET* buckets. You must create two separate KMS keys for the *DOC-EXAMPLE-SOURCE-BUCKET* and *DOC-EXAMPLE-DESTINATION-BUCKET* buckets. AWS KMS keys are not shared outside the AWS Region in which they were created.

```
{  
    "Version": "2012-10-17",
```

```
"Statement": [
    {
        "Action": [
            "s3>ListBucket",
            "s3>GetReplicationConfiguration",
            "s3>GetObjectVersionForReplication",
            "s3>GetObjectVersionAcl",
            "s3>GetObjectVersionTagging"
        ],
        "Effect": "Allow",
        "Resource": [
            "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET",
            "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET/*"
        ]
    },
    {
        "Action": [
            "s3>ReplicateObject",
            "s3>ReplicateDelete",
            "s3>ReplicateTags"
        ],
        "Effect": "Allow",
        "Condition": {
            "StringLikeIfExists": {
                "s3:x-amz-server-side-encryption": [
                    "aws:kms",
                    "AES256",
                    "aws:kms:dsse"
                ],
                "s3:x-amz-server-side-encryption-aws-kms-key-id": [
                    "AWS KMS key IDs(in ARN format) to use for encrypting object replicas"
                ]
            }
        },
        "Resource": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"
    },
    {
        "Action": [
            "kms>Decrypt"
        ],
        "Effect": "Allow",
        "Condition": {
            "StringLike": {

```

```
        "kms:ViaService": "s3.us-east-1.amazonaws.com",
        "kms:EncryptionContext:aws:s3:arn": [
            "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET/*"
        ]
    },
    "Resource": [
        "AWS KMS key IDs(in ARN format) used to encrypt source
        objects."
    ],
},
{
    "Action": [
        "kms:Encrypt"
    ],
    "Effect": "Allow",
    "Condition": {
        "StringLike": {
            "kms:ViaService": "s3.us-west-2.amazonaws.com",
            "kms:EncryptionContext:aws:s3:arn": [
                "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"
            ]
        }
    },
    "Resource": [
        "AWS KMS key IDs(in ARN format) to use for encrypting object
        replicas"
    ],
}
]
```

ii. Create a policy and attach it to the role.

```
$ aws iam put-role-policy \
--role-name replicationRolekmsobj \
--policy-document file://s3-role-permissions-policykmsobj.json \
--policy-name replicationRolechangeownerPolicy \
--profile acctA
```

5. Next, add the following replication configuration to the *DOC-EXAMPLE-SOURCE-BUCKET* bucket. It tells Amazon S3 to replicate objects with the Tax/ prefix to the *DOC-EXAMPLE-DESTINATION-BUCKET* bucket.

⚠ Important

In the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if you have the `iam:PassRole` permission. The profile that you specify in the CLI command must have this permission. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

```
<ReplicationConfiguration>
  <Role>IAM-Role-ARN</Role>
  <Rule>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>Disabled</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <SourceSelectionCriteria>
      <SseKmsEncryptedObjects>
        <Status>Enabled</Status>
      </SseKmsEncryptedObjects>
    </SourceSelectionCriteria>
    <Destination>
      <Bucket>arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET</Bucket>
      <EncryptionConfiguration>
        <ReplicaKmsKeyID>AWS KMS key IDs to use for encrypting object replicas</ReplicaKmsKeyID>
      </EncryptionConfiguration>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

To add a replication configuration to the *DOC-EXAMPLE-SOURCE-BUCKET* bucket, do the following:

- a. The AWS CLI requires you to specify the replication configuration as JSON. Save the following JSON in a file (`replication.json`) in the current directory on your local computer.

```
{  
    "Role": "IAM-Role-ARN",  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Priority": 1,  
            "DeleteMarkerReplication": {  
                "Status": "Disabled"  
            },  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET",  
                "EncryptionConfiguration": {  
                    "ReplicaKmsKeyID": "AWS KMS key IDs (in ARN format) to use for encrypting object replicas"  
                }  
            },  
            "SourceSelectionCriteria": {  
                "SseKmsEncryptedObjects": {  
                    "Status": "Enabled"  
                }  
            }  
        }  
    ]  
}
```

- b. Edit the JSON to provide values for the *DOC-EXAMPLE-DESTINATION-BUCKET* bucket, *AWS KMS key IDs (in ARN format)*, and *IAM-role-ARN*. Save the changes.
- c. Use the following command to add the replication configuration to your *DOC-EXAMPLE-SOURCE-BUCKET* bucket. Be sure to provide the *DOC-EXAMPLE-SOURCE-BUCKET* bucket name.

```
$ aws s3api put-bucket-replication \  
--replication-configuration file://replication.json \  
--bucket DOC-EXAMPLE-SOURCE-BUCKET \  
--profile acctA
```

6. Test the configuration to verify that encrypted objects are replicated. In the Amazon S3 console, do the following:

- a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- b. In the **DOC-EXAMPLE-SOURCE-BUCKET** bucket, create a folder named Tax.
- c. Add sample objects to the folder. Be sure to choose the encryption option and specify your KMS key to encrypt the objects.
- d. Verify that the **DOC-EXAMPLE-DESTINATION-BUCKET** bucket contains the object replicas and that they are encrypted by using the KMS key that you specified in the configuration. For more information, see [the section called "Getting replication status"](#).

Using the AWS SDKs

For a code example that shows how to add a replication configuration, see [Using the AWS SDKs](#). You must modify the replication configuration appropriately.

For conceptual information, see [Replicating objects created with server-side encryption \(SSE-C, SSE-S3, SSE-KMS, DSSE-KMS\)](#).

Replicating objects with S3 Replication Time Control (S3 RTC)

S3 Replication Time Control (S3 RTC) helps you meet compliance or business requirements for data replication and provides visibility into Amazon S3 replication times. S3 RTC replicates most objects that you upload to Amazon S3 in seconds, and 99.99 percent of those objects within 15 minutes.

With S3 RTC, you can monitor the total number and size of objects that are pending replication, and the maximum replication time to the destination Region. Replication metrics are available through the [AWS Management Console](#) and [Amazon CloudWatch User Guide](#). For more information, see [the section called "S3 Replication metrics in CloudWatch "](#).

Using the S3 console

For step-by-step instructions, see [Configuring replication for source and destination buckets owned by the same account](#). This topic provides instructions for enabling S3 RTC in your replication configuration when buckets are owned by same and different AWS accounts.

Using the AWS CLI

To use the AWS CLI to replicate objects with S3 RTC enabled, you create buckets, enable versioning on the buckets, create an IAM role that gives Amazon S3 permission to replicate objects, and add

the replication configuration to the source bucket. The replication configuration needs to have S3 Replication Time Control (S3 RTC) enabled.

To replicate with S3 RTC enabled (AWS CLI)

- The following example sets `ReplicationTime` and `Metric`, and adds replication configuration to the source bucket.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "DeleteMarkerReplication": {  
                "Status": "Disabled"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::destination",  
                "Metrics": {  
                    "Status": "Enabled",  
                    "EventThreshold": {  
                        "Minutes": 15  
                    }  
                },  
                "ReplicationTime": {  
                    "Status": "Enabled",  
                    "Time": {  
                        "Minutes": 15  
                    }  
                }  
            },  
            "Priority": 1  
        }  
    ],  
    "Role": "IAM-Role-ARN"  
}
```

⚠ Important

Metrics:EventThreshold:Minutes and ReplicationTime:Time:Minutes can only have 15 as a valid value.

Using the AWS SDK for Java

The following Java example adds replication configuration with S3 Replication Time Control (S3 RTC).

```
import software.amazon.awssdk.auth.credentials.AwsBasicCredentials;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.model.DeleteMarkerReplication;
import software.amazon.awssdk.services.s3.model.Destination;
import software.amazon.awssdk.services.s3.model.Metrics;
import software.amazon.awssdk.services.s3.model.MetricsStatus;
import software.amazon.awssdk.services.s3.model.PutBucketReplicationRequest;
import software.amazon.awssdk.services.s3.model.ReplicationConfiguration;
import software.amazon.awssdk.services.s3.model.ReplicationRule;
import software.amazon.awssdk.services.s3.model.ReplicationRuleFilter;
import software.amazon.awssdk.services.s3.model.ReplicationTime;
import software.amazon.awssdk.services.s3.model.ReplicationTimeStatus;
import software.amazon.awssdk.services.s3.model.ReplicationTimeValue;

public class Main {

    public static void main(String[] args) {
        S3Client s3 = S3Client.builder()
            .region(Region.US_EAST_1)
            .credentialsProvider(() -> AwsBasicCredentials.create(
                "AWS_ACCESS_KEY_ID",
                "AWS_SECRET_ACCESS_KEY"))
        )
        .build();

        ReplicationConfiguration replicationConfig = ReplicationConfiguration
            .builder()
            .rules(
                ReplicationRule
                    .builder()
                    .status("Enabled")
            )
    }
}
```

```
.priority(1)
.deleteMarkerReplication(
    DeleteMarkerReplication
        .builder()
        .status("Disabled")
        .build()
)
.destination(
    Destination
        .builder()
        .bucket("destination_bucket_arn")
        .replicationTime(
            ReplicationTime.builder().time(
                ReplicationTimeValue.builder().minutes(15).build()
            ).status(
                ReplicationTimeStatus.ENABLED
            ).build()
        )
        .metrics(
            Metrics.builder().eventThreshold(
                ReplicationTimeValue.builder().minutes(15).build()
            ).status(
                MetricsStatus.ENABLED
            ).build()
        )
        .build()
)
.filter(
    ReplicationRuleFilter
        .builder()
        .prefix("testtest")
        .build()
)
.build())
.role("role_arn")
.build();

// Put replication configuration
PutBucketReplicationRequest putBucketReplicationRequest =
PutBucketReplicationRequest
    .builder()
    .bucket("source_bucket")
    .replicationConfiguration(replicationConfig)
    .build();
```

```
s3.putBucketReplication(putBucketReplicationRequest);  
}  
}
```

For more information, see [Meeting compliance requirements using S3 Replication Time Control \(S3 RTC\)](#).

Managing replication rules using the Amazon S3 console

Replication is the automatic, asynchronous copying of objects across buckets in the same or different AWS Regions. It replicates newly created objects and object updates from a source bucket to a specified destination bucket.

You use the Amazon S3 console to add replication rules to the source bucket. Replication rules define the source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. For more information about replication, see [Replicating objects](#).

You can manage replication rules on the **Replication** page. You can add, view, enable, disable, delete, and change the priority of the replication rules. For information about adding replication rules to a bucket, see [Using the S3 console](#).

To manage the replication rules for an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. Choose **Management**, and then scroll down to **Replication rules**.
4. You change the replication rules in the following ways.
 - To enable or disable a replication rule, select the rule, choose **Actions**, and in the drop-down list, choose **Enable rule** or **Disable rule**. You can also disable, enable, or delete all the rules in the bucket from the **Actions** drop-down list.
 - To change the rule priorities, select the rule and choose **Edit**, which starts the Replication wizard to help you make the change. For information about using the wizard, see [Using the S3 console](#).

You set rule priorities to avoid conflicts caused by objects that are included in the scope of more than one rule. In the case of overlapping rules, Amazon S3 uses the rule priority to

determine which rule to apply. The higher the number, the higher the priority. For more information about rule priority, see [Replication configuration](#).

Replicating existing objects with S3 Batch Replication

S3 Batch Replication provides you a way to replicate objects that existed before a replication configuration was in place, objects that have previously been replicated, and objects that have failed replication. This is done through the use of a Batch Operations job. This differs from live replication which continuously and automatically replicates new objects across Amazon S3 buckets. To get started with Batch Replication you may:

- **Initiate Batch Replication for a new replication rule or destination** – You may create a one-time Batch Replication job when creating the first rule in a new replication configuration or when adding a new destination to an existing configuration through the AWS Management Console.
- **Initiate Batch Replication for an existing replication configuration** – You can create a new Batch Replication job using **S3 Batch Operations** through the AWS SDKs, AWS Command Line Interface (AWS CLI), or the Amazon S3 console.

When the Batch Replication job finishes, you receive a completion report. For more information about how to use the report to examine the job, see [Tracking job status and completion reports](#).

S3 Batch Replication considerations

- Your source bucket must have an existing replication configuration. To enable replication, see [Setting up replication](#) and [Walkthroughs: Examples for configuring replication](#).
- If you have S3 Lifecycle configured for your bucket, we recommend disabling your Lifecycle rules while the Batch Replication job is active. This will ensure parity between the source and destination buckets. Otherwise these buckets could diverge and the destination bucket will not be an exact replica of the source bucket. Consider the following:
 - Your source bucket has multiple versions on an object and a delete marker.
 - Your source and destination buckets have a lifecycle configuration to remove expired delete markers.

Batch Replication may replicate the delete marker to the destination bucket before replicating the object versions. This could result in the delete marker being marked as expired and being removed from the destination bucket before the objects are copied.

- The AWS Identity and Access Management (IAM) role that you specify to run the Batch Operations job must have permissions to perform the underlying Batch Replication operation. For more information about creating IAM roles, see [Configuring IAM policies for Batch Replication](#).
- Batch Replication requires a manifest which can be generated by Amazon S3. The generated manifest must be stored in the same AWS Region as the source bucket. If you choose to not generate the manifest you may supply an Amazon S3 Inventory report or CSV file that contains the objects you wish to replicate.
- Batch Replication does not support re-replicating objects that were deleted with the version ID of the object from the destination bucket. To re-replicate these objects you can copy the source objects in place with a Batch Copy job. Copying those objects in place will create new versions of the object in the source bucket and initiate replication automatically to the destination. Deleting and recreating the destination bucket will not initiate replication.

For more information on Batch Copy, see, [Examples that use Batch Operations to copy objects](#).

- If you're using a replication rule on the S3 bucket, make sure to [update your replication configuration](#), granting the IAM role attached to the replication rule, proper permissions to replicate objects. The IAM role must have permissions to perform the S3 action on both the source and destination bucket.
- If you submit multiple Batch Replication jobs for the same bucket within a short time frame, S3 will run those jobs concurrently.
- If you submit multiple Batch Replication jobs for two different buckets, be aware that S3 might not run all jobs concurrently. If you exceed the number of Batch Replication jobs that can run at one time on your account, S3 will pause the lower priority jobs to work on the higher priority ones. After the higher priority items have completed, any paused jobs will become active again.
- Batch replication is not supported for objects stored in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.
- To batch replicate S3 Intelligent-Tiering objects stored in the Archive Access or Deep Archive Access storage tier, you must first initiate a [restore](#) request and wait until the objects are moved to the Frequent Access tier.

Specifying a manifest for a Batch Replication job

A manifest is an Amazon S3 object that contains object keys that you want Amazon S3 to act upon. If you wish to create a Batch Replication job you must supply either a user-generated manifest or have Amazon S3 generate a manifest based on your replication configuration.

If you supply a user-generated manifest it must be in the form of a Amazon S3 Inventory report or CSV file. If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. Only the object with the version ID specified in the manifest will be replicated. To learn more about specifying a manifest, see [Specifying a manifest](#).

If you choose to have Amazon S3 generate a manifest file on your behalf the objects listed will use the same source bucket, prefix, and tags as all your replication configurations of the source bucket. With a generated manifest Amazon S3 will replicate all eligible versions of your objects.

 **Note**

If you choose to have the manifest generated it must be stored in the same AWS Region as the source bucket.

Filters for a Batch Replication job

When creating your Batch Replication job you can optionally specify additional filters, such as object creation date and replication status to reduce the scope of the job.

You can filter objects to replicate based on the ObjectReplicationStatuses value, by providing one or more of the following values:

- "NONE" – Indicates that Amazon S3 has never attempted to replicate the object before.
- "FAILED" – Indicates that Amazon S3 has attempted, but failed to replicate the object before.
- "COMPLETED" – Indicates that Amazon S3 has successfully replicated the object before.
- "REPLICA" – Indicates that this is a replica object that Amazon S3 replicated from another source.

For more information about replication statuses, see [Getting replication status information](#).

If you do not filter based on replication status Batch Operations will attempt to replicate everything eligible. Depending on your goal, you might set `ObjectReplicationStatuses` to one of the following values:

- If you want to replicate only existing objects that have never been replicated, only include "NONE".
- If you want to retry replicating only objects that previously failed to replicate, only include "FAILED".
- If you want to both replicate existing objects and retry replicating objects that previously failed to replicate, include both "NONE" and "FAILED".
- If you want to back-fill a destination bucket with objects that have been replicated to another destination, include "COMPLETED".
- If you want replicate objects previously replicated, include "REPLICA".

Batch Replication completion report

When you create a Batch Replication job, you can request a CSV completion report. This report shows objects, replication success or failure codes, outputs, and descriptions. For more information about job tracking and completion reports see, [Completion reports](#).

For a list of Replication failure codes and descriptions see, [Amazon S3 replication failure reasons](#).

Getting started with Batch Replication

To learn more about how to use Batch Replication, see [Tutorial: Replicating existing objects in your Amazon S3 buckets with S3 Batch Replication](#).

Configuring IAM policies for Batch Replication

Because S3 Batch Replication is a type of Batch Operations job, you must create a Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf. You also must attach a Batch Replication IAM policy to the Batch Operations IAM role. The following example creates an IAM role that gives Batch Operations permission to initiate a Batch Replication job.

Create IAM role and policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Under **Access management**, choose **Roles**.
3. Choose **Create Role**.
4. Choose **AWS service** as the type of trusted entity, **Amazon S3** as the service, and **S3 Batch Operations** as the use case.
5. Choose **Next: Permissions**.
6. Choose **Create Policy**.
7. Choose **JSON** and insert one of the following policies based on your manifest.

 **Note**

Different permission are needed if you are generating a manifest or supplying one. For more information see, [Specifying a manifest for a Batch Replication job](#).

Policy if using and storing a S3 generated manifest

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "s3:InitiateReplication"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::*** replication source bucket ***/*"  
            ]  
        },  
        {  
            "Action": [  
                "s3:GetReplicationConfiguration",  
                "s3:PutInventoryConfiguration"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::*** replication source bucket ***"  
            ]  
        }  
    ]  
}
```

```
},
{
  "Action":[
    "s3:GetObject",
    "s3:GetObjectVersion"
  ],
  "Effect":"Allow",
  "Resource":[
    "arn:aws:s3:::*** manifest bucket ***/*"
  ]
},
{
  "Effect":"Allow",
  "Action":[
    "s3:PutObject"
  ],
  "Resource":[
    "arn:aws:s3:::*** completion report bucket ****/*",
    "arn:aws:s3:::*** manifest bucket ****/*"
  ]
}
]
}
```

Policy if using a user supplied manifest

```
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Action":[
        "s3:InitiateReplication"
      ],
      "Effect":"Allow",
      "Resource":[
        "arn:aws:s3:::*** replication source bucket ***/*"
      ]
    },
    {
      "Action":[
        "s3:GetObject",
        "s3:GetObjectVersion"
      ],
      "Effect":"Allow",
      "Resource":[
        "arn:aws:s3:::*** replication destination bucket ***/*"
      ]
    }
  ]
}
```

```
        "Effect":"Allow",
        "Resource":[
            "arn:aws:s3:::*** manifest bucket ***/*"
        ],
    },
{
    "Effect":"Allow",
    "Action":[
        "s3:PutObject"
    ],
    "Resource":[
        "arn:aws:s3:::*** completion report bucket ****/*"
    ]
}
]
```

8. Choose **Next: Tags**.
9. Choose **Next: Review**.
10. Choose a name for the policy and choose **Create policy**.
11. Attach this policy to your role and choose **Next: Tags**.
12. Choose **Next: Review**.
13. Choose a name for the role and choose **Create role**.

Verify trust policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Under **Access management**, choose **Roles**, and select your newly created role.
3. Under **Trust relationships** tab, choose **Edit trust relationship**.
4. Verify this role is using the following trust policy:

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Principal":{
```

```
        "Service": "batchoperations.s3.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
}
]
```

Create a Batch Replication job for a first replication rule or new destination

When you create the first rule in a new replication configuration or add a new destination to an existing configuration through the AWS Management Console, you can optionally create a Batch Replication job.

To use Batch Replication for an existing configuration without adding a new destination see, [Create a Batch Replication job for existing replication rules](#).

Using Batch Replication for a new replication rule or destination through the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to replicate.
3. To create a new replication rule or edit an existing rule, choose **Management**, and scroll down to **Replication rules**:
 - To create a new replication rule, choose **Create replication rule**.

 **Note**

For examples on how to set up a basic replication rule see, [Walkthroughs: Examples for configuring replication](#).

- To edit an existing replication rule, select the rule, and then choose **Edit rule**.
4. Create your new replication rule or edit the destination for your existing replication rule, and choose **Save**.

After you create the first rule in a new replication configuration or edit an existing configuration to add a new destination, a **Replicate existing objects?** dialog appears, giving you the option to create a Batch Replication job.

5. If you want to run this job now, choose **Yes, replicate existing objects**.

If you want to run this job at a later time, choose **No, do not replicate existing objects**.

6. Create your S3 Batch Replication job. The S3 Batch Replication job has several settings:

Job run option

If you want the S3 Batch Replication job to run immediately, you can choose **Job runs automatically when ready**. If you want to run the job at a later time, choose **Job waits to be run when ready**.

If you choose **Job runs automatically when ready**, you will not be able to create and save a Batch Operations manifest. To save the Batch Operations manifest, choose **Job waits to be run when ready**.

Batch Operations manifest

The manifest is a list of all of the objects that you want to run the specified action on. You can choose to save the Batch Operations manifest. Similar to S3 Inventory files, the manifest will be saved as a CSV file and stored in a bucket. To learn more about Batch Operations manifests, see [Specifying a manifest](#).

Completion report

S3 Batch Operations execute one task for each object specified in the manifest. Completion reports provide an easy way to view the results of your tasks in a consolidated format with no additional setup required. You can request a completion report for all tasks or only for failed tasks. To learn more about completion reports, see [Completion reports](#).

Permissions

One of the most common causes of replication failures is insufficient permissions in the provided AWS Identity and Access Management (IAM) role. For information about creating this role see, [Configuring IAM policies for Batch Replication](#).

7. Choose **Create Batch Operations job**.

Create a Batch Replication job for existing replication rules

You can configure S3 Batch Replication for an existing replication configuration by using the AWS SDKs, AWS Command Line Interface (AWS CLI), or the Amazon S3 console. For an overview of Batch Replication see, [Replicating existing objects with S3 Batch Replication](#).

As a prerequisite, you must create a Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf, see [Configuring IAM policies for Batch Replication](#).

When the Batch Replication job finishes, you receive a completion report. For more information about how to use the report to examine the job, see [Tracking job status and completion reports](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose **Batch Operations** on the navigation pane of the Amazon S3 console.
3. Choose **Create job**.
4. Choose the **Region** where you want to create your job.
5. Select the **Manifest format**. This example will show how to create a manifest based on an existing S3 replication configuration.

 **Note**

The manifest is a list of all of the objects that you want to run the specified action on. To learn more about Batch Operations manifests, see [Specifying a manifest](#). If you have a manifest prepared, choose **S3 inventory report (manifest.json)** or **CSV**. If the objects in your manifest are in a versioned bucket, you should specify the version IDs for the objects. For more information about creating a manifest see, [Specifying a manifest](#).

6. To create a manifest based on your replication configuration, choose **Create manifest using S3 Replication configuration**. Then chose the source bucket of your replication configuration.
7. (Optional) You may include additional filters such as object creation date and replication status. For examples on how to filter by replication status see, [Specifying a manifest for a Batch Replication job](#).

8. To save a manifest, select **Save Batch Operations manifest**.
 - a. If you choose to generate and save a manifest, you must choose either **Bucket in this account** or **Bucket in another AWS account**. Specify the bucket name in the text box.

 **Note**
The generated manifest must be stored in the same AWS Region as the source bucket.

- b. Choose the **Encryption type**.
9. (Optional) Provide a **Description**.
10. Adjust the **Priority** of the job if needed. Higher numbers indicate higher priority. Amazon S3 attempts to run higher priority jobs before lower priority jobs. For more information about job priority, see [Assigning job priority](#).
11. (Optional) Generate a completion report. To generate select **Generate completion report**.
If you choose to generate a completion report, you must choose either to report **Failed tasks only** or **All tasks**, and provide a destination bucket for the report.
12. Select a valid IAM role.

 **Note**
For more information about creating a IAM role, see [Configuring IAM policies for Batch Replication](#).
13. (Optional) Add job tags to the Batch Replication job.
14. Choose **Next**.
15. Review your job configuration and select **Create job**.

Using the AWS CLI with an S3 manifest

The following example creates an S3 Batch Replication job using a S3 generated manifest for the AWS account **111122223333**. This example will try to replicate existing objects and objects that previously failed to replicate. For information about filtering by replication status see, [Specifying a manifest for a Batch Replication job](#).

```
aws s3control create-job --account-id 111122223333 --operation  
'{"S3ReplicateObject":{}}' --report '{"Bucket":"arn:aws:s3:::***  
completion report bucket ****", "Prefix":"batch-replication-report",  
"Format":"Report_CSV_20180820","Enabled":true,"ReportScope":"AllTasks"}'  
--manifest-generator '{"S3JobManifestGenerator": {"ExpectedBucketOwner":  
"111122223333", "SourceBucket": "arn:aws:s3:::*** replication source bucket  
***", "EnableManifestOutput": false, "Filter": {"EligibleForReplication": true,  
"ObjectReplicationStatuses": ["NONE","FAILED"]}}}' --priority 1 --role-arn  
arn:aws:iam::111122223333:role/batch-Replication-IAM-policy --no-confirmation-required  
--region source-bucket-region
```

Note

The job must be initiated from the same AWS Region replication source bucket. The IAM role **role/batch-Replication-IAM-policy** was previously created. See [Configuring IAM policies for Batch Replication](#).

After you have successfully initiated a Batch Replication job, you receive the job ID as the response. You can monitor this job using the following command.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id --region source-bucket-region
```

Using the AWS CLI with a user-provided manifest

The following example creates an S3 Batch Replication job using a user-defined manifest for AWS account **111122223333**. If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. Only the object with the version ID specified in the manifest will be replicated. For more information about creating a manifest see, [Specifying a manifest](#).

```
aws s3control create-job --account-id 111122223333 --operation  
'{"S3ReplicateObject":{}}' --report '{"Bucket":"arn:aws:s3:::***  
completion report bucket ****", "Prefix":"batch-replication-report",  
"Format":"Report_CSV_20180820","Enabled":true,"ReportScope":"AllTasks"}'  
--manifest '{"Spec":{"Format":"S3BatchOperations_CSV_20180820","Fields":  
["Bucket","Key","VersionId"],"Location":{"ObjectArn":"arn:aws:s3:::*** completion  
report bucket ****/manifest.csv","ETag":"Manifest Etag"}}}' --priority 1 --role-arn  
arn:aws:iam::111122223333:role/batch-Replication-IAM-policy --no-confirmation-required  
--region source-bucket-region
```

Note

The job must be initiated from the same AWS Region replication source bucket. The IAM role `role/batch-Replication-IAM-policy` was previously created. See [Configuring IAM policies for Batch Replication](#).

After you have successfully initiated a Batch Replication job, you receive the job ID as the response. You can monitor this job using the following command.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id --region source-bucket-region
```

Additional replication configurations

This section describes additional replication configuration options that are available in Amazon S3. For information about core replication configuration, see [Setting up replication](#).

Topics

- [Monitoring progress with replication metrics and S3 Event Notifications](#)
- [Meeting compliance requirements using S3 Replication Time Control \(S3 RTC\)](#)

Monitoring progress with replication metrics and S3 Event Notifications

S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

S3 Replication metrics are turned on automatically when you enable S3 Replication Time Control (S3 RTC). You can also enable S3 Replication metrics independently of S3 RTC while creating or editing a rule. S3 RTC includes other features, such as a service level agreement (SLA) and notifications for missed thresholds. For more information, see [Meeting compliance requirements using S3 Replication Time Control \(S3 RTC\)](#).

The bytes pending, operations pending, and replication-latency metrics apply only to new objects that are replicated with S3 Cross-Region Replication (S3 CRR) or S3 Same-Region Replication (S3 SRR). The operations failing replication metric tracks both new objects that are replicated with S3 CRR or S3 SRR and existing objects that are replicated with S3 Batch Replication. To assist in troubleshooting any configuration issues, you can also set up Amazon S3 Event Notifications to receive replication-failure events.

When enabled, S3 Replication metrics publish the following metrics to Amazon CloudWatch:

- **Bytes Pending Replication** – The total number of bytes of objects that are pending replication for a given replication rule.
- **Replication Latency** – The maximum number of seconds by which the replication destination buckets are behind the source bucket for a given replication rule.
- **Operations Pending Replication** – The number of operations that are pending replication for a given replication rule. This metric tracks operations related to objects, delete markers, tags, access control lists (ACLs), and S3 Object Lock.
- **Operations Failed Replication** – The number of operations that failed replication for a given replication rule. This metric tracks operations related to objects, delete markers, tags, ACLs, and Object Lock. Unlike the other replication metrics, this metric applies both to new objects that are replicated with S3 CRR or S3 SRR and to existing objects that are replicated with S3 Batch Replication.

 **Note**

Operations Failed Replication tracks S3 Replication failures aggregated at a per-minute interval. To identify the specific objects that have failed replication and their failure reasons, subscribe to the `OperationFailedReplication` event in Amazon S3 Event Notifications. For more information, see [Receiving replication failure events with Amazon S3 Event Notifications](#).

If a job fails to run at all, metrics are not sent to Amazon CloudWatch. For example, your job won't run if you don't have the necessary permissions to run an S3 Batch Replication job, or if the tags or prefix in your replication configuration don't match.

Enabling S3 Replication metrics

You can start using S3 Replication metrics with a new or existing replication rule. You can choose to apply your replication rule to an entire S3 bucket, or to Amazon S3 objects with a specific prefix or tag.

This topic provides instructions for enabling S3 Replication metrics in your replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable replication metrics by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the source bucket with Metrics enabled. In this example configuration, objects under the prefix *Tax* are replicated to the destination bucket *DOC-EXAMPLE-BUCKET*, and metrics are generated for those objects.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::DOC-EXAMPLE-BUCKET",  
                "Metrics": {  
                    "Status": "Enabled"  
                }  
            },  
            "Priority": 1  
        }  
    "Role": "IAM-Role-ARN"  
}
```

For full instructions on creating replication rules, see [Configuring replication for source and destination buckets owned by the same account](#).

For more information about viewing replication metrics in the S3 console, see [Viewing replication metrics by using the Amazon S3 console](#).

 **Note**

S3 Replication metrics are billed at the same rate as Amazon CloudWatch custom metrics.

For more information, see [Amazon CloudWatch pricing](#).

Receiving replication failure events with Amazon S3 Event Notifications

S3 Event Notifications can notify you in instances when objects don't replicate to their destination AWS Region. Amazon S3 events are available through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [the section called "Amazon S3 Event Notifications"](#).

For a list of failure codes captured by S3 Event Notifications, see [Amazon S3 replication failure reasons](#).

Viewing replication metrics by using the Amazon S3 console

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. S3 Replication metrics are turned on automatically when you enable replication with S3 Replication Time Control (S3 RTC) by using the AWS Management Console or the Amazon S3 API. You can also enable S3 Replication metrics independently of S3 RTC while creating or editing a rule.

Replication metrics track the rule IDs of the replication configuration. A replication rule ID can be specific to a prefix, a tag, or a combination of both.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

Prerequisites

Enable a replication rule that has S3 Replication metrics.

To view replication metrics

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Buckets**. In the **Buckets** list, choose the name of the bucket that contains the objects that you want replication metrics for.
3. Choose the **Metrics** tab.
4. Under **Replication metrics**, choose **Replication rules**.
5. Choose **Display charts**.

Amazon S3 displays **Replication latency (in seconds)**, **Bytes pending replication**, **Operations pending replication**, and **Operations failed replication** charts.

You can then view the replication metrics **Replication latency (in seconds)**, **Operations pending replication**, **Bytes pending replication**, and **Operations failed replication** for the rules that you selected. If you're using S3 Replication Time Control, Amazon CloudWatch begins reporting replication metrics 15 minutes after you enable S3 RTC on the respective replication rule. You can view replication metrics on the Amazon S3 console or the CloudWatch console. For more information, see [Replication metrics with S3 RTC](#).

Amazon S3 replication failure reasons

The following table lists Amazon S3 Replication failure reasons. You can view these reasons by receiving the **failureReason** event with Amazon S3 Event Notifications. You can receive S3 Event Notifications through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [Amazon S3 Event Notifications](#).

You can also view these failure reasons in an S3 Batch Replication completion report. For more information, see [Batch Replication completion report](#).

Replication failure reason	Description
AssumeRoleNotPermitted	Amazon S3 can't assume the AWS Identity and Access Management (IAM) role that's specified in the replication configuration or in the Batch Operations job.
DstBucketInvalidRegion	The destination bucket is not in the same AWS Region as specified by the Batch Operations job. This error is specific to Batch Replication.

Replication failure reason	Description
DstBucketNotFound	Amazon S3 is unable to find the destination bucket that's specified in the replication configuration.
DstBucketObjectLockConfigMissing	To replicate objects from a source bucket with Object Lock enabled, the destination bucket must also have Object Lock enabled. This error indicates that Object Lock might not be enabled in the destination bucket. For more information, see Object Lock considerations .
DstBucketUnversioned	Versioning is not enabled for the S3 destination bucket. To replicate objects with S3 Replication, enable versioning for the destination bucket.
DstDelObjNotPermitted	Amazon S3 is unable to replicate delete markers to the destination bucket. The s3:ReplicateDelete permission might be missing for the destination bucket.
DstKmsKeyInvalidState	The AWS Key Management Service (AWS KMS) key for the destination bucket isn't in a valid state. Review and enable the required AWS KMS key. For more information about managing AWS KMS keys, see Key states of AWS KMS keys in the <i>AWS Key Management Service Developer Guide</i> .
DstKmsKeyNotFound	The AWS KMS key that's configured for the destination bucket in the replication configuration doesn't exist.

Replication failure reason	Description
DstMultipartCompleteNotPermitted	Amazon S3 is unable to complete multipart uploads of objects in the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstMultipartInitNotPermitted	Amazon S3 is unable to initiate multipart uploads of objects to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstMultipartPartUploadNotPermitted	Amazon S3 is unable to upload multipart objects to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstObjectHardDeleted	S3 Batch Replication does not support re-replicating objects deleted with the version ID of the object from the destination bucket. This error is specific to Batch Replication.
DstPutAclNotPermitted	Amazon S3 is unable to replicate object access control lists (ACLs) to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstPutLegalHoldNotPermitted	Amazon S3 is unable to put an Object Lock legal hold on the destination objects when it is replicating immutable objects. The <code>s3:PutObjectLegalHold</code> permission might be missing for the destination bucket. For more information, see Legal holds .

Replication failure reason	Description
DstPutObjectNotPermitted	Amazon S3 is unable to replicate objects to the destination bucket. The <code>s3:ReplicateObject</code> or <code>s3:ObjectOwnerOverrideToBucketOwner</code> permissions might be missing for the destination bucket.
DstPutTaggingNotPermitted	Amazon S3 is unable to replicate object tags to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstVersionNotFound	Amazon S3 is unable to find the required object version in the destination bucket for which metadata needs to be replicated.
InitiateReplicationNotPermitted	Amazon S3 is unable to initiate replication on objects. The <code>s3:InitiateReplication</code> permission might be missing for the Batch Operations job. This error is specific to Batch Replication.
SrcBucketInvalidRegion	The source bucket is not in the same AWS Region as specified by the Batch Operations job. This error is specific to Batch Replication.
SrcBucketNotFound	Amazon S3 is unable to find the source bucket.
SrcBucketReplicationConfigMissing	Amazon S3 couldn't find a replication configuration for the source bucket.

Replication failure reason	Description
SrcGetAclNotPermitted	<p>Amazon S3 is unable to access the object in the source bucket for replication. The <code>s3:GetObjectVersionAcl</code> permission might be missing for the source bucket object.</p> <p>The objects in the source bucket must be owned by the bucket owner. If ACLs are enabled, then verify if Object Ownership is set to Bucket owner preferred or Object writer. If Object Ownership is set to Bucket owner preferred, then the source bucket objects must have the <code>bucket-owner-full-control</code> ACL for the bucket owner to become the object owner. The source account can take ownership of all objects in their bucket by setting Object Ownership to Bucket owner enforced and disabling ACLs.</p>
SrcGetLegalHoldNotPermitted	Amazon S3 is unable to access the S3 Object Lock legal hold information.
SrcGetObjectNotPermitted	Amazon S3 is unable to access the object in the source bucket for replication. The <code>s3:GetObjectVersionForReplication</code> permission might be missing for the source bucket.
SrcGetRetentionNotPermitted	Amazon S3 is unable to access the S3 Object Lock retention period information.
SrcGetTaggingNotPermitted	Amazon S3 is unable to access object tag information from the source bucket. The <code>s3:GetObjectVersionTagging</code> permission might be missing for the source bucket.

Replication failure reason	Description
SrcHeadObjectNotPermitted	Amazon S3 is unable to retrieve object metadata from the source bucket. The <code>s3:GetObjectVersionForReplication</code> permission might be missing for the source bucket.
SrcKeyNotFound	Amazon S3 is unable to find the source object key to replicate. Source object may have been deleted before replication was complete.
SrcKmsKeyInvalidState	The AWS KMS key for the source bucket isn't in a valid state. Review and enable the required AWS KMS key. For more information about managing AWS KMS keys, see Key states of AWS KMS keys in the <i>AWS Key Management Service Developer Guide</i> .
SrcObjectNotEligible	Some objects aren't eligible for replication. This may be due to the object's storage class or the object tags don't match the replication configuration.
SrcObjectNotFound	Source object does not exist.
SrcReplicationNotPending	Amazon S3 has already replicated this object. This object is no longer pending replication.
SrcVersionNotFound	Amazon S3 is unable to find the source object version to replicate. Source object version may have been deleted before replication was complete.

[Troubleshooting replication](#)

Meeting compliance requirements using S3 Replication Time Control (S3 RTC)

S3 Replication Time Control (S3 RTC) helps you meet compliance or business requirements for data replication and provides visibility into Amazon S3 replication times. S3 RTC replicates most objects that you upload to Amazon S3 in seconds, and 99.99 percent of those objects within 15 minutes.

S3 RTC by default includes S3 Replication metrics and S3 event notifications, with which you can monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, and the maximum replication time. Replication metrics can be enabled independently of S3 RTC, see [Monitoring progress with replication metrics](#). Additionally, S3 RTC provides OperationMissedThreshold and OperationReplicatedAfterThreshold events that notify the bucket owner if object replication exceeds or replicates after the 15-minute threshold.

With S3 RTC, Amazon S3 events can notify you in the rare instance when objects do not replicate within 15 minutes and when those objects replicate after the 15 minute threshold. Amazon S3 events are available through Amazon SQS, Amazon SNS, or AWS Lambda. For more information, see [the section called “Amazon S3 Event Notifications”](#).

Topics

- [Replication metrics with S3 RTC](#)
- [Using Amazon S3 event notifications to track replication objects](#)
- [Best practices and guidelines for S3 RTC](#)

Enabling S3 Replication Time Control

You can start using S3 Replication Time Control (S3 RTC) with a new or existing replication rule. You can choose to apply your replication rule to an entire S3 bucket, or to Amazon S3 objects with a specific prefix or tag. When you enable S3 RTC, replication metrics are also enabled on your replication rule.

If you are using the latest version of the replication configuration (that is, you specify the `Filter` element in a replication configuration rule), Amazon S3 does not replicate the delete marker by default. However you can add delete marker replication to non-tag-based rules.

 **Note**

Replication metrics are billed at the same rate as Amazon CloudWatch custom metrics. For information, see [Amazon CloudWatch pricing](#).

For more information about creating a rule with S3 RTC, see [Replicating objects with S3 Replication Time Control \(S3 RTC\)](#).

Replication metrics with S3 RTC

Replication rules with S3 Replication Time Control (S3 RTC) enabled publishes replication metrics. With replication metrics, you can monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination Region, and the total number of operations that failed replication. You can then monitor each dataset that you replicate separately.

Replication metrics are available within 15 minutes of enabling S3 RTC. Replication metrics are available through the [Amazon S3 console](#), the [Amazon S3 API](#), the AWS SDKs, the [AWS Command Line Interface \(AWS CLI\)](#), and [Amazon CloudWatch](#). For more information, see [Monitoring metrics with Amazon CloudWatch](#).

For more information about finding replication metrics via the Amazon S3 console, see [Viewing replication metrics by using the Amazon S3 console](#).

Using Amazon S3 event notifications to track replication objects

You can track replication time for objects that did not replicate within 15 minutes by monitoring specific event notifications that S3 Replication Time Control (S3 RTC) publishes. These events are published when an object that was eligible for replication using S3 RTC didn't replicate within 15 minutes, and when that object replicates after the 15 minute threshold.

Replication events are available within 15 minutes of enabling S3 RTC. Amazon S3 events are available through Amazon SQS, Amazon SNS, or AWS Lambda. For more information, see [Amazon S3 Event Notifications](#).

Best practices and guidelines for S3 RTC

When replicating data in Amazon S3 using S3 Replication Time Control (S3 RTC), follow these best practice guidelines to optimize replication performance for your workloads.

Topics

- [Amazon S3 Replication and request rate performance guidelines](#)
- [Estimating your replication request rates](#)
- [Exceeding S3 RTC data transfer rate limits](#)
- [AWS KMS encrypted object replication request rates](#)

Amazon S3 Replication and request rate performance guidelines

When uploading and retrieving storage from Amazon S3, your applications can achieve thousands of transactions per second in request performance. For example, an application can achieve at least 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per prefix in an S3 bucket, including the requests that S3 replication makes on your behalf. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by parallelizing reads. For example, if you create 10 prefixes in an S3 bucket to parallelize reads, you could scale your read performance to 55,000 read requests per second.

Amazon S3 automatically scales in response to sustained request rates above these guidelines, or sustained request rates concurrent with LIST requests. While Amazon S3 is internally optimizing for the new request rate, you might receive HTTP 503 request responses temporarily until the optimization is complete. This might occur with increases in request per second rates, or when you first enable S3 RTC. During these periods, your replication latency might increase. The S3 RTC service level agreement (SLA) doesn't apply to time periods when Amazon S3 performance guidelines on requests per second are exceeded.

The S3 RTC SLA also doesn't apply during time periods where your replication data transfer rate exceeds the default 1 Gbps limit. If you expect your replication transfer rate to exceed 1 Gbps, you can contact [AWS Support Center](#) or use [Service Quotas](#) to request an increase in your limit.

Estimating your replication request rates

Your total request rate including the requests that Amazon S3 replication makes on your behalf should be within the Amazon S3 request rate guidelines for both the replication source and

destination buckets. For each object replicated, Amazon S3 replication makes up to five GET/HEAD requests and one PUT request to the source bucket, and one PUT request to each destination bucket.

For example, if you expect to replicate 100 objects per second, Amazon S3 replication might perform an additional 100 PUT requests on your behalf for a total of 200 PUTs per second to the source S3 bucket. Amazon S3 replication also might perform up to 500 GET/HEAD (5 GET/HEAD requests for each object replicated.)

 **Note**

You incur costs for only one PUT request per object replicated. For more information, see the pricing information in the [Amazon S3 FAQ on replication](#).

Exceeding S3 RTC data transfer rate limits

If you expect your S3 Replication Time Control data transfer rate to exceed the default 1 Gbps limit, contact [AWS Support Center](#) or use [Service Quotas](#) to request an increase in your limit.

AWS KMS encrypted object replication request rates

When you replicate objects encrypted with server-side encryption (SSE-KMS) using Amazon S3 replication, AWS Key Management Service (AWS KMS) requests per second limits apply. AWS KMS might reject an otherwise valid request because your request rate exceeds the limit for the number of requests per second. When a request is throttled, AWS KMS returns a `ThrottlingException` error. The AWS KMS request rate limit applies to requests you make directly and to requests made by Amazon S3 replication on your behalf.

For example, if you expect to replicate 1,000 objects per second, you can subtract 2,000 requests from your AWS KMS request rate limit. The resulting request rate per second is available for your AWS KMS workloads excluding replication. You can use [AWS KMS request metrics in Amazon CloudWatch](#) to monitor the total AWS KMS request rate on your AWS account.

Replicating delete markers between buckets

By default, when S3 Replication is enabled and an object is deleted in the source bucket, Amazon S3 adds a delete marker in the source bucket only. This action protects data from malicious deletions.

If you have *delete marker replication* enabled, these markers are copied to the destination buckets, and Amazon S3 behaves as if the object was deleted in both source and destination buckets. For more information about how delete markers work, see [Working with delete markers](#).

Note

Delete marker replication is not supported for tag-based replication rules. Delete marker replication also does not adhere to the 15-minute SLA granted when using S3 Replication Time Control.

If you are not using the latest replication configuration version, delete operations will affect replication differently. For more information, see [How delete operations affect replication](#).

Enabling delete marker replication

You can start using delete marker replication with a new or existing replication rule. You can apply it to an entire S3 bucket or to Amazon S3 objects that have a specific prefix.

To enable delete marker replication using the Amazon S3 console, see [Using the S3 console](#). This topic provides instructions for enabling delete marker replication in your replication configuration when buckets are owned by the same or different AWS accounts.

To enable delete marker replication using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the source bucket with `DeleteMarkerReplication` enabled.

In the following example configuration, delete markers are replicated to the destination bucket `DOC-EXAMPLE-BUCKET` for objects under the prefix `Tax`.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "DeleteMarkerReplication": {  
                "Status": "Enabled"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::DOC-EXAMPLE-BUCKET"  
            }  
        }  
    ]  
}
```

```
        },
        "Priority": 1
    }
],
"Role": "IAM-Role-ARN"
}
```

For full instructions on creating replication rules through the AWS CLI, see [Configuring replication for source and destination buckets owned by the same account](#) in the Replication walkthroughs section.

Replicating metadata changes with Amazon S3 replica modification sync

Amazon S3 replica modification sync can help you keep object metadata such as tags, ACLs, and Object Lock settings replicated between replicas and source objects. By default, Amazon S3 replicates metadata from the source objects to the replicas only. When replica modification sync is enabled, Amazon S3 replicates metadata changes made to the replica copies back to the source object, making the replication bidirectional.

Enabling replica modification sync

You can use Amazon S3 replica modification sync with new or existing replication rules. You can apply it to an entire S3 bucket or to Amazon S3 objects that have a specific prefix.

To enable replica modification sync using the Amazon S3 console, see [Walkthroughs: Examples for configuring replication](#). This topic provides instructions for enabling replica modification sync in your replication configuration when buckets are owned by the same or different AWS accounts.

To enable replica modification sync using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the bucket containing the replicas with `ReplicaModifications` enabled. To set up two-way replication, create a replication rule from the source bucket (`DOC-EXAMPLE-BUCKET1`) to the bucket containing the replicas (`DOC-EXAMPLE-BUCKET2`). Then, create a second replication rule from the bucket containing the replicas (`DOC-EXAMPLE-BUCKET2`) to the source bucket (`DOC-EXAMPLE-BUCKET1`). Buckets can be in the same, or in different, AWS Regions.

Note

You must enable replica modification sync on both buckets to replicate replica metadata changes like object access control lists (ACLs), object tags, or Object Lock settings on the

replicated objects. Like all replication rules, these rules can either be applied to the entire Amazon S3 bucket or a subset of Amazon S3 objects filtered by prefix or object tags.

In the following example configuration, Amazon S3 replicates metadata changes under the prefix *Tax* to the bucket *DOC-EXAMPLE-BUCKET*, which would contain the source objects.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "SourceSelectionCriteria": {  
                "ReplicaModifications": {  
                    "Status": "Enabled"  
                }  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::DOC-EXAMPLE-BUCKET"  
            },  
            "Priority": 1  
        }  
    "Role": "IAM-Role-ARN"  
}
```

For full instructions on creating replication rules using the AWS CLI, see [Configuring replication for source and destination buckets owned by the same account](#).

Changing the replica owner

In replication, the owner of the source object also owns the replica by default. When source and destination buckets are owned by different AWS accounts and you want to change replica ownership to the AWS account that owns the destination buckets, you can add optional configuration settings to change replica ownership to the AWS account that owns the destination buckets. You might do this, for example, to restrict access to object replicas. This is referred to as the *owner override* option of the replication configuration. For more information about the owner override option, see [Adding the owner override option to the replication configuration](#). For information about setting the replication configuration, see [Replicating objects](#).

To configure the owner override, you do the following:

- Add the owner override option to the replication configuration to tell Amazon S3 to change replica ownership.
- Grant Amazon S3 permissions to change replica ownership.
- Add permission in the destination buckets policy to allow changing replica ownership. This allows the owner of the destination buckets to accept the ownership of object replicas.

For more information, see [Adding the owner override option to the replication configuration](#). For a working example with step-by-step instructions, see [Changing the replica owner when source and destination buckets are owned by different accounts](#).

Bucket owner enforced setting for Object Ownership

When you use Amazon S3 replication and the source and destination buckets are owned by different AWS accounts, the bucket owner of the destination bucket can disable ACLs (with the bucket owner enforced setting for Object Ownership) to change replica ownership to the AWS account that owns the destination bucket. This setting mimics the existing owner override behavior without the need of `s3:ObjectOwnerOverrideToBucketOwner` permission. This means that all objects that are replicated to the destination bucket with the bucket owner enforced setting are owned by the destination bucket owner. For more information about Object Ownership, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Adding the owner override option to the replication configuration

Warning

Add the owner override option only when the source and destination buckets are owned by different AWS accounts. Amazon S3 doesn't check if the buckets are owned by same or different accounts. If you add the owner override when both buckets are owned by same AWS account, Amazon S3 applies the owner override. It grants full permissions to the owner of the destination bucket and doesn't replicate subsequent updates to the source object access control list (ACL). The replica owner can directly change the ACL associated with a replica with a `PUT` ACL request, but not through replication.

To specify the owner override option, add the following to each `Destination` element:

- The AccessControlTranslation element, which tells Amazon S3 to change replica ownership
- The Account element, which specifies the AWS account of the destination bucket owner

```
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  ...
  <Destination>
    ...
    <AccessControlTranslation>
      <Owner>Destination</Owner>
    </AccessControlTranslation>
    <Account>destination-bucket-owner-account-id</Account>
  </Destination>
</Rule>
</ReplicationConfiguration>
```

The following example replication configuration tells Amazon S3 to replicate objects that have the Tax key prefix to the destination bucket and change ownership of the replicas.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <ID>Rule-1</ID>
    <Priority>1</Priority>
    <Status>Enabled</Status>
    <DeleteMarkerReplication>
      <Status>Disabled</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Destination>
      <Bucket>arn:aws:s3:::destination-bucket</Bucket>
      <Account>destination-bucket-owner-account-id</Account>
      <AccessControlTranslation>
        <Owner>Destination</Owner>
      </AccessControlTranslation>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

Granting Amazon S3 permission to change replica ownership

Grant Amazon S3 permissions to change replica ownership by adding permission for the `s3:ObjectOwnerOverrideToBucketOwner` action in the permissions policy associated with the IAM role. This is the IAM role that you specified in the replication configuration that allows Amazon S3 to assume and replicate objects on your behalf.

```
...
{
  "Effect": "Allow",
  "Action": [
    "s3:ObjectOwnerOverrideToBucketOwner"
  ],
  "Resource": "arn:aws:s3:::destination-bucket/*"
}
...
```

Adding permission in the destination bucket policy to allow changing replica ownership

The owner of the destination bucket must grant the owner of the source bucket permission to change replica ownership. The owner of the destination bucket grants the owner of the source bucket permission for the `s3:ObjectOwnerOverrideToBucketOwner` action. This allows the destination bucket owner to accept ownership of the object replicas. The following example bucket policy statement shows how to do this.

```
...
{
  "Sid": "1",
  "Effect": "Allow",
  "Principal": {"AWS": "source-bucket-account-id" },
  "Action": ["s3:ObjectOwnerOverrideToBucketOwner"],
  "Resource": "arn:aws:s3:::destination-bucket/*"
}
...
```

Additional considerations

When you configure the ownership override option, the following considerations apply:

- By default, the owner of the source object also owns the replica. Amazon S3 replicates the object version and the ACL associated with it.

If you add the owner override, Amazon S3 replicates only the object version, not the ACL. In addition, Amazon S3 doesn't replicate subsequent changes to the source object ACL. Amazon S3 sets the ACL on the replica that grants full control to the destination bucket owner.

- When you update a replication configuration to enable, or disable, the owner override, the following occurs.

- If you add the owner override option to the replication configuration:

When Amazon S3 replicates an object version, it discards the ACL that is associated with the source object. Instead, it sets the ACL on the replica, giving full control to the owner of the destination bucket. It doesn't replicate subsequent changes to the source object ACL. However, this ACL change doesn't apply to object versions that were replicated before you set the owner override option. ACL updates on source objects that were replicated before the owner override was set continue to be replicated (because the object and its replicas continue to have the same owner).

- If you remove the owner override option from the replication configuration:

Amazon S3 replicates new objects that appear in the source bucket and the associated ACLs to the destination buckets. For objects that were replicated before you removed the owner override, Amazon S3 doesn't replicate the ACLs because the object ownership change that Amazon S3 made remains in effect. That is, ACLs put on the object version that were replicated when the owner override was set continue to be not replicated.

Replicating objects created with server-side encryption (SSE-C, SSE-S3, SSE-KMS, DSSE-KMS)

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API

response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

There are some special considerations when you're replicating objects that have been encrypted by using server-side encryption. Amazon S3 supports the following types of server-side encryption:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

For more information about server-side encryption, see [the section called “Server-side encryption”](#).

This topic explains the permissions that you need to direct Amazon S3 to replicate objects that have been encrypted by using server-side encryption. This topic also provides additional configuration elements that you can add and example AWS Identity and Access Management (IAM) policies that grant the necessary permissions for replicating encrypted objects.

For an example with step-by-step instructions, see [Replicating encrypted objects](#). For information about creating a replication configuration, see [Replicating objects](#).

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys in AWS Key Management Service Developer Guide](#).

Topics

- [How default bucket encryption affects replication](#)
- [Replicating objects encrypted with SSE-C](#)
- [Replicating objects encrypted with SSE-S3, SSE-KMS, or DSSE-KMS](#)

How default bucket encryption affects replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.
- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

Replicating objects encrypted with SSE-C

By using server-side encryption with customer-provided keys (SSE-C), you can manage proprietary encryption keys. With SSE-C, you manage the keys while Amazon S3 manages the encryption and decryption process. You must provide an encryption key as part of your request, but you don't need to write any code to perform object encryption or decryption. When you upload an object, Amazon S3 encrypts the object by using the key that you provided. Amazon S3 then purges that key from memory. When you retrieve an object, you must provide the same encryption key as part of your request. For more information, see [the section called "Customer-provided encryption keys \(SSE-C\)".](#)

S3 Replication supports objects that are encrypted with SSE-C. You can configure SSE-C object replication in the Amazon S3 console or with the AWS SDKs, the same way that you configure replication for unencrypted objects. There aren't additional SSE-C permissions beyond what are currently required for replication.

S3 Replication automatically replicates newly uploaded SSE-C encrypted objects if they are eligible, as specified in your S3 Replication configuration. To replicate existing objects in your buckets, use S3 Batch Replication. For more information about replicating objects, see [the section called "Setting up replication"](#) and [the section called "Replicate existing objects".](#)

There are no additional charges for replicating SSE-C objects. For details about replication pricing, see the [Amazon S3 pricing page](#).

Replicating objects encrypted with SSE-S3, SSE-KMS, or DSSE-KMS

By default, Amazon S3 doesn't replicate objects that are encrypted with SSE-KMS or DSSE-KMS. This section explains the additional configuration elements that you can add to direct Amazon S3 to replicate these objects.

For an example with step-by-step instructions, see [Replicating encrypted objects](#). For information about creating a replication configuration, see [Replicating objects](#).

Specifying additional information in the replication configuration

In the replication configuration, you do the following:

- In the `Destination` element in your replication configuration, add the ID of the symmetric AWS KMS customer managed key that you want Amazon S3 to use to encrypt object replicas, as shown in the following example replication configuration.
- Explicitly opt in by enabling replication of objects encrypted by using KMS keys (SSE-KMS or DSSE-KMS). To opt in, add the `SourceSelectionCriteria` element, as shown in the following example replication configuration.

```
<ReplicationConfiguration>
  <Rule>
    ...
    <SourceSelectionCriteria>
      <SseKmsEncryptedObjects>
        <Status>Enabled</Status>
      </SseKmsEncryptedObjects>
    </SourceSelectionCriteria>

    <Destination>
      ...
      <EncryptionConfiguration>
        <ReplicaKmsKeyID>AWS KMS key ARN or Key Alias ARN that's in the same AWS Region as the destination bucket.</ReplicaKmsKeyID>
      </EncryptionConfiguration>
    </Destination>
    ...
  </Rule>
</ReplicationConfiguration>
```

⚠ Important

The KMS key must have been created in the same AWS Region as the destination buckets. The KMS key *must* be valid. The PutBucketReplication API operation doesn't check the validity of KMS keys. If you use a KMS key that isn't valid, you will receive the HTTP 200 OK status code in response, but replication fails.

The following example shows a replication configuration that includes optional configuration elements. This replication configuration has one rule. The rule applies to objects with the Tax key prefix. Amazon S3 uses the specified AWS KMS key ID to encrypt these object replicas.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration>
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <ID>Rule-1</ID>
    <Priority>1</Priority>
    <Status>Enabled</Status>
    <DeleteMarkerReplication>
      <Status>Disabled</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Destination>
      <Bucket>arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET</Bucket>
      <EncryptionConfiguration>
        <ReplicaKmsKeyId>AWS KMS key ARN or Key Alias ARN that's in the same AWS Region as the destination bucket. (S3 uses this key to encrypt object replicas.)</ReplicaKmsKeyId>
        </EncryptionConfiguration>
      </Destination>
      <SourceSelectionCriteria>
        <SseKmsEncryptedObjects>
          <Status>Enabled</Status>
        </SseKmsEncryptedObjects>
      </SourceSelectionCriteria>
    </Rule>
  </ReplicationConfiguration>
```

Granting additional permissions for the IAM role

To replicate objects that are encrypted at rest by using SSE-S3, SSE-KMS, or DSSE-KMS, grant the following additional permissions to the AWS Identity and Access Management (IAM) role that you specify in the replication configuration. You grant these permissions by updating the permissions policy that's associated with the IAM role.

- **s3:GetObjectVersionForReplication action for source objects** – This action allows Amazon S3 to replicate both unencrypted objects and objects created with server-side encryption by using SSE-S3, SSE-KMS, or DSSE-KMS.

 **Note**

We recommend that you use the `s3:GetObjectVersionForReplication` action instead of the `s3:GetObjectVersion` action because `s3:GetObjectVersionForReplication` provides Amazon S3 with only the minimum permissions necessary for replication. In addition, the `s3:GetObjectVersion` action allows replication of unencrypted and SSE-S3-encrypted objects, but not of objects that are encrypted by using KMS keys (SSE-KMS or DSSE-KMS).

- **kms:Decrypt and kms:Encrypt AWS KMS actions for the KMS keys**

- You must grant `kms:Decrypt` permissions for the AWS KMS key that's used to decrypt the source object.
- You must grant `kms:Encrypt` permissions for the AWS KMS key that's used to encrypt the object replica.
- **kms:GenerateDataKey action for replicating plaintext objects** – If you're replicating plaintext objects to a bucket with SSE-KMS or DSSE-KMS encryption enabled by default, you must include the `kms:GenerateDataKey` permission for the destination encryption context and the KMS key in the IAM policy.

We recommend that you restrict these permissions only to the destination buckets and objects by using AWS KMS condition keys. The AWS account that owns the IAM role must have permissions for the `kms:Encrypt` and `kms:Decrypt` actions for the KMS keys that are listed in the policy. If the KMS keys are owned by another AWS account, the owner of the KMS keys must grant these permissions to the AWS account that owns the IAM role. For more information about managing access to these KMS keys, see [Using IAM Policies with AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

S3 Bucket Keys and replication

To use replication with an S3 Bucket Key, the AWS KMS key policy for the KMS key that's used to encrypt the object replica must include the `kms:Decrypt` permission for the calling principal. The call to `kms:Decrypt` verifies the integrity of the S3 Bucket Key before using it. For more information, see [Using an S3 Bucket Key with replication](#).

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket's Amazon Resource Name (ARN), not the object's ARN (for example, `arn:aws:s3:::bucket_ARN`). You must update your IAM policies to use the bucket ARN for the encryption context:

```
"kms:EncryptionContext:aws:s3:arn": [
    "arn:aws:s3:::bucket_ARN"
]
```

For more information, see [Encryption context \(x-amz-server-side-encryption-context\)](#) (in the "Using the REST API" section) and [Changes to note before enabling an S3 Bucket Key](#).

Example policies – Using SSE-S3 and SSE-KMS with replication

The following example IAM policies show statements for using SSE-S3 and SSE-KMS with replication.

Example – Using SSE-KMS with separate destination buckets

The following example policy shows statements for using SSE-KMS with separate destination buckets.

```
{
    "Action": ["kms:Decrypt"],
    "Effect": "Allow",
    "Condition": {
        "StringLike": {
            "kms:ViaService": "s3.source-bucket-region.amazonaws.com",
            "kms:EncryptionContext:aws:s3:arn": [
                "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET/key-prefix1*"
            ]
        }
    },
    "Resource": [
        "List of AWS KMS key ARNs that are used to encrypt source objects."
    ]
}
```

```
],
},
{
  "Action": ["kms:Encrypt"],
  "Effect": "Allow",
  "Condition": {
    "StringLike": {
      "kms:ViaService": "s3.destination-bucket-1-region.amazonaws.com",
      "kms:EncryptionContext:aws:s3:arn": [
        "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET1/key-prefix1*"
      ]
    }
  },
  "Resource": [
    "AWS KMS key ARNs (in the same AWS Region as destination bucket 1). Used to
    encrypt object replicas created in destination bucket 1."
  ]
},
{
  "Action": ["kms:Encrypt"],
  "Effect": "Allow",
  "Condition": {
    "StringLike": {
      "kms:ViaService": "s3.destination-bucket-2-region.amazonaws.com",
      "kms:EncryptionContext:aws:s3:arn": [
        "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET2/key-prefix1*"
      ]
    }
  },
  "Resource": [
    "AWS KMS key ARNs (in the same AWS Region as destination bucket 2). Used to
    encrypt object replicas created in destination bucket 2."
  ]
}
```

Example – Replicating objects created with SSE-S3 and SSE-KMS

The following is a complete IAM policy that grants the necessary permissions to replicate unencrypted objects, objects created with SSE-S3, and objects created with SSE-KMS.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:GetReplicationConfiguration",  
        "s3>ListBucket"  
    ],  
    "Resource": [  
        "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"  
    ]  
},  
{  
    "Effect": "Allow",  
    "Action": [  
        "s3GetObjectVersionForReplication",  
        "s3GetObjectVersionAcl"  
    ],  
    "Resource": [  
        "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET/key-prefix1*"  
    ]  
},  
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:ReplicateObject",  
        "s3:ReplicateDelete"  
    ],  
    "Resource": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/key-prefix1*"  
},  
{  
    "Action": [  
        "kms:Decrypt"  
    ],  
    "Effect": "Allow",  
    "Condition": {  
        "StringLike": {  
            "kms:ViaService": "s3.source-bucket-region.amazonaws.com",  
            "kms:EncryptionContext:aws:s3:arn": [  
                "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET/key-prefix1*"  
            ]  
        }  
    },  
    "Resource": [  
        "List of the AWS KMS key ARNs that are used to encrypt source objects."  
    ]  
}
```

```
},
{
  "Action": [
    "kms:Encrypt"
  ],
  "Effect": "Allow",
  "Condition": {
    "StringLike": {
      "kms:ViaService": "s3.destination-bucket-region.amazonaws.com",
      "kms:EncryptionContext:aws:s3:arn": [
        "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/prefix1*"
      ]
    }
  },
  "Resource": [
    "AWS KMS key ARNs (in the same AWS Region as the destination bucket) to use
for encrypting object replicas"
  ]
}
]
```

Example – Replicating objects with S3 Bucket Keys

The following is a complete IAM policy that grants the necessary permissions to replicate objects with S3 Bucket Keys.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetReplicationConfiguration",
        "s3>ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [

```

```
        "s3:GetObjectVersionForReplication",
        "s3:GetObjectVersionAcl"
    ],
    "Resource": [
        "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET/key-prefix1*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:ReplicateObject",
        "s3:ReplicateDelete"
    ],
    "Resource": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/key-prefix1*"
},
{
    "Action": [
        "kms:Decrypt"
    ],
    "Effect": "Allow",
    "Condition": {
        "StringLike": {
            "kms:ViaService": "s3.source-bucket-region.amazonaws.com",
            "kms:EncryptionContext:aws:s3:arn": [
                "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"
            ]
        }
    },
    "Resource": [
        "List of the AWS KMS key ARNs that are used to encrypt source objects.""
    ]
},
{
    "Action": [
        "kms:Encrypt"
    ],
    "Effect": "Allow",
    "Condition": {
        "StringLike": {
            "kms:ViaService": "s3.destination-bucket-region.amazonaws.com",
            "kms:EncryptionContext:aws:s3:arn": [
                "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET"
            ]
        }
    }
}
```

```
    },
    "Resource": [
        "AWS KMS key ARNs (in the same AWS Region as the destination bucket) to use
        for encrypting object replicas"
    ]
}
]
```

Granting additional permissions for cross-account scenarios

In a cross-account scenario, where the source and destination buckets are owned by different AWS accounts, you can use a KMS key to encrypt object replicas. However, the KMS key owner must grant the source bucket owner permission to use the KMS key.

Note

Objects encrypted through [AWS managed keys](#) cannot be shared cross-account because you cannot modify the key policies. If you need to replicate SSE-KMS data cross-account, you must use a [customer managed key](#) from AWS KMS.

To grant the source bucket owner permission to use the KMS key (AWS KMS console)

1. Sign in to the AWS Management Console and open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**.
4. Choose the KMS key.
5. Under the **General configuration** section, choose the **Key policy** tab.
6. Scroll down to **Other AWS accounts**.
7. Choose **Add other AWS accounts**.

The **Other AWS accounts** dialog box appears.

8. In the dialog box, choose **Add another AWS account**. For **arn:aws:iam::**, enter the source bucket account ID.

9. Choose **Save changes**.

To grant the source bucket owner permission to use the KMS key (AWS CLI)

- For information about the put-key-policy AWS Command Line Interface (AWS CLI) command, see [put-key-policy](#) in the *AWS CLI Command Reference*. For information about the underlying PutKeyPolicy API operation, see [PutKeyPolicy](#) in the [AWS Key Management Service API Reference](#).

AWS KMS transaction quota considerations

When you add many new objects with AWS KMS encryption after enabling Cross-Region Replication (CRR), you might experience throttling (HTTP 503 Service Unavailable errors). Throttling occurs when the number of AWS KMS transactions per second exceeds the current quota. For more information, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

To request a quota increase, use Service Quotas. For more information, see [Requesting a quota increase](#). If Service Quotas isn't supported in your Region, [open an AWS Support case](#).

Getting replication status information

Replication status can help you determine the current state of an object being replicated. The replication status of a source object will return either PENDING, COMPLETED, or FAILED. The replication status of a replica will return REPLICA.

Topics

- [Replication status overview](#)
- [Replication status if replicating to multiple destination buckets](#)
- [Replication status if Amazon S3 replica modification sync is enabled](#)
- [Finding replication status](#)

Replication status overview

In replication, you have a source bucket on which you configure replication and destination where Amazon S3 replicates objects. When you request an object (using GET object) or object metadata (using HEAD object) from these buckets, Amazon S3 returns the x-amz-replication-status header in the response:

- When you request an object from the source bucket, Amazon S3 returns the `x-amz-replication-status` header if the object in your request is eligible for replication.

For example, suppose that you specify the object prefix `TaxDocs` in your replication configuration to tell Amazon S3 to replicate only objects with the key name prefix `TaxDocs`. Any objects that you upload that have this key name prefix—for example, `TaxDocs/document1.pdf`—will be replicated. For object requests with this key name prefix, Amazon S3 returns the `x-amz-replication-status` header with one of the following values for the object's replication status: `PENDING`, `COMPLETED`, or `FAILED`.

 **Note**

If object replication fails after you upload an object, you can't retry replication. You must upload the object again. Objects transition to a `FAILED` state for issues such as missing replication role permissions, AWS KMS permissions, or bucket permissions. For temporary failures, such as if a bucket or Region is unavailable, replication status will not transition to `FAILED`, but will remain `PENDING`. After the resource is back online, S3 will resume replicating those objects.

- When you request an object from a destination bucket, if the object in your request is a replica that Amazon S3 created, Amazon S3 returns the `x-amz-replication-status` header with the value `REPLICA`.

 **Note**

Before deleting an object from a source bucket that has replication enabled, check the object's replication status to ensure that the object has been replicated.

If lifecycle configuration is enabled on the source bucket, Amazon S3 suspends lifecycle actions until it marks the objects status as either `COMPLETED` or `FAILED`.

Replication status if replicating to multiple destination buckets

When you replicate objects to multiple destination buckets, the `x-amz-replication-status` header acts differently. The header of the source object only returns a value of `COMPLETED` when replication is successful to all destinations. The header remains at the `PENDING` value until

replication has completed for all destinations. If one or more destinations fail replication, the header returns FAILED.

Replication status if Amazon S3 replica modification sync is enabled

When your replication rules enable Amazon S3 replica modification sync, replicas can report statuses other than REPLICA. If metadata changes are in the process of replicating, the `x-amz-replication-status` header returns PENDING. If replica modification sync fails to replicate metadata, the header returns FAILED. If metadata is replicated correctly, the replicas return the header REPLICA.

Finding replication status

To get the replication status of the objects in a bucket, you can use the Amazon S3 Inventory tool. Amazon S3 sends a CSV file to the destination bucket that you specify in the inventory configuration. You can also use Amazon Athena to query the replication status in the inventory report. For more information about Amazon S3 Inventory, see [Amazon S3 Inventory](#).

You can also find the object replication status using the console, the AWS Command Line Interface (AWS CLI), or the AWS SDK.

Using the S3 console

In the S3 console, you can view the replication status for an object on the object **Details** page under **Object management overview**.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket name.
3. In the **Objects** list, choose the object name.
4. Under the **Properties** tab find **Object management overview**, here you can see the **Replication status**.

Using the AWS CLI

Use the `head-object` command to retrieve object metadata, as follows.

```
aws s3api head-object --bucket source-bucket --key object-key --version-id object-version-id
```

The command returns object metadata, including the `ReplicationStatus` as shown in the following example response.

```
{  
    "AcceptRanges": "bytes",  
    "ContentType": "image/jpeg",  
    "LastModified": "Mon, 23 Mar 2015 21:02:29 GMT",  
    "ContentLength": 3191,  
    "ReplicationStatus": "COMPLETED",  
    "VersionId": "jfNw.HIM0fYiD_9rGbSkmroXsFj3fqZ.",  
    "ETag": "\"6805f2fc46c0f04559748bb039d69ae\"",  
    "Metadata": {  
    }  
}
```

Using the AWS SDKs

The following code fragments get replication status with the AWS SDK for Java and AWS SDK for .NET, respectively.

Java

```
GetObjectMetadataRequest metadataRequest = new GetObjectMetadataRequest(bucketName,  
    key);  
ObjectMetadata metadata = s3Client.getObjectMetadata(metadataRequest);  
  
System.out.println("Replication Status : " +  
    metadata.getRawMetadataValue(Headers.OBJECT_REPLICATION_STATUS));
```

.NET

```
GetObjectMetadataRequest getmetadataRequest = new GetObjectMetadataRequest  
{  
    BucketName = sourceBucket,  
    Key        = objectKey  
};  
  
GetObjectMetadataResponse getmetadataResponse =  
    client.GetObjectMetadata(getmetadataRequest);  
Console.WriteLine("Object replication status: {0}",  
    getmetadataResponse.ReplicationStatus);
```

Additional considerations

Amazon S3 also supports bucket configurations for the following:

- Versioning – For more information, see [Using versioning in S3 buckets](#).
- Website hosting – For more information, see [Hosting a static website using Amazon S3](#).
- Bucket access through a bucket policy or access control list (ACL) — For more information, see [Bucket policies and user policies](#) and see [Access control list \(ACL\) overview](#).
- Log storage – For more information, [Logging requests with server access logging](#).
- Lifecycle management for objects in a bucket – For more information, see [Managing your storage lifecycle](#).

This topic explains how bucket replication configuration affects the behavior of these bucket configurations.

Topics

- [Lifecycle configuration and object replicas](#)
- [Versioning configuration and replication configuration](#)
- [Using S3 Replication with S3 Intelligent-Tiering](#)
- [Logging configuration and replication configuration](#)
- [CRR and the destination Region](#)
- [Pausing replication](#)

Lifecycle configuration and object replicas

The time it takes for Amazon S3 to replicate an object depends on the size of the object. For large objects, it can take several hours. Although it might take a while before a replica is available in the destination, it takes the same amount of time to create the replica as it took to create the corresponding object in the source bucket. If a lifecycle configuration is enabled on a destination bucket, the lifecycle rules honor the original creation time of the object, not when the replica became available in the destination bucket.

Replication configuration requires the bucket to be versioning-enabled. When you enable versioning on a bucket, keep the following in mind:

- If you have an object Expiration lifecycle configuration, after you enable versioning, add a NonCurrentVersionExpiration policy to maintain the same permanent delete behavior as before you enabled versioning.
- If you have a Transition lifecycle configuration, after you enable versioning, consider adding a NonCurrentVersionTransition policy.

Versioning configuration and replication configuration

Both the source and destination buckets must be versioning-enabled when you configure replication on a bucket. After you enable versioning on both the source and destination buckets and configure replication on the source bucket, you will encounter the following issues:

- If you attempt to disable versioning on the source bucket, Amazon S3 returns an error. You must remove the replication configuration before you can disable versioning on the source bucket.
- If you disable versioning on the destination bucket, replication fails. The source object has the replication status FAILED.

Using S3 Replication with S3 Intelligent-Tiering

S3 Intelligent-Tiering is a storage class that is designed to optimize storage costs by automatically moving data to the most cost-effective access tier. For a small monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers.

Replicating objects stored in S3 Intelligent-Tiering with S3 Batch Replication or invoking [CopyObject](#) or [UploadPartCopy](#) constitutes access. In these cases, the source objects of the copy or replication operations are tiered up.

For more information about S3 Intelligent-Tiering see, [Amazon S3 Intelligent-Tiering](#).

Logging configuration and replication configuration

If Amazon S3 delivers logs to a bucket that has replication enabled, it replicates the log objects.

If server access logs ([Logging requests with server access logging](#)) or AWS CloudTrail logs ([Logging Amazon S3 API calls using AWS CloudTrail](#)) are enabled on your source or destination bucket, Amazon S3 includes replication-related requests in the logs. For example, Amazon S3 logs each object that it replicates.

CRR and the destination Region

Amazon S3 Cross-Region Replication (CRR) is used to copy objects across S3 buckets in different AWS Regions. You might choose the Region for your destination bucket based on either your business needs or cost considerations. For example, inter-Region data transfer charges vary depending on the Regions that you choose.

Suppose that you chose US East (N. Virginia) (us-east-1) as the Region for your source bucket. If you choose US West (Oregon) (us-west-2) as the Region for your destination buckets, you pay more than if you choose the US East (Ohio) (us-east-2) Region. For pricing information, see "Data Transfer Pricing" in [Amazon S3 pricing](#).

There are no data transfer charges associated with Same-Region Replication (SRR).

Pausing replication

To temporarily pause replication, disable the relevant rule in the replication configuration.

If replication is enabled and you remove the IAM role that grants Amazon S3 the required permissions, replication fails. Amazon S3 reports the replication status for affected objects as FAILED.

Categorizing your storage using tags

Use object tagging to categorize storage. Each tag is a key-value pair.

You can add tags to new objects when you upload them, or you can add them to existing objects.

- You can associate up to 10 tags with an object. Tags that are associated with an object must have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length. Amazon S3 object tags are internally represented in UTF-16. Note that in UTF-16, characters consume either 1 or 2 character positions.
- The key and values are case sensitive.
- For more information about tag restrictions, see [User-Defined Tag Restrictions](#).

Examples

Consider the following tagging examples:

Example PHI information

Suppose that an object contains protected health information (PHI) data. You might tag the object using the following key-value pair.

```
PHI=True
```

or

```
Classification=PHI
```

Example Project files

Suppose that you store project files in your S3 bucket. You might tag these objects with a key named Project and a value, as shown following.

```
Project=Blue
```

Example Multiple tags

You can add multiple tags to an object, as shown following.

```
Project=x  
Classification=confidential
```

Key name prefixes and tags

Object key name prefixes also enable you to categorize storage. However, prefix-based categorization is one-dimensional. Consider the following object key names:

```
photos/photo1.jpg  
project/projectx/document.pdf  
project/projecty/document2.pdf
```

These key names have the prefixes photos/, project/projectx/, and project/projecty/. These prefixes enable one-dimensional categorization. That is, everything under a prefix is one category. For example, the prefix project/projectx identifies all documents related to project x.

With tagging, you now have another dimension. If you want photo1 in project x category, you can tag the object accordingly.

Additional benefits

In addition to data classification, tagging offers benefits such as the following:

- Object tags enable fine-grained access control of permissions. For example, you could grant a user permissions to read-only objects with specific tags.
- Object tags enable fine-grained object lifecycle management in which you can specify a tag-based filter, in addition to a key name prefix, in a lifecycle rule.
- When using Amazon S3 analytics, you can configure filters to group objects together for analysis by object tags, by key name prefix, or by both prefix and tags.
- You can also customize Amazon CloudWatch metrics to display information by specific tag filters. The following sections provide details.

Important

It is acceptable to use tags to label objects containing confidential data, such as personally identifiable information (PII) or protected health information (PHI). However, the tags themselves shouldn't contain any confidential information.

Adding object tag sets to multiple Amazon S3 object with a single request

To add object tag sets to more than one Amazon S3 object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

The S3 Batch Operations feature tracks progress, sends notifications, and stores a detailed completion report of all actions, providing a fully managed, auditable, serverless experience. You can use S3 Batch Operations through the Amazon S3 console, AWS CLI, AWS SDKs, or REST API. For more information, see [the section called “Batch Operations basics”](#).

For more information about object tags, see [Managing object tags](#).

API operations related to object tagging

Amazon S3 supports the following API operations that are specifically for object tagging:

Object API operations

- [PUT Object tagging](#) – Replaces tags on an object. You specify tags in the request body. There are two distinct scenarios of object tag management using this API.

- Object has no tags – Using this API you can add a set of tags to an object (the object has no prior tags).
- Object has a set of existing tags – To modify the existing tag set, you must first retrieve the existing tag set, modify it on the client side, and then use this API to replace the tag set.

 **Note**

If you send this request with an empty tag set, Amazon S3 deletes the existing tag set on the object. If you use this method, you will be charged for a Tier 1 Request (PUT).

For more information, see [Amazon S3 Pricing](#).

The [DELETE Object tagging](#) request is preferred because it achieves the same result without incurring charges.

- [GET Object tagging](#) – Returns the tag set associated with an object. Amazon S3 returns object tags in the response body.
- [DELETE Object tagging](#) – Deletes the tag set associated with an object.

Other API operations that support tagging

- [PUT Object](#) and [Initiate Multipart Upload](#) – You can specify tags when you create objects. You specify tags using the x-amz-tagging request header.
- [GET Object](#) – Instead of returning the tag set, Amazon S3 returns the object tag count in the x-amz-tag-count header (only if the requester has permissions to read tags) because the header response size is limited to 8 K bytes. If you want to view the tags, you make another request for the [GET Object tagging](#) API operation.
- [POST Object](#) – You can specify tags in your POST request.

As long as the tags in your request don't exceed the 8 K byte HTTP request header size limit, you can use the PUT Object API to create objects with tags. If the tags you specify exceed the header size limit, you can use this POST method in which you include the tags in the body.

[PUT Object - Copy](#) – You can specify the `x-amz-tagging-directive` in your request to direct Amazon S3 to either copy (default behavior) the tags or replace tags by a new set of tags provided in the request.

Note the following:

- S3 Object Tagging is strongly consistent. For more information, see [Amazon S3 data consistency model](#).

Additional configurations

This section explains how object tagging relates to other configurations.

Object tagging and lifecycle management

In bucket lifecycle configuration, you can specify a filter to select a subset of objects to which the rule applies. You can specify a filter based on the key name prefixes, object tags, or both.

Suppose that you store photos (raw and the finished format) in your Amazon S3 bucket. You might tag these objects as shown following.

```
phototype=raw  
or  
phototype=finished
```

You might consider archiving the raw photos to S3 Glacier sometime after they are created. You can configure a lifecycle rule with a filter that identifies the subset of objects with the key name prefix (`photos/`) that have a specific tag (`phototype=raw`).

For more information, see [Managing your storage lifecycle](#).

Object tagging and replication

If you configured Replication on your bucket, Amazon S3 replicates tags, provided you grant Amazon S3 permission to read the tags. For more information, see [Setting up replication](#).

Object tagging event notifications

You can set up an Amazon S3 event notification to receive notice when an object tag is added or deleted from an object. The `s3:ObjectTagging:Put` event type notifies you when a tag is PUT on an object or when an existing tag is updated. The `s3:ObjectTagging:Delete` event type notifies you when a tag is removed from an object. For more information, see [Enabling event notifications](#).

For more information about object tagging, see the following topics:

Topics

- [Tagging and access control policies](#)
- [Managing object tags](#)

Tagging and access control policies

You can also use permissions policies (bucket and user policies) to manage permissions related to object tagging. For policy actions see the following topics:

- [Example — Object operations](#)
- [Example — Bucket operations](#)

Object tags enable fine-grained access control for managing permissions. You can grant conditional permissions based on object tags. Amazon S3 supports the following condition keys that you can use to grant conditional permissions based on object tags:

- `s3:ExistingObjectTag/<tag-key>` – Use this condition key to verify that an existing object tag has the specific tag key and value.

 **Note**

When granting permissions for the `PUT Object` and `DELETE Object` operations, this condition key is not supported. That is, you cannot create a policy to grant or deny a user permissions to delete or overwrite an object based on its existing tags.

- `s3:RequestObjectTagKeys` – Use this condition key to restrict the tag keys that you want to allow on objects. This is useful when adding tags to objects using the `PutObjectTagging` and `PutObject`, and `POST object` requests.

- **s3:RequestObjectTag/*<tag-key>*** – Use this condition key to restrict the tag keys and values that you want to allow on objects. This is useful when adding tags to objects using the PutObjectTagging and PutObject, and POST Bucket requests.

For a complete list of Amazon S3 service-specific condition keys, see [Amazon S3 condition key examples](#). The following permissions policies illustrate how object tagging enables fine grained access permissions management.

Example 1: Allow a user to read only the objects that have a specific tag and key value

The following permissions policy limits a user to only reading objects that have the environment: production tag key and value. This policy uses the s3:ExistingObjectTag condition key to specify the tag key and value.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:role/JohnDoe"  
                ]  
            },  
            "Effect": "Allow",  
            "Action": ["s3:GetObject", "s3:GetObjectVersion"],  
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",  
            "Condition": {  
                "StringEquals":  
                    {"s3:ExistingObjectTag/environment": "production"}  
            }  
        }  
    ]  
}
```

Example 2: Restrict which object tag keys that users can add

The following permissions policy grants a user permissions to perform the s3:PutObjectTagging action, which allows user to add tags to an existing object. The condition uses the s3:RequestObjectTagKeys condition key to specify the allowed tag keys, such as Owner or CreationDate. For more information, see [Creating a condition that tests multiple key values](#) in the *IAM User Guide*.

The policy ensures that every tag key specified in the request is an authorized tag key. The ForAnyValue qualifier in the condition ensures that at least one of the specified keys must be present in the request.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {"Principal": {"AWS": [  
            "arn:aws:iam::111122223333:role/JohnDoe"  
        ]},  
        "Effect": "Allow",  
        "Action": [  
            "s3:PutObjectTagging"  
        ],  
        "Resource": [  
            "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"  
        ],  
        "Condition": {"ForAnyValue:StringEquals": {"s3:RequestObjectTagKeys": [  
            "Owner",  
            "CreationDate"  
        ]}}  
    ]  
}
```

Example 3: Require a specific tag key and value when allowing users to add object tags

The following example policy grants a user permission to perform the s3:PutObjectTagging action, which allows a user to add tags to an existing object. The condition requires the user to include a specific tag key (such as *Project*) with the value set to *X*.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {"Principal": {"AWS": [  
            "arn:aws:iam::111122223333:user/JohnDoe"  
        ]},  
        "Effect": "Allow",  
        "Condition": {"StringEquals": {"s3:RequestObjectTagKeys": ["Project"]}}
```

```
"Action": [
    "s3:PutObjectTagging"
],
"Resource": [
    "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
],
"Condition": {"StringEquals": {"s3:RequestObjectTag/Project
```

Managing object tags

This section explains how you can manage object tags using the AWS SDKs for Java and .NET or the Amazon S3 console.

Object tagging gives you a way to categorize storage. Each tag is a key-value pair that adheres to the following rules:

- You can associate up to 10 tags with an object. Tags that are associated with an object must have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length. Amazon S3 object tags are internally represented in UTF-16. Note that in UTF-16, characters consume either 1 or 2 character positions.
- The key and values are case sensitive.

For more information about object tags, see [Categorizing your storage using tags](#). For more information about tag restrictions, see [User-Defined Tag Restrictions](#) in the *AWS Billing and Cost Management User Guide*.

Using the S3 console

To add tags to an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to add tags to.

You can also optionally navigate to a folder.

3. In the **Objects** list, select the checkbox next to the names of the objects that you want to add tags to.
4. In the **Actions** menu, choose **Edit tags**.
5. Review the objects listed, and choose **Add tags**.
6. Each object tag is a key-value pair. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**.

You can enter up to 10 tags for an object.

7. Choose **Save changes**.

Amazon S3 adds the tags to the specified objects.

For more information, see also [Viewing object properties in the Amazon S3 console](#) and [Uploading objects](#) in this guide.

Using the AWS SDKs

Java

The following example shows how to use the AWS SDK for Java to set tags for a new object and retrieve or replace tags for an existing object. For more information about object tagging, see [Categorizing your storage using tags](#). For instructions on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.io.File;
import java.util.ArrayList;
```

```
import java.util.List;

public class ManagingObjectTags {

    public static void main(String[] args) {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String keyName = "*** Object key ***";
        String filePath = "*** File path ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(clientRegion)
                .build();

            // Create an object, add two new tags, and upload the object to Amazon S3.
            PutObjectRequest putRequest = new PutObjectRequest(bucketName, keyName,
new File(filePath));
            List<Tag> tags = new ArrayList<Tag>();
            tags.add(new Tag("Tag 1", "This is tag 1"));
            tags.add(new Tag("Tag 2", "This is tag 2"));
            putRequest.setTagging(new ObjectTagging(tags));
            PutObjectResult putResult = s3Client.putObject(putRequest);

            // Retrieve the object's tags.
            GetObjectTaggingRequest getTaggingRequest = new
GetObjectTaggingRequest(bucketName, keyName);
            GetObjectTaggingResult getTagsResult =
s3Client.getObjectTagging(getTaggingRequest);

            // Replace the object's tags with two new tags.
            List<Tag> newTags = new ArrayList<Tag>();
            newTags.add(new Tag("Tag 3", "This is tag 3"));
            newTags.add(new Tag("Tag 4", "This is tag 4"));
            s3Client.setObjectTagging(new SetObjectTaggingRequest(bucketName,
keyName, new ObjectTagging(newTags)));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client

```

```
        // couldn't parse the response from Amazon S3.  
        e.printStackTrace();  
    }  
}  
}
```

.NET

The following example shows how to use the AWS SDK for .NET to set the tags for a new object and retrieve or replace the tags for an existing object. For more information about object tagging, see [Categorizing your storage using tags](#).

For instructions on how to create and test a working sample, see [Running the Amazon S3 .NET Code Examples](#).

```
using Amazon;  
using Amazon.S3;  
using Amazon.S3.Model;  
using System;  
using System.Collections.Generic;  
using System.Threading.Tasks;  
  
namespace Amazon.DocSamples.S3  
{  
    public class ObjectTagsTest  
    {  
        private const string bucketName = "*** bucket name ***";  
        private const string keyName = "*** key name for the new object ***";  
        private const string filePath = @ "*** file path ***";  
        // Specify your bucket region (an example region is shown).  
        private static readonly RegionEndpoint bucketRegion =  
RegionEndpoint.USWest2;  
        private static IAmazonS3 client;  
  
        public static void Main()  
        {  
            client = new AmazonS3Client(bucketRegion);  
            PutObjectWithTagsTestAsync().Wait();  
        }  
  
        static async Task PutObjectWithTagsTestAsync()  
        {
```

```
try
{
    // 1. Put an object with tags.
    var putRequest = new PutObjectRequest
    {
        BucketName = bucketName,
        Key = keyName,
        FilePath = filePath,
        TagSet = new List<Tag>{
            new Tag { Key = "Keyx1", Value = "Value1"},
            new Tag { Key = "Keyx2", Value = "Value2" }
        }
    };

    PutObjectResponse response = await
client.PutObjectAsync(putRequest);
    // 2. Retrieve the object's tags.
    GetObjectTaggingRequest getTagsRequest = new GetObjectTaggingRequest
    {
        BucketName = bucketName,
        Key = keyName
    };

    GetObjectTaggingResponse objectTags = await
client.GetObjectTaggingAsync(getTagsRequest);
    for (int i = 0; i < objectTags.Tagging.Count; i++)
        Console.WriteLine("Key: {0}, Value: {1}",
objectTags.Tagging[i].Key, objectTags.Tagging[i].Value);

    // 3. Replace the tagset.

    Tagging newTagSet = new Tagging();
    newTagSet.TagSet = new List<Tag>{
        new Tag { Key = "Key3", Value = "Value3"},
        new Tag { Key = "Key4", Value = "Value4" }
    };

    PutObjectTaggingRequest putObjTagsRequest = new
PutObjectTaggingRequest()
    {
        BucketName = bucketName,
        Key = keyName,
```

```
        Tagging = newTagSet
    };
    PutObjectTaggingResponse response2 = await
client.PutObjectTaggingAsync(putObjTagsRequest);

    // 4. Retrieve the object's tags.
    GetObjectTaggingRequest getTagsRequest2 = new
GetObjectTaggingRequest();
    getTagsRequest2.BucketName = bucketName;
    getTagsRequest2.Key = keyName;
    GetObjectTaggingResponse objectTags2 = await
client.GetObjectTaggingAsync(getTagsRequest2);
    for (int i = 0; i < objectTags2.Tagging.Count; i++)
        Console.WriteLine("Key: {0}, Value: {1}",
objectTags2.Tagging[i].Key, objectTags2.Tagging[i].Value);

}
catch (AmazonS3Exception e)
{
    Console.WriteLine(
        "Error encountered ***. Message:'{0}' when writing an
object"
        , e.Message);
}
catch (Exception e)
{
    Console.WriteLine(
        "Encountered an error. Message:'{0}' when writing an object"
        , e.Message);
}
}
}
}
```

Using cost allocation S3 bucket tags

To track the storage cost or other criteria for individual projects or groups of projects, label your Amazon S3 buckets using cost allocation tags. A *cost allocation tag* is a key-value pair that you associate with an S3 bucket. After you activate cost allocation tags, AWS uses the tags to organize your resource costs on your cost allocation report. Cost allocation tags can only be used to label

buckets. For information about tags used for labeling objects, see [Categorizing your storage using tags](#).

The *cost allocation report* lists the AWS usage for your account by product category and linked account user. The report contains the same line items as the detailed billing report (see [Understanding your AWS billing and usage reports for Amazon S3](#)) and additional columns for your tag keys.

AWS provides two types of cost allocation tags, an AWS-generated tag and user-defined tags. AWS defines, creates, and applies the AWS-generated `createdBy` tag for you after an Amazon S3 `CreateBucket` event. You define, create, and apply *user-defined* tags to your S3 bucket.

You must activate both types of tags separately in the Billing and Cost Management console before they can appear in your billing reports. For more information about AWS-generated tags, see [AWS-Generated Cost Allocation Tags](#).

- To create tags in the console, see [Viewing the properties for an S3 bucket](#).
- To create tags using the Amazon S3 API, see [PUT Bucket tagging](#) in the *Amazon Simple Storage Service API Reference*.
- To create tags using the AWS CLI, see [put-bucket-tagging](#) in the AWS CLI Command Reference.
- For more information about activating tags, see [Using cost allocation tags](#) in the *AWS Billing User Guide*.

User-defined cost allocation tags

A user-defined cost allocation tag has the following components:

- The tag key. The tag key is the name of the tag. For example, in the tag `project/Trinity`, `project` is the key. The tag key is a case-sensitive string that can contain 1 to 128 Unicode characters.
- The tag value. The tag value is a required string. For example, in the tag `project/Trinity`, `Trinity` is the value. The tag value is a case-sensitive string that can contain from 0 to 256 Unicode characters.

For details on the allowed characters for user-defined tags and other restrictions, see [User-Defined Tag Restrictions](#) in the *AWS Billing User Guide*. For more information about user-defined tags, see [User-Defined Cost Allocation Tags](#) in the *AWS Billing User Guide*.

S3 bucket tags

Each S3 bucket has a tag set. A *tag set* contains all of the tags that are assigned to that bucket. A tag set can contain as many as 50 tags, or it can be empty. Keys must be unique within a tag set, but values in a tag set don't have to be unique. For example, you can have the same value in tag sets named project/Trinity and cost-center/Trinity.

Within a bucket, if you add a tag that has the same key as an existing tag, the new value overwrites the old value.

AWS doesn't apply any semantic meaning to your tags. We interpret tags strictly as character strings.

To add, list, edit, or delete tags, you can use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 API.

Billing and usage reporting for Amazon S3

When using Amazon S3, you don't have to pay any upfront fees or commit to how much content you'll store. Like other AWS services, you pay as you go and pay only for what you use.

AWS provides the following reports for Amazon S3:

- **Billing reports** – Multiple reports that provide high-level views of all of the activity for the AWS services that you're using, including Amazon S3. AWS always bills the owner of the S3 bucket for Amazon S3 fees, unless the bucket was created as a Requester Pays bucket. For more information about Requester Pays, see [Using Requester Pays buckets for storage transfers and usage](#). For more information about billing reports, see [AWS Billing reports for Amazon S3](#).
- **Usage report** – A summary of activity for a specific service, aggregated by hour, day, or month. You can choose which usage type and operation to include. You can also choose how the data is aggregated. For more information, see [AWS usage report for Amazon S3](#).

The following topics provide information about billing and usage reporting for Amazon S3.

- [AWS usage report for Amazon S3](#)
- [Understanding your AWS billing and usage reports for Amazon S3](#)

AWS Billing reports for Amazon S3

Your monthly bill from AWS separates your usage information and cost by AWS service and function. There are several AWS Billing reports available: the monthly report, the cost allocation report, and detailed billing reports. For information about how to see your billing reports, see [Viewing Your Bill](#) in the *AWS Billing User Guide*.

To track your AWS usage and provide estimated charges associated with your account, you can set up AWS Cost and Usage Reports. For more information, see [What are AWS Cost and Usage Reports?](#) in the *AWS Data Exports Guide*.

You can also download a usage report that gives more detail about your Amazon S3 storage usage than the billing reports. For more information, see [AWS usage report for Amazon S3](#).

The following table lists the charges associated with Amazon S3 usage.

Amazon S3 usage charges

Charge	Comments
Storage	You pay for storing objects in your S3 buckets. The rate you're charged depends on your objects' size, how long you stored the objects during the month, and the storage class. Amazon S3 offers the following storage classes: S3 Standard, S3 Express One Zone, S3 Intelligent-Tiering, S3 Standard-IA (IA for infrequent access), S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or Reduced Redundancy Storage (RRS). For more

Charge	Comments
	<p>information about storage classes, see Using Amazon S3 storage classes.</p> <p>Be aware that if you have S3 Versioning enabled, you're charged for each version of an object that is retained. For more information about versioning, see How S3 Versioning works.</p>
Monitoring and automation	You pay a monthly monitoring and automation fee per object stored in the S3 Intelligent-Tiering storage class to monitor access patterns and move objects between access tiers in S3 Intelligent-Tiering.
Requests	You pay for requests, for example, GET requests, made against your S3 buckets and objects. This includes lifecycle requests. The rates for requests depend on what kind of request you're making. For information about request pricing, see Amazon S3 Pricing .
Retrievals	You pay for retrieving objects that are stored in S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive storage.
Early deletes	If you delete an object stored in S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage before the minimum storage commitment has passed, you pay an early deletion fee for that object.

Charge	Comments
Storage management	You pay for the storage management features (Amazon S3 Inventory, analytics, and object tagging) that are enabled on your account's buckets.
Bandwidth	<p>You pay for all bandwidth into and out of Amazon S3, except for the following:</p> <ul style="list-style-type: none"><li data-bbox="838 587 1400 650">• Data transferred in from the internet<li data-bbox="838 684 1491 882">• Data transferred out to an Amazon Elastic Compute Cloud (Amazon EC2) instance, when the instance is in the same AWS Region as the S3 bucket<li data-bbox="838 916 1507 1022">• Data transferred out to Amazon CloudFront (CloudFront) <p>You also pay a fee for any data transferred by using Amazon S3 Transfer Acceleration.</p>

For detailed information about Amazon S3 usage charges for storage, data transfer, and services, see [Amazon S3 Pricing](#) and the [Amazon S3 FAQs](#).

For information about understanding the codes and abbreviations used in the billing and usage reports for Amazon S3, see [Understanding your AWS billing and usage reports for Amazon S3](#).

AWS usage report for Amazon S3

When you download a usage report, you can choose to aggregate usage data by hour, day, or month. The Amazon S3 usage report lists operations by usage type and AWS Region. For more detailed reports about your Amazon S3 storage usage, download dynamically generated AWS usage reports. You can choose which usage type, operation, and time period to include. You can also choose how the data is aggregated. For more information about usage reports, see [AWS Usage Report](#) in the *AWS Data Exports User Guide*.

The Amazon S3 usage report includes the following information:

- **Service** – Amazon S3
- **Operation** – The operation performed on your bucket or object. For a detailed explanation of Amazon S3 operations, see [Tracking Operations in Your Usage Reports](#).
- **UsageType** – One of the following values:
 - A code that identifies the type of storage
 - A code that identifies the type of request
 - A code that identifies the type of retrieval
 - A code that identifies the type of data transfer
 - A code that identifies early deletions from S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-Infrequent Access (S3 One Zone-IA), S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage
 - **StorageObjectCount** – The count of objects stored within a given bucket

For a detailed explanation of Amazon S3 usage types, see [Understanding your AWS billing and usage reports for Amazon S3](#).

- **Resource** – The name of the bucket associated with the listed usage.
- **StartTime** – Start time of the day that the usage applies to, in Coordinated Universal Time (UTC).
- **EndTime** – End time of the day that the usage applies to, in Coordinated Universal Time (UTC).
- **UsageValue** – One of the following volume values. The typical unit of measurement for data is gigabytes (GB). However, depending on the service and the report, terabytes (TB) might appear instead.
 - The number of requests during the specified time period
 - The amount of data transferred
 - The amount of data stored in a given hour

- The amount of data associated with restorations from S3 Standard-IA, S3 One Zone-IA, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage

Tip

For detailed information about every request that Amazon S3 receives for your objects, turn on server access logging for your buckets. For more information, see [Logging requests with server access logging](#).

You can download a usage report as an XML or a comma-separated values (CSV) file. The following is an example CSV usage report opened in a spreadsheet application.

Service	Operation	UsageType	Resource	StartTime	EndTime	UsageValue
AmazonS3	HeadBucket	USW2-C3DataTransfer-Out-Bytes	admin-created3	6/1/2017 0:00	7/1/2017 0:00	15309
AmazonS3	PutObject	USW2-C3DataTransfer-In-Bytes	admin-created3	6/1/2017 0:00	7/1/2017 0:00	19062
AmazonS3	HeadBucket	USW2-Requests-Tier2	admin-created3	6/1/2017 0:00	7/1/2017 0:00	68
AmazonS3	PutObjectForRepl	USW1-Requests-SIA-Tier1	ca-example-bucket	6/1/2017 0:00	7/1/2017 0:00	178294
AmazonS3	PutObjectForRepl	USW1-USW2-AWS-In-Bytes	ca-example-bucket	6/1/2017 0:00	7/1/2017 0:00	387929083
AmazonS3	GetObjectForRepl	USW2-Requests-NoCharge	admin-created3	6/1/2017 0:00	7/1/2017 0:00	108
AmazonS3	GetObjectForRepl	USW2-USW1-AWS-Out-Bytes	my-test-bucket-bash	6/1/2017 0:00	7/1/2017 0:00	387910021

For more information, see [Understanding your AWS billing and usage reports for Amazon S3](#).

Downloading the AWS Usage Report

You can download a usage report as an XML or a CSV file.

To download the usage report

- Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- In the title bar, choose your username or account ID, and then choose **Billing and Cost Management**.
- In the navigation pane, choose **Cost and usage reports**.
- Under AWS Usage Report, choose **Create a Usage Report**.
- On the **Download usage report** page, choose the following settings:
 - Services** – Choose **Amazon Simple Storage Service**.

- **Usage Types** – For a detailed explanation of Amazon S3 usage types, see [Understanding your AWS billing and usage reports for Amazon S3](#).
 - **Operation** – For a detailed explanation of Amazon S3 operations, see [Tracking Operations in Your Usage Reports](#).
 - **Time Period** – The time period that you want the report to cover.
 - **Report Granularity** – Whether you want the report to include subtotals by the hour, by the day, or by the month.
6. Choose **Download**, choose the download format (**XML Report** or **CSV Report**), and then follow the prompts to open or save the report.

Understanding your AWS billing and usage reports for Amazon S3

Amazon S3 billing and usage reports use codes and abbreviations. For usage types in the table that follows, replace *region*, *region1*, and *region2* with abbreviations from this list:

- **APE1:** Asia Pacific (Hong Kong)
- **APN1:** Asia Pacific (Tokyo)
- **APN2:** Asia Pacific (Seoul)
- **APN3:** Asia Pacific (Osaka)
- **APS1:** Asia Pacific (Singapore)
- **APS2:** Asia Pacific (Sydney)
- **APS3:** Asia Pacific (Mumbai)
- **APS4:** Asia Pacific (Jakarta)
- **APS5:** Asia Pacific (Hyderabad)
- **APS6:** Asia Pacific (Melbourne)
- **CAN1:** Canada (Central)
- **CNN1:** China (Beijing)

- **CNW1:** China (Ningxia)
- **AFS1:** Africa (Cape Town)
- **EUC2:** Europe (Zurich)
- **EUN1:** Europe (Stockholm)
- **EUS2:** Europe (Spain)
- **EUC1:** Europe (Frankfurt)
- **EU:** Europe (Ireland)
- **EUS1:** Europe (Milan)
- **EUW2:** Europe (London)
- **EUW3:** Europe (Paris)
- **ILC1:** Israel (Tel Aviv)
- **MEC1:** Middle East (UAE)
- **MES1:** Middle East (Bahrain)
- **SAE1:** South America (São Paulo)
- **UGW1:** AWS GovCloud (US-West)
- **UGE1:** AWS GovCloud (US-East)
- **USE1 (or no prefix):** US East (N. Virginia)
- **USE2:** US East (Ohio)
- **USW1:** US West (N. California)
- **USW2:** US West (Oregon)

For S3 Multi-Region Access Points usage types in the table that follows, replace *regiongroup1* and *regiongroup2* with abbreviations from this list:

- **AP:** Asia Pacific
- **AU:** Australia
- **EU:** Europe
- **IN:** India
- **NA:** North America
- **SA:** South America

Region groups are geographical groupings of several AWS Regions. For more information, see [Regions and Availability Zones](#). For information about pricing by AWS Region, see [Amazon S3 Pricing](#).

The first column in the following table lists usage types that appear in your billing and usage reports. The typical unit of measurement for data is gigabytes (GB). However, depending on the service and the report, terabytes (TB) might appear instead.

Usage Types

Usage Type	Units	Granularity	Description
<i>region1-region2</i> -AWS-In-A Bytes	GB	Hourly	The amount of accelerated data transferred to <i>region1</i> from <i>region2</i>
<i>region1-region2</i> -AWS-In-A Bytes-T1	GB	Hourly	The amount of T1 accelerated data transferred to <i>region1</i> from <i>region2</i> , where T1 refers to CloudFront requests to points of presence (POPs) in the United States, Europe, and Japan
<i>region1-region2</i> -AWS-In-A Bytes-T2	GB	Hourly	The amount of T2 accelerated data transferred to <i>region1</i> from <i>region2</i> , where T2 refers to CloudFront requests to POPs in all other AWS edge locations
<i>region1-region2</i> -AWS-In-Bytes	GB	Hourly	The amount of data transferred to <i>region1</i> from <i>region2</i>

Usage Type	Units	Granularity	Description
<i>region1-region2</i> -AWS-Out-ABytes	GB	Hourly	The amount of accelerated data transferred from <i>region1</i> to <i>region2</i>
<i>region1-region2</i> -AWS-Out-ABytes-T1	GB	Hourly	The amount of T1 accelerated data transferred from <i>region1</i> from <i>region2</i> , where T1 refers to CloudFront requests to POPs in the United States, Europe, and Japan
<i>region1-region2</i> -AWS-Out-ABytes-T2	GB	Hourly	The amount of T2 accelerated data transferred from <i>region1</i> to <i>region2</i> , where T2 refers to CloudFront requests to POPs in all other AWS edge locations
<i>region1-region2</i> -AWS-Out-Bytes	GB	Hourly	The amount of data transferred from <i>region1</i> to <i>region2</i>
<i>region</i> -BatchOperations-Jobs	Count	Hourly	The number of S3 Batch Operations jobs performed
<i>region</i> -BatchOperations-Objects	Count	Hourly	The number of object operations performed by S3 Batch Operations

Usage Type	Units	Granularity	Description
<i>region</i> -Bulk-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with Bulk S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive requests
<i>region</i> -BytesDeleted-GDA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Deep Archive storage
<i>region</i> -BytesDeleted-GIR	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -BytesDeleted-GLACIER	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Flexible Retrieval storage
<i>region</i> -BytesDeleted-INT	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
<i>region</i> -BytesDeleted-RRS	GB	Monthly	The amount of data deleted by a DeleteObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -BytesDeleted-SIA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Standard-IA storage
<i>region</i> -BytesDeleted-STANDARD	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Standard storage
<i>region</i> -BytesDeleted-ZIA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 One Zone-IA storage
<i>region</i> -C3DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 from Amazon EC2 within the same AWS Region
<i>region</i> -C3DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to Amazon EC2 within the same AWS Region

Usage Type	Units	Granularity	Description
<i>region</i> -CloudFront-In-Bytes	GB	Hourly	The amount of data transferred into an AWS Region from a CloudFront distribution
<i>region</i> -CloudFront-Out-Bytes	GB	Hourly	The amount of data transferred from an AWS Region to a CloudFront distribution
<i>region</i> -DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 from the internet
<i>region</i> -DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to the internet ¹
<i>region</i> -DataTransfer-Regional-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to AWS resources within the same AWS Region
<i>region</i> -EarlyDelete-ByteHrs	GB-Hours	Hourly	Prorated storage usage for objects deleted from, S3 Glacier Flexible Retrieval storage before the 90-day minimum commitment ended ²

Usage Type	Units	Granularity	Description
<i>region</i> -EarlyDelete-GDA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Glacier Deep Archive storage before the 180-day minimum commitment ended ²
<i>region</i> -EarlyDelete-GIR	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Glacier Instant Retrieval before the 90-day minimum commitment ended.
<i>region</i> -EarlyDelete-GIR-SmallObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 Glacier Instant Retrieval before the 90-day minimum commitment ended.
<i>region</i> -EarlyDelete-SIA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Standard-IA before the 30-day minimum commitment ended ³

Usage Type	Units	Granularity	Description
<i>region</i> -EarlyDelete-SIA-SmallObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 Standard-IA before the 30-day minimum commitment ended ³
<i>region</i> -EarlyDelete-ZIA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 One Zone-IA before the 30-day minimum commitment ended ³
<i>region</i> -EarlyDelete-ZIA-SmallObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 One Zone-IA before the 30-day minimum commitment ended ³
<i>region</i> -Expedited-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with Expedited S3 Glacier Flexible Retrieval requests
<i>region</i> -Inventory-Objects Listed	Objects	Hourly	The number of objects listed for an object group (objects are grouped by bucket or prefix) with an inventory list

Usage Type	Units	Granularity	Description
<i>region</i> -Monitoring-Automation-INT	Objects	Hourly	The number of unique objects monitored and auto-tiered in the S3 Intelligent-Tiering storage class
<i>region</i> -MRAP-Out-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint out of buckets in a Region (MRAP data routing pricing).
<i>region</i> -MRAP-In-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint out of buckets in a Region (MRAP data routing pricing).
<i>regiongroup1</i> - <i>regiongroup2</i> -MRAP-Out-Bytes	-	GB	Hourly The amount of data transferred through an S3 Multi-Region Access Points endpoint from a bucket in <i>regiongroup1</i> to a client in <i>regiongroup2</i> located outside of the AWS network.

Usage Type	Units	Granularity	Description
<i>region</i> group1- <i>region</i> group2-MRAP-In-Bytes -	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint to a bucket in <i>region</i> group1 from a client in <i>region</i> group2 located outside of the AWS network.
<i>region</i> -OverwriteBytes-Copy-GDA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Deep Archive storage
<i>region</i> -OverwriteBytes-Copy-GIR	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -OverwriteBytes-Copy-GLACIER	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Flexible Retrieval storage
<i>region</i> -OverwriteBytes-Copy-INT	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Copy-RRS	GB	Monthly	The amount of data overwritten by a CopyObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -OverwriteBytes-Copy-SIA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Standard-IA storage
<i>region</i> -OverwriteBytes-Copy-STANDARD	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Standard storage
<i>region</i> -OverwriteBytes-Copy-ZIA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 One Zone-IA storage
<i>region</i> -OverwriteBytes-Put-GDA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Deep Archive storage

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Put-GIR	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -OverwriteBytes-Put-GLACIER	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Flexible Retrieval storage
<i>region</i> -OverwriteBytes-Put-INT	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Intelligent-Tiering storage
<i>region</i> -OverwriteBytes-Put-RRS	GB	Monthly	The amount of data overwritten by a PutObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -OverwriteBytes-Put-SIA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Standard-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Put-STANDARD	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Standard storage
<i>region</i> -OverwriteBytes-Put-ZIA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 One Zone-IA storage
<i>region1</i> - <i>region2</i> -S3RTC-In-Bytes	GB	Monthly	The amount of data transferred for S3 Replication Time Control (S3 RTC) from <i>region2</i> to <i>region1</i>
<i>region1</i> - <i>region2</i> -S3RTC-Out-Bytes	GB	Monthly	The amount of data transferred for S3 Replication Time Control (S3 RTC) from <i>region1</i> to <i>region2</i>
<i>region</i> -Requests-GDA-Tier1	Count	Hourly	The number of PUT, COPY, POST, CreateMultipartUpload , UploadPart , or CompleteMultipartUpload requests on S3 Glacier Deep Archive objects ⁶

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-GDA-Tier2	Count	Hourly	The number of GET and HEAD requests on S3 Glacier Deep Archive objects
<i>region</i> -Requests-GDA-Tier3	Count	Hourly	The number of S3 Glacier Deep Archive standard restore requests
<i>region</i> -Requests-GDA-Tier5	Count	Hourly	The number of Bulk S3 Glacier Deep Archive restore requests
<i>region</i> -Requests-GIR-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Glacier Instant Retrieval objects.
<i>region</i> -Requests-GIR-Tier2	Count	Hourly	The number of GET and all other non-S3 Glacier Instant Retrieval-Tier1 requests on S3 Glacier Instant Retrieval objects.
<i>region</i> -Requests-GLACIER-Tier1	Count	Hourly	The number of PUT, COPY, POST, CreateMultipartUpload , UploadPart , or CompleteMultipartUpload requests on S3 Glacier Flexible Retrieval objects 6

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-GLACIER-Tier2	Count	Hourly	The number of GET and all other requests not listed on S3 Glacier Flexible Retrieval objects
<i>region</i> -Requests-INT-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Intelligent-Tiering objects
<i>region</i> -Requests-INT-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests for S3 Intelligent-Tiering objects
<i>region</i> -Requests-SIA-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Standard-IA objects
<i>region</i> -Requests-SIA-Tier2	Count	Hourly	The number of GET and all other non-S3 Glacier Instant Retrieval -Tier1 requests on S3 Standard-IA objects
<i>region</i> -Requests-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests for S3 Standard, RRS, and tags, plus LIST requests for all buckets and objects

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests
<i>region</i> -Requests-Tier3	Count	Hourly	The number of lifecycle requests to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive and standard S3 Glacier Flexible Retrieval restore requests
<i>region</i> -Requests-Tier4	Count	Hourly	The number of lifecycle transitions to S3 Glacier Instant Retrieval, S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage
<i>region</i> -Requests-Tier5	Count	Hourly	The number of Bulk S3 Glacier Flexible Retrieval restore requests
<i>region</i> -Requests-Tier6	Count	Hourly	The number of Expedited S3 Glacier Flexible Retrieval restore requests
<i>region</i> -Requests-XZ-Tier1	Count	Hourly	The number of PUT or COPY requests on S3 Express One Zone objects

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-XZ-Tier2	Count	Hourly	The number of GET and all other non-S3 Express One Zone-Tier1 requests on S3 Express One Zone objects
<i>region</i> -Requests-ZIA-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 One Zone-IA objects
<i>region</i> -Requests-ZIA-Tier2	Count	Hourly	The number of GET and all other non-S3 One Zone-IA-Tier1 requests on S3 One Zone-IA objects
<i>region</i> -Retrieval-GIR	GB	Hourly	The amount of data retrieved from S3 Glacier Instant Retrieval storage.
<i>region</i> -Retrieval-SIA	GB	Hourly	The amount of data retrieved from S3 Standard-IA storage
<i>region</i> -Retrieval-XZ	GB	Hourly	The portion of the data that exceeds 512 KB in a given retrieval request (PUT or COPY) with S3 Express One Zone storage
<i>region</i> -Retrieval-ZIA	GB	Hourly	The amount of data retrieved from S3 One Zone-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -S3G-DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 to restore objects from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage
<i>region</i> -S3G-DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to transition objects to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage
<i>region</i> -Select-Returned-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Standard storage
<i>region</i> -Select-Returned-GIR-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Glacier Instant Retrieval storage.
<i>region</i> -Select-Returned-INT-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Intelligent-Tiering storage
<i>region</i> -Select-Returned-SIA-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Standard-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -Select-Returned-ZIA-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 One Zone-IA storage
<i>region</i> -Select-Scanned-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Standard storage
<i>region</i> -Select-Scanned-GIR-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Glacier Instant Retrieval storage.
<i>region</i> -Select-Scanned-INT-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Intelligent-Tiering storage
<i>region</i> -Select-Scanned-SIA-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Standard-IA storage
<i>region</i> -Select-Scanned-ZIA-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 One Zone-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -Standard-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with standard S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive requests
<i>region</i> -StorageAnalytics-ObjCount	Objects	Hourly	The number of unique objects monitored in each Storage Class Analysis configuration.
<i>region</i> -StorageLens-ObjCount	Objects	Daily	The number of unique objects in each S3 Storage Lens dashboard that are tracked by S3 Storage Lens advanced metrics and recommendations.
<i>region</i> -StorageLensFreeTier-ObjCount	Objects	Daily	The number of unique objects in each S3 Storage Lens dashboard that are tracked by S3 Storage Lens usage metrics.
StorageObjectCount	Count	Daily	The number of objects stored within a given bucket
<i>region</i> -TagStorage-TagHrs	Tag-Hours	Daily	The total of tags on all objects in the bucket reported by hour

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in S3 Standard storage
<i>region</i> -TimedStorage-GDA-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in S3 Glacier Deep Archive storage
<i>region</i> -TimedStorage-GDA-Staging	GB-Hours	Daily	The number of GB-hours that data was stored in S3 Glacier Deep Archive staging storage
<i>region</i> -TimedStorage-GIR-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in S3 Glacier Instant Retrieval storage.
<i>region</i> -TimedStorage-GIR-SmObjects	GB-Hours	Daily	The number of GB-hours that small objects (smaller than 128 KB) were stored in S3 Glacier Instant Retrieval storage.
<i>region</i> -TimedStorage-GlacierByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in S3 Glacier Flexible Retrieval storage
<i>region</i> -TimedStorage-GlacierStaging	GB-Hours	Daily	The number of GB-hours that data was stored in S3 Glacier Flexible Retrieval staging storage

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-INT-FA-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in the Frequent Access tier of S3 Intelligent-Tiering storage ⁵
<i>region</i> -TimedStorage-INT-IA-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in the Infrequent Access tier of S3 Intelligent-Tiering storage

<i>region</i> -TimedStorage-INT-AIA-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in the Archive Instant Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-INT-DAA-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in the Deep Archive Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-RSS-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in Reduced Redundancy Storage (RRS) storage

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-SIA-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in S3 Standard-IA storage
<i>region</i> -TimedStorage-SIA-SmObjects	GB-Hours	Daily	The number of GB-hours that small objects (smaller than 128 KB) were stored in S3 Standard-IA storage ⁴
<i>region</i> -TimedStorage-XZ-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in S3 Express One Zone storage
<i>region</i> -TimedStorage-ZIA-ByteHrs	GB-Hours	Daily	The number of GB-hours that data was stored in S3 One Zone-IA storage
<i>region</i> -TimedStorage-ZIA-SmObjects	GB-Hours	Daily	The number of GB-hours that small objects (smaller than 128 KB) were stored in S3 One Zone-IA storage
<i>region</i> -Upload-XZ	GB	Hourly	The amount of data that exceeds 512 KB in a given upload request (PUT or COPY) with S3 Express One Zone

Notes

1. If you terminate a transfer before completion, the amount of data that is transferred might exceed the amount of data that your application receives. This discrepancy can occur because

- a transfer termination request cannot be executed instantaneously, and some amount of data might be in transit, pending execution of the termination request. This data in transit is billed as data transferred "out."
2. When objects that are archived to the S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage class are deleted, overwritten, or transitioned to a different storage class before the minimum storage commitment has passed, which is 90 days for S3 Glacier Instant Retrieval and S3 Glacier Flexible Retrieval, or 180 days for S3 Glacier Deep Archive, there is a prorated charge per gigabyte for the remaining days.
 3. For objects that are in S3 Standard-IA or S3 One Zone-IA storage, when they are deleted, overwritten, or transitioned to a different storage class before 30 days, there is a prorated charge per gigabyte for the remaining days.
 4. For small objects (smaller than 128 KB) that are in S3 Standard-IA or S3 One Zone-IA storage, when they are deleted, overwritten, or transitioned to a different storage class before 30 days, there is a prorated charge per gigabyte for the remaining days.
 5. There is no minimum billable object size for objects in the S3 Intelligent-Tiering storage class. Objects that are smaller than 128 KB are not monitored or eligible for auto-tiering. Smaller objects are always stored in the S3 Intelligent-Tiering Frequent Access tier.
 6. When you initiate a `CreateMultipartUpload`, `UploadPart`, or `UploadPartCopy` request to either the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, requests are billed at S3 Standard request rates until you complete the multipart upload. After the upload is completed, the single `CompleteMultipartUpload` request is billed at the PUT rate for the destination S3 Glacier storage. In-progress multipart upload parts for a PUT to the S3 Glacier Flexible Retrieval storage class are billed as S3 Glacier Flexible Retrieval Staging Storage at S3 Standard storage rates until the upload is completed. Similarly, in-progress multipart upload parts for a PUT to the S3 Glacier Deep Archive storage class are billed as S3 Glacier Deep Archive Staging Storage at S3 Standard storage rates until the upload is completed.
 7. S3 Express One Zone applies a flat per-request charge for request sizes up to 512 KB. An additional per GB charge is applied for PUT requests and GET requests for the portion of request greater than 512 KB.
 8. For information about supported features for S3 Express One Zone storage class, see [Amazon S3 features not supported by S3 Express One Zone](#).

Tracking Operations in Your Usage Reports

Operations describe the action taken on your AWS object or bucket by the specified usage type. Operations are indicated by self-explanatory codes, such as PutObject or ListBucket. To see which actions on your bucket generated a specific type of usage, use these codes. When you create a usage report, you can choose to include **All Operations**, or a specific operation, for example, GetObject, to report on.

Filtering and retrieving data using Amazon S3 Select

With Amazon S3 Select, you can use structured query language (SQL) statements to filter the contents of an Amazon S3 object and retrieve only the subset of data that you need. By using Amazon S3 Select to filter this data, you can reduce the amount of data that Amazon S3 transfers, which reduces the cost and latency to retrieve this data.

Amazon S3 Select works on objects stored in CSV, JSON, or Apache Parquet format. It also works with objects that are compressed with GZIP or BZIP2 (for CSV and JSON objects only), and server-side encrypted objects. You can specify the format of the results as either CSV or JSON, and you can determine how the records in the result are delimited.

You pass SQL expressions to Amazon S3 in the request. Amazon S3 Select supports a subset of SQL. For more information about the SQL elements that are supported by Amazon S3 Select, see [SQL reference for Amazon S3 Select](#).

You can perform SQL queries using AWS SDKs, the SelectObjectContent REST API operation, the AWS Command Line Interface (AWS CLI), or the Amazon S3 console. The Amazon S3 console limits the amount of data returned to 40 MB. To retrieve more data, use the AWS CLI or the API.

Requirements and limits

The following are requirements for using Amazon S3 Select:

- You must have `s3:GetObject` permission for the object you are querying.
- If the object you are querying is encrypted with server-side encryption with customer-provided keys (SSE-C), you must use `https`, and you must provide the encryption key in the request.

The following limits apply when using Amazon S3 Select:

- The maximum length of a SQL expression is 256 KB.
- The maximum length of a record in the input or result is 1 MB.
- Amazon S3 Select can only emit nested data by using the JSON output format.
- You cannot query objects in the S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or Reduced Redundancy Storage (RRS) storage classes. You also cannot query the objects in the S3 Intelligent-Tiering Archive Access tier or the S3 Intelligent-Tiering Deep Archive Access tier. For more information about storage classes, see [Using Amazon S3 storage classes](#).

Additional limitations apply when using Amazon S3 Select with Parquet objects:

- Amazon S3 Select supports only columnar compression using GZIP or Snappy. Amazon S3 Select doesn't support whole-object compression for Parquet objects.
- Amazon S3 Select doesn't support Parquet output. You must specify the output format as CSV or JSON.
- The maximum uncompressed row group size is 512 MB.
- You must use the data types that are specified in the object's schema.
- Selecting on a repeated field returns only the last value.

Constructing a request

When you construct a request, you provide details of the object that is being queried by using an `InputSerialization` object. You provide details of how the results are to be returned by using an `OutputSerialization` object. You also include the SQL expression that Amazon S3 uses to filter the request.

For more information about constructing an Amazon S3 Select request, see [SelectObjectContent](#) in the *Amazon Simple Storage Service API Reference*. You can also see one of the SDK code examples in the following sections.

Requests using scan ranges

With Amazon S3 Select, you can scan a subset of an object by specifying a range of bytes to query. This capability lets you parallelize scanning the whole object by splitting the work into separate Amazon S3 Select requests for a series of non-overlapping scan ranges.

Scan ranges don't need to be aligned with record boundaries. An Amazon S3 Select scan range request runs across the byte range that you specify. A record that starts within the specified scan range but extends beyond that scan range will be processed by the query. For example, the following shows an Amazon S3 object that contains a series of records in a line-delimited CSV format:

```
A,B  
C,D  
D,E  
E,F  
G,H  
I,J
```

Suppose that you're using the Amazon S3 Select ScanRange parameter and *Start at (Byte) 1* and *End at (Byte) 4*. So the scan range would start at ", " and scan until the end of the record starting at C. Your scan range request will return the result C, D because that is the end of the record.

Amazon S3 Select scan range requests support Parquet, CSV (without quoted delimiters), and JSON objects (in LINES mode only). CSV and JSON objects must be uncompressed. For line-based CSV and JSON objects, when a scan range is specified as part of the Amazon S3 Select request, all records that start within the scan range are processed. For Parquet objects, all of the row groups that start within the scan range requested are processed.

Amazon S3 Select scan range requests are available to use with the AWS CLI, Amazon S3 API, and AWS SDKs. You can use the ScanRange parameter in the Amazon S3 Select request for this feature. For more information, see [SelectObjectContent](#) in the *Amazon Simple Storage Service API Reference*.

Errors

Amazon S3 Select returns an error code and associated error message when an issue is encountered while attempting to run a query. For a list of error codes and descriptions, see the [List of SELECT Object Content Error Codes](#) section of the *Error Responses* page in the *Amazon Simple Storage Service API Reference*.

For more information about Amazon S3 Select, see the following topics.

Topics

- [Examples of using Amazon S3 Select on objects](#)
- [SQL reference for Amazon S3 Select](#)

Examples of using Amazon S3 Select on objects

You can use S3 Select with the Amazon S3 console, the REST API, and the AWS SDKs to select content from objects.

For more information about supported SQL functions for S3 Select, see [SQL functions](#).

Using the S3 console

To select content from an object in the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose the bucket that contains the object that you want to select content from, and then choose the name of the object.
4. Choose **Object actions**, and choose **Query with S3 Select**.
5. Configure **Input settings**, based on the format of your input data.
6. Configure **Output settings**, based on the format of the output that you want to receive.
7. To extract records from the chosen object, under **SQL query**, enter the SELECT SQL commands. For more information on how to write SQL commands, see [SQL reference for Amazon S3 Select](#).
8. After you enter SQL queries, choose **Run SQL query**. Then, under **Query results**, you can see the results of your SQL queries.

Using the REST API

You can use the AWS SDKs to select content from objects. However, if your application requires it, you can send REST requests directly. For more information about the request and response format, see [SelectObjectContent](#).

Using the AWS SDKs

You can use Amazon S3 Select to select the contents of an object by using the `selectObjectContent` method. If this method is successful, it returns the results of the SQL expression.

Java

The following Java code returns the value of the first column for each record that is stored in an object that contains data stored in CSV format. It also requests Progress and Stats messages to be returned. You must provide a valid bucket name and an object that contains data in CSV format.

For instructions on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

```

JavaScript

For a JavaScript example that uses the AWS SDK for JavaScript with the S3 SelectObjectContent API operation to select records from JSON and CSV files that are

stored in Amazon S3, see the blog post [Introducing support for Amazon S3 Select in the AWS SDK for JavaScript](#).

Python

For a Python example of using SQL queries to search through data that was loaded to Amazon S3 as a comma-separated value (CSV) file by using S3 Select, see the blog post [Querying data without servers or databases using Amazon S3 Select](#).

SQL reference for Amazon S3 Select

This reference contains a description of the structured query language (SQL) elements that are supported by Amazon S3 Select.

Topics

- [SELECT command](#)
- [Data types](#)
- [Operators](#)
- [Reserved keywords](#)
- [SQL functions](#)

SELECT command

Amazon S3 Select supports only the SELECT SQL command. The following ANSI standard clauses are supported for SELECT:

- SELECT list
- FROM clause
- WHERE clause
- LIMIT clause

 **Note**

Amazon S3 Select queries currently do not support subqueries or joins.

SELECT list

The SELECT list names the columns, functions, and expressions that you want the query to return. The list represents the output of the query.

```
SELECT *
SELECT projection1 AS column_alias_1, projection2 AS column_alias_2
```

The first form of SELECT with the * (asterisk) returns every row that passed the WHERE clause, as-is. The second form of SELECT creates a row with user-defined output scalar expressions *projection1* and *projection2* for each column.

FROM clause

Amazon S3 Select supports the following forms of the FROM clause:

```
FROM table_name
FROM table_name alias
FROM table_name AS alias
```

In each form of the FROM clause, *table_name* is the S3Object that's being queried. Users coming from traditional relational databases can think of this as a database schema that contains multiple views over a table.

Following standard SQL, the FROM clause creates rows that are filtered in the WHERE clause and projected in the SELECT list.

For JSON objects that are stored in Amazon S3 Select, you can also use the following forms of the FROM clause:

```
FROM S3Object[*].path
FROM S3Object[*].path alias
FROM S3Object[*].path AS alias
```

Using this form of the FROM clause, you can select from arrays or objects within a JSON object. You can specify path by using one of the following forms:

- By name (in an object): `.name` or `['name']`
- By index (in an array): `[index]`

- By wildcard character (in an object): `.*`
- By wildcard character (in an array): `[*]`

Note

- This form of the `FROM` clause works only with JSON objects.
- Wildcard characters always emit at least one record. If no record matches, then Amazon S3 Select emits the value `MISSING`. During output serialization (after the query finishes running), Amazon S3 Select replaces `MISSING` values with empty records.
- Aggregate functions (`AVG`, `COUNT`, `MAX`, `MIN`, and `SUM`) skip `MISSING` values.
- If you don't provide an alias when using a wildcard character, you can refer to the row by using the last element in the path. For example, you could select all prices from a list of books by using the query `SELECT price FROM S3Object[*].books[*].price`. If the path ends in a wildcard character instead of a name, then you can use the value `_1` to refer to the row. For example, instead of `SELECT price FROM S3Object[*].books[*].price`, you could use the query `SELECT _1.price FROM S3Object[*].books[*]`.
- Amazon S3 Select always treats a JSON document as an array of root-level values. Thus, even if the JSON object that you are querying has only one root element, the `FROM` clause must begin with `S3Object[*]`. However, for compatibility reasons, Amazon S3 Select allows you to omit the wildcard character if you don't include a path. Thus, the complete clause `FROM S3Object` is equivalent to `FROM S3Object[*] as S3Object`. If you include a path, you must also use the wildcard character. So, `FROM S3Object` and `FROM S3Object[*].path` are both valid clauses, but `FROM S3Object.path` is not.

Example

Examples:

Example #1

This example shows results when using the following dataset and query:

```
{ "Rules": [ {"id": "1"}, {"expr": "y > x"}, {"id": "2", "expr": "z = DEBUG"} ]}  
{ "created": "June 27", "modified": "July 6" }
```

```
SELECT id FROM S3Object[*].Rules[*].id
```

```
{"id":"1"}  
{}  
{"id":"2"}  
{}
```

Amazon S3 Select produces each result for the following reasons:

- {"id":"id-1"} – S3Object[0].Rules[0].id produced a match.
- {} – S3Object[0].Rules[1].id did not match a record, so Amazon S3 Select emitted MISSING, which was then changed to an empty record during output serialization and returned.
- {"id":"id-2"} – S3Object[0].Rules[2].id produced a match.
- {} – S3Object[1] did not match on Rules, so Amazon S3 Select emitted MISSING, which was then changed to an empty record during output serialization and returned.

If you don't want Amazon S3 Select to return empty records when it doesn't find a match, you can test for the value MISSING. The following query returns the same results as the previous query, but with the empty values omitted:

```
SELECT id FROM S3Object[*].Rules[*].id WHERE id IS NOT MISSING
```

```
{"id":"1"}  
{"id":"2"}
```

Example #2

This example shows results when using the following dataset and queries:

```
{ "created": "936864000", "dir_name": "important_docs", "files": [ { "name": "." },  
 { "name": ".." }, { "name": ".aws" }, { "name": "downloads" } ], "owner": "Amazon  
S3" }  
{ "created": "936864000", "dir_name": "other_docs", "files": [ { "name": "." },  
 { "name": ".." }, { "name": "my stuff" }, { "name": "backup" } ], "owner": "User" }
```

```
SELECT d.dir_name, d.files FROM S3Object[*] d
```

```
{"dir_name": "important_docs", "files": [{"name": "."}, {"name": ".."}, {"name": ".aws"}, {"name": "downloads"}]}  
{"dir_name": "other_docs", "files": [{"name": "."}, {"name": ".."}, {"name": "my stuff"}, {"name": "backup"}]}
```

```
SELECT _1.dir_name, _1.owner FROM S3Object[*]
```

```
{"dir_name": "important_docs", "owner": "Amazon S3"}  
{"dir_name": "other_docs", "owner": "User"}
```

WHERE clause

The WHERE clause follows this syntax:

```
WHERE condition
```

The WHERE clause filters rows based on the *condition*. A condition is an expression that has a Boolean result. Only rows for which the condition evaluates to TRUE are returned in the result.

LIMIT clause

The LIMIT clause follows this syntax:

```
LIMIT number
```

The LIMIT clause limits the number of records that you want the query to return based on *number*.

Attribute access

The SELECT and WHERE clauses can refer to record data by using one of the methods in the following sections, depending on whether the file that is being queried is in CSV or JSON format.

CSV

- **Column Numbers** – You can refer to the *Nth* column of a row with the column name *_N*, where *N* is the column position. The position count starts at 1. For example, the first column is named *_1* and the second column is named *_2*.

You can refer to a column as `_N` or `alias._N`. For example, `_2` and `myAlias._2` are both valid ways to refer to a column in the SELECT list and WHERE clause.

- **Column Headers** – For objects in CSV format that have a header row, the headers are available to the SELECT list and WHERE clause. In particular, as in traditional SQL, within SELECT and WHERE clause expressions, you can refer to the columns by `alias.column_name` or `column_name`.

JSON

- **Document** – You can access JSON document fields as `alias.name`. You can also access nested fields, for example, `alias.name1.name2.name3`.
- **List** – You can access elements in a JSON list by using zero-based indexes with the `[]` operator. For example, you can access the second element of a list as `alias[1]`. You can combine accessing list elements with fields, for example, `alias.name1.name2[1].name3`.
- **Examples:** Consider this JSON object as a sample dataset:

```
{"name": "Susan Smith",
"org": "engineering",
"projects":
[
    {"project_name": "project1", "completed": false},
    {"project_name": "project2", "completed": true}
]}
```

Example #1

The following query returns these results:

```
Select s.name from S3Object s
```

```
{"name": "Susan Smith"}
```

Example #2

The following query returns these results:

```
Select s.projects[0].project_name from S3object s
```

```
{"project_name": "project1"}
```

Case sensitivity of header and attribute names

With Amazon S3 Select, you can use double quotation marks to indicate that column headers (for CSV objects) and attributes (for JSON objects) are case sensitive. Without double quotation marks, object headers and attributes are case insensitive. An error is thrown in cases of ambiguity.

The following examples are either 1) Amazon S3 objects in CSV format with the specified column headers, and with `FileHeaderInfo` set to "Use" for the query request; or 2) Amazon S3 objects in JSON format with the specified attributes.

Example #1: The object being queried has the header or attribute NAME.

- The following expression successfully returns values from the object. Because there are no quotation marks, the query is case insensitive.

```
SELECT s.name from S3object s
```

- The following expression results in a 400 error `MissingHeaderName`. Because there are quotation marks, the query is case sensitive.

```
SELECT s."name" from S3object s
```

Example #2: The Amazon S3 object being queried has one header or attribute with NAME and another header or attribute with name.

- The following expression results in a 400 error `AmbiguousFieldName`. Because there are no quotation marks, the query is case insensitive, but there are two matches, so the error is thrown.

```
SELECT s.name from S3object s
```

- The following expression successfully returns values from the object. Because there are quotation marks, the query is case sensitive, so there is no ambiguity.

```
SELECT s."NAME" from S3Object s
```

Using reserved keywords as user-defined terms

Amazon S3 Select has a set of reserved keywords that are needed to run the SQL expressions used to query object content. Reserved keywords include function names, data types, operators, and so on. In some cases, user-defined terms, such as the column headers (for CSV files) or attributes (for JSON objects), might clash with a reserved keyword. When this happens, you must use double quotation marks to indicate that you are intentionally using a user-defined term that clashes with a reserved keyword. Otherwise a 400 parse error will result.

For the full list of reserved keywords, see [Reserved keywords](#).

The following example is either 1) an Amazon S3 object in CSV format with the specified column headers, with `FileInfo` set to "Use" for the query request, or 2) an Amazon S3 object in JSON format with the specified attributes.

Example: The object being queried has a header or attribute named `CAST`, which is a reserved keyword.

- The following expression successfully returns values from the object. Because quotation marks are used in the query, S3 Select uses the user-defined header or attribute.

```
SELECT s."CAST" from S3Object s
```

- The following expression results in a 400 parse error. Because no quotation marks are used in the query, `CAST` clashes with a reserved keyword.

```
SELECT s.CAST from S3Object s
```

Scalar expressions

Within the `WHERE` clause and the `SELECT` list, you can have SQL *scalar expressions*, which are expressions that return scalar values. They have the following form:

- **literal**

An SQL literal.

- ***column_reference***

A reference to a column in the form *column_name* or *alias.column_name*.

- ***unary_op expression***

In this case, *unary_op* is an SQL unary operator.

- ***expression binary_op expression***

In this case, *binary_op* is an SQL binary operator.

- ***func_name***

In this case, *func_name* is the name of the scalar function to invoke.

- ***expression* [NOT] BETWEEN *expression* AND *expression***

- ***expression* LIKE *expression* [ESCAPE *expression*]**

Data types

Amazon S3 Select supports several primitive data types.

Data type conversions

The general rule is to follow the CAST function if it's defined. If CAST is not defined, then all input data is treated as a string. In that case, you must cast your input data into the relevant data types when necessary.

For more information about the CAST function, see [CAST](#).

Supported data types

Amazon S3 Select supports the following set of primitive data types.

Name	Description	Examples
bool	A Boolean value, either TRUE or FALSE.	FALSE
int, integer	An 8-byte signed integer in the range -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807.	100000

Name	Description	Examples
string	A UTF8-encoded variable-length string. The default limit is 1 character. The maximum character limit is 2,147,483,647.	'xyz'
float	An 8-byte floating point number.	CAST(0.456 AS FLOAT)
decimal, numeric	A base-10 number, with a maximum precision of 38 (that is, the maximum number of significant digits), and with a scale within the range of -2 ³¹ to 2 ³¹ -1 (that is, the base-10 exponent).	123.456
<p>Note</p> <p>Amazon S3 Select ignores scale and precision when you provide both at the same time.</p>		
timestamp	<p>Timestamps represent a specific moment in time, always include a local offset, and are capable of arbitrary precision.</p> <p>In the text format, timestamps follow the W3C note on date and time formats, but they must end with the literal T if the timestamps are not at least whole-day precision. Fractional seconds are allowed, with at least one digit of precision, and an unlimited maximum. Local-time offsets can be represented as either hour:minute offsets from UTC, or as the literal Z to denote a local time of UTC. Local-time offsets are required on timestamps with time and are not allowed on date values.</p>	CAST('2007-04-05T14:30Z' AS TIMESTAMP)

Supported Parquet types

Amazon S3 Select supports the following Parquet types.

- DATE
- DECIMAL
- ENUM
- INT(8)
- INT(16)
- INT(32)
- INT(64)
- LIST

 **Note**

For LIST Parquet type output, Amazon S3 Select supports only JSON format. However, if the query limits the data to simple values, the LIST Parquet type can also be queried in CSV format.

- STRING
- TIMESTAMP supported precision (MILLIS/MICROS/NANOS)

 **Note**

Timestamps saved as an INT(96) are unsupported.

Because of the range of the INT(64) type, timestamps that are using the NANOS unit can represent only values between 1677-09-21 00:12:43 and 2262-04-11 23:47:16. Values outside of this range cannot be represented with the NANOS unit.

Mapping of Parquet types to supported data types in Amazon S3 Select

Parquet types	Supported data types
DATE	timestamp
DECIMAL	decimal, numeric

Parquet types	Supported data types
ENUM	string
INT(8)	int, integer
INT(16)	int, integer
INT(32)	int, integer
INT(64)	decimal, numeric
LIST	Each Parquet type in list is mapped to the corresponding data type.
STRING	string
TIMESTAMP	timestamp

Operators

Amazon S3 Select supports the following operators.

Logical operators

- AND
- NOT
- OR

Comparison operators

- <
- >
- <=
- >=

- =
- <>
- !=
- BETWEEN
- IN – For example: IN ('a', 'b', 'c')

Pattern-matching operators

- LIKE
- _ (Matches any character)
- % (Matches any sequence of characters)

Unitary operators

- IS NULL
- IS NOT NULL

Math operators

Addition, subtraction, multiplication, division, and modulo are supported, as follows:

- +
- -
- *
- /
- %

Operator precedence

The following table shows the operators' precedence in decreasing order.

Operator or element	Associativity	Required
-	right	unary minus
*, /, %	left	multiplication, division, modulo
+, -	left	addition, subtraction
IN		set membership
BETWEEN		range containment
LIKE		string pattern matching
<>		less than, greater than
=	right	equality, assignment
NOT	right	logical negation
AND	left	logical conjunction
OR	left	logical disjunction

Reserved keywords

The following is the list of reserved keywords for Amazon S3 Select. These keywords include function names, data types, operators, and so on, that are needed to run the SQL expressions that are used to query object content.

SQL functions

Amazon S3 Select supports the following SQL functions.

Topics

- [Aggregate functions](#)
- [Conditional functions](#)
- [Conversion functions](#)
- [Date functions](#)
- [String functions](#)

Aggregate functions

Amazon S3 Select supports the following aggregate functions.

Function	Argument type	Return type
AVG(<i>expressic</i> <i>n</i>)	INT, FLOAT, DECIMAL	DECIMAL for an INT argument, FLOAT for a floating-point argument; otherwise the same as the argument data type.
COUNT	-	INT
MAX(<i>expressic</i> <i>n</i>)	INT, DECIMAL	Same as the argument type.
MIN(<i>expressic</i> <i>n</i>)	INT, DECIMAL	Same as the argument type.
SUM(<i>expressic</i> <i>n</i>)	INT, FLOAT, DOUBLE, DECIMAL	INT for an INT argument, FLOAT for a floating-point argument; otherwise, the same as the argument data type.

SUM example

To aggregate the total object sizes of a folder in an [S3 Inventory report](#), use a SUM expression.

The following S3 Inventory report is a CSV file that's compressed with GZIP. There are three columns.

- The first column is the name of the S3 bucket (*DOC-EXAMPLE-BUCKET*) that the S3 Inventory report is for.
- The second column is the object key name that uniquely identifies the object in the bucket.

The *example-folder/* value in the first row is for the folder *example-folder*. In Amazon S3, when you create a folder in your bucket, S3 creates a 0-byte object with a key that's set to the folder name that you provided.

The *example-folder/object1* value in the second row is for the object *object1* in the folder *example-folder*.

The *example-folder/object2* value in the third row is for the object *object2* in the folder *example-folder*.

For more information about S3 folders, see [Organizing objects in the Amazon S3 console by using folders](#).

- The third column is the object size in bytes.

```
"DOC-EXAMPLE-BUCKET","example-folder/","0"
"DOC-EXAMPLE-BUCKET","example-folder/object1","2011267"
"DOC-EXAMPLE-BUCKET","example-folder/object2","1570024"
```

To use a SUM expression to calculate the total size of the folder *example-folder*, run the SQL query with Amazon S3 Select.

```
SELECT SUM(CAST(_3 as INT)) FROM s3object s WHERE _2 LIKE '%example-folder/%' AND _2 != 'example-folder/' ;
```

Query Result:

```
3581291
```

Conditional functions

Amazon S3 Select supports the following conditional functions.

Topics

- [CASE](#)
- [COALESCE](#)
- [NULLIF](#)

CASE

The CASE expression is a conditional expression, similar to `if/then/else` statements found in other languages. CASE is used to specify a result when there are multiple conditions. There are two types of CASE expressions: simple and searched.

In simple CASE expressions, an expression is compared with a value. When a match is found, the specified action in the THEN clause is applied. If no match is found, the action in the ELSE clause is applied.

In searched CASE expressions, each CASE is evaluated based on a Boolean expression, and the CASE statement returns the first matching CASE. If no matching CASE is found among the WHEN clauses, the action in the ELSE clause is returned.

Syntax

Note

Currently, Amazon S3 Select doesn't support ORDER BY or queries that contain new lines. Make sure that you use queries with no line breaks.

The following is a simple CASE statement that's used to match conditions:

```
CASE expression WHEN value THEN result [WHEN...] [ELSE result] END
```

The following is a searched CASE statement that's used to evaluate each condition:

```
CASE WHEN boolean condition THEN result [WHEN ...] [ELSE result] END
```

Examples

Note

If you use the Amazon S3 console to run the following examples and your CSV file contains a header row, choose **Exclude the first line of CSV data**.

Example 1: Use a simple CASE expression to replace New York City with Big Apple in a query. Replace all other city names with other.

```
SELECT venuecity, CASE venuecity WHEN 'New York City' THEN 'Big Apple' ELSE 'other' END  
FROM S3Object;
```

Query result:

venuecity	case
Los Angeles	other
New York City	Big Apple
San Francisco	other
Baltimore	other
...	

Example 2: Use a searched CASE expression to assign group numbers based on the pricepaid value for individual ticket sales:

```
SELECT pricepaid, CASE WHEN CAST(pricepaid as FLOAT) < 10000 THEN 'group 1' WHEN  
CAST(pricepaid as FLOAT) > 10000 THEN 'group 2' ELSE 'group 3' END FROM S3Object;
```

Query result:

pricepaid	case
12624.00	group 2
10000.00	group 3
10000.00	group 3
9996.00	group 1
9988.00	group 1
...	

COALESCE

COALESCE evaluates the arguments in order and returns the first non-unknown value, that is, the first non-null or non-missing value. This function does not propagate null and missing values.

Syntax

```
COALESCE ( expression, expression, ... )
```

Parameters

expression

The target expression that the function operates on.

Examples

```
COALESCE(1)          -- 1
COALESCE(null)        -- null
COALESCE(null, null)  -- null
COALESCE(missing)     -- null
COALESCE(missing, missing) -- null
COALESCE(1, null)      -- 1
COALESCE(null, null, 1) -- 1
COALESCE(null, 'string') -- 'string'
COALESCE(missing, 1)    -- 1
```

NULIF

Given two expressions, NULIF returns NULL if the two expressions evaluate to the same value; otherwise, NULIF returns the result of evaluating the first expression.

Syntax

```
NULIF ( expression1, expression2 )
```

Parameters

expression1, *expression2*

The target expressions that the function operates on.

Examples

```
NULLIF(1, 1)          -- null
NULLIF(1, 2)          -- 1
NULLIF(1.0, 1)        -- null
NULLIF(1, '1')        -- 1
NULLIF([1], [1])      -- null
NULLIF(1, NULL)       -- 1
NULLIF(NULL, 1)       -- null
NULLIF(null, null)    -- null
NULLIF(missing, null) -- null
NULLIF(missing, missing) -- null
```

Conversion functions

Amazon S3 Select supports the following conversion function.

Topics

- [CAST](#)

CAST

The CAST function converts an entity, such as an expression that evaluates to a single value, from one type to another.

Syntax

```
CAST ( expression AS data_type )
```

Parameters

expression

A combination of one or more values, operators, and SQL functions that evaluate to a value.

data_type

The target data type, such as INT, to cast the expression to. For a list of supported data types, see [Data types](#).

Examples

```
CAST('2007-04-05T14:30Z' AS TIMESTAMP)
CAST(0.456 AS FLOAT)
```

Date functions

Amazon S3 Select supports the following date functions.

Topics

- [DATE_ADD](#)
- [DATE_DIFF](#)
- [EXTRACT](#)
- [TO_STRING](#)
- [TO_TIMESTAMP](#)
- [UTCNOW](#)

DATE_ADD

Given a date part, a quantity, and a timestamp, DATE_ADD returns an updated timestamp by altering the date part by the quantity.

Syntax

```
DATE_ADD( date_part, quantity, timestamp )
```

Parameters

date_part

Specifies which part of the date to modify. This can be one of the following:

- year
- month
- day
- hour
- minute

- second

quantity

The value to apply to the updated timestamp. Positive values for *quantity* add to the timestamp's date_part, and negative values subtract.

timestamp

The target timestamp that the function operates on.

Examples

```
DATE_ADD(year, 5, `2010-01-01T`)  
2015-01-01T) -- 2015-01-01 (equivalent to  
DATE_ADD(month, 1, `2010T`)  
as necessary) -- 2010-02T (result will add precision  
DATE_ADD(month, 13, `2010T`)  
-- 2011-02T  
DATE_ADD(day, -1, `2017-01-10T`)  
2017-01-09T) -- 2017-01-09 (equivalent to  
DATE_ADD(hour, 1, `2017T`)  
-- 2017-01-01T01:00-00:00  
DATE_ADD(hour, 1, `2017-01-02T03:04Z`)  
-- 2017-01-02T04:04Z  
DATE_ADD(minute, 1, `2017-01-02T03:04:05.006Z`)  
-- 2017-01-02T03:05:05.006Z  
DATE_ADD(second, 1, `2017-01-02T03:04:05.006Z`)  
-- 2017-01-02T03:04:06.006Z
```

DATE_DIFF

Given a date part and two valid timestamps, DATE_DIFF returns the difference in date parts. The return value is a negative integer when the *date_part* value of *timestamp1* is greater than the *date_part* value of *timestamp2*. The return value is a positive integer when the *date_part* value of *timestamp1* is less than the *date_part* value of *timestamp2*.

Syntax

```
DATE_DIFF( date_part, timestamp1, timestamp2 )
```

Parameters

date_part

Specifies which part of the timestamps to compare. For the definition of *date_part*, see [DATE_ADD](#).

timestamp1

The first timestamp to compare.

timestamp2

The second timestamp to compare.

Examples

```
DATE_DIFF(year, `2010-01-01T`, `2011-01-01T`)          -- 1
DATE_DIFF(year, `2010T`, `2010-05T`)                  -- 4 (2010T is equivalent to
2010-01-01T00:00:00.000Z)
DATE_DIFF(month, `2010T`, `2011T`)                   -- 12
DATE_DIFF(month, `2011T`, `2010T`)                   -- -12
DATE_DIFF(day, `2010-01-01T23:00`, `2010-01-02T01:00`) -- 0 (need to be at least 24h
apart to be 1 day apart)
```

EXTRACT

Given a date part and a timestamp, EXTRACT returns the timestamp's date part value.

Syntax

```
EXTRACT( date_part FROM timestamp )
```

Parameters

date_part

Specifies which part of the timestamps to extract. This can be one of the following:

- YEAR
- MONTH
- DAY
- HOUR
- MINUTE
- SECOND
- TIMEZONE_HOUR
- TIMEZONE_MINUTE

timestamp

The target timestamp that the function operates on.

Examples

```
EXTRACT(YEAR FROM `2010-01-01T` ) -- 2010  
EXTRACT(MONTH FROM `2010T` ) -- 1 (equivalent to  
2010-01-01T00:00:00.000Z)  
EXTRACT(MONTH FROM `2010-10T` ) -- 10  
EXTRACT(HOUR FROM `2017-01-02T03:04:05+07:08` ) -- 3  
EXTRACT(MINUTE FROM `2017-01-02T03:04:05+07:08` ) -- 4  
EXTRACT(TIMEZONE_HOUR FROM `2017-01-02T03:04:05+07:08` ) -- 7  
EXTRACT(TIMEZONE_MINUTE FROM `2017-01-02T03:04:05+07:08` ) -- 8
```

TO_STRING

Given a timestamp and a format pattern, TO_STRING returns a string representation of the timestamp in the given format.

Syntax

```
TO_STRING ( timestamp time_format_pattern )
```

Parameters

timestamp

The target timestamp that the function operates on.

time_format_pattern

A string that has the following special character interpretations:

Format	Example	Description
yy	69	2-digit year
y	1969	4-digit year
yyyy	1969	Zero-padded 4-digit year

Format	Example	Description
M	1	Month of year
MM	01	Zero-padded month of year
MMM	Jan	Abbreviated month year name
MMMM	January	Full month of year name
MMMMM	J	Month of year first letter (NOTE: This format is not valid for use with the TO_TIMESTAMP function.)
d	2	Day of month (1-31)
dd	02	Zero-padded day of month (01-31)
a	AM	AM or PM of day
h	3	Hour of day (1-12)

Format	Example	Description
hh	03	Zero-padded hour of day (0 1-12)
H	3	Hour of day (0-23)
HH	03	Zero-padded hour of day (0 0-23)
m	4	Minute of hour (0-59)
mm	04	Zero-padded minute of hour (00-59)
s	5	Second of minute (0-59)
ss	05	Zero-padded second of minute (00-59)
S	0	Fraction of a second (precision: 0.1, range: 0.0-0.9)
SS	6	Fraction of a second (precision: 0.01, range: 0.0-0.99)

Format	Example	Description
SSS	60	Fraction of a second (precision: 0.001, range: 0.0-0.999)
...
SSSSSSSS	60000000	Fraction of a second (maximum precision: 1 nanosecond, range: 0.0-0.999999999)
n	60000000	Nano of a second
X	+07 or Z	Offset in hours, or Z if the offset is 0
XX or XXXX	+0700 or Z	Offset in hours and minutes, or Z if the offset is 0
XXX or XXXXX	+07:00 or Z	Offset in hours and minutes, or Z if the offset is 0

Format	Example	Description
x	7	Offset in hours
xx or xxxx	700	Offset in hours and minutes
xxx or xxxxx	+07:00	Offset in hours and minutes

Examples

```

TO_STRING(`1969-07-20T20:18Z`, 'MMMM d, y')          -- "July 20, 1969"
TO_STRING(`1969-07-20T20:18Z`, 'MMM d, yyyy')        -- "Jul 20, 1969"
TO_STRING(`1969-07-20T20:18Z`, 'M-d-yy')              -- "7-20-69"
TO_STRING(`1969-07-20T20:18Z`, 'MM-d-y')              -- "07-20-1969"
TO_STRING(`1969-07-20T20:18Z`, 'MMMM d, y h:m a')    -- "July 20, 1969 8:18 PM"
TO_STRING(`1969-07-20T20:18Z`, 'y-MM-dd''T''H:m:ssX') -- "1969-07-20T20:18:00Z"
TO_STRING(`1969-07-20T20:18+08:00Z`, 'y-MM-dd''T''H:m:ssX') -- "1969-07-20T20:18:00Z"
TO_STRING(`1969-07-20T20:18+08:00`, 'y-MM-dd''T''H:m:ssXXXX') -- "1969-07-20T20:18:00+0800"
TO_STRING(`1969-07-20T20:18+08:00`, 'y-MM-dd''T''H:m:ssXXXX') -- "1969-07-20T20:18:00+08:00"

```

TO_TIMESTAMP

Given a string, TO_TIMESTAMP converts it to a timestamp. TO_TIMESTAMP is the inverse operation of TO_STRING.

Syntax

```
TO_TIMESTAMP ( string )
```

Parameters

string

The target string that the function operates on.

Examples

```
TO_TIMESTAMP('2007T')          -- `2007T`  
TO_TIMESTAMP('2007-02-23T12:14:33.079-08:00') -- `2007-02-23T12:14:33.079-08:00`
```

UTCNOW

UTCNOW returns the current time in UTC as a timestamp.

Syntax

```
UTCNOW()
```

Parameters

UTCNOW takes no parameters.

Examples

```
UTCNOW() -- 2017-10-13T16:02:11.123Z
```

String functions

Amazon S3 Select supports the following string functions.

Topics

- [CHAR_LENGTH, CHARACTER_LENGTH](#)
- [LOWER](#)
- [SUBSTRING](#)
- [TRIM](#)
- [UPPER](#)

CHAR_LENGTH, CHARACTER_LENGTH

CHAR_LENGTH (or CHARACTER_LENGTH) counts the number of characters in the specified string.

Note

CHAR_LENGTH and CHARACTER_LENGTH are synonyms.

Syntax

```
CHAR_LENGTH ( string )
```

Parameters

string

The target string that the function operates on.

Examples

```
CHAR_LENGTH('')          -- 0
CHAR_LENGTH('abcdefg')   -- 7
```

LOWER

Given a string, LOWER converts all uppercase characters to lowercase characters. Any non-upercased characters remain unchanged.

Syntax

```
LOWER ( string )
```

Parameters

string

The target string that the function operates on.

Examples

```
LOWER('AbCdEfG!@#$') -- 'abcdefg!@#$'
```

SUBSTRING

Given a string, a start index, and optionally a length, SUBSTRING returns the substring from the start index up to the end of the string, or up to the length provided.

Note

The first character of the input string has an index position of 1.

- If `start` is < 1, with no length specified, then the index position is set to 1.
- If `start` is < 1, with a length specified, then the index position is set to `start` + `length` - 1.
- If `start` + `length` - 1 < 0, then an empty string is returned.
- If `start` + `length` - 1 >= 0, then the substring starting at index position 1 with the length `start` + `length` - 1 is returned.

Syntax

```
SUBSTRING( string FROM start [ FOR length ] )
```

Parameters

string

The target string that the function operates on.

start

The start position of the string.

length

The length of the substring to return. If not present, proceed to the end of the string.

Examples

```
SUBSTRING("123456789", 0)      -- "123456789"  
SUBSTRING("123456789", 1)      -- "123456789"  
SUBSTRING("123456789", 2)      -- "23456789"  
SUBSTRING("123456789", -4)     -- "123456789"  
SUBSTRING("123456789", 0, 999)  -- "123456789"  
SUBSTRING("123456789", 1, 5)    -- "12345"
```

TRIM

Trims leading or trailing characters from a string. The default character to remove is a space (' ').

Syntax

```
TRIM ( [[LEADING | TRAILING | BOTH remove_chars] FROM] string )
```

Parameters

string

The target string that the function operates on.

LEADING | TRAILING | BOTH

This parameter indicates whether to trim leading or trailing characters, or both leading and trailing characters.

remove_chars

The set of characters to remove. *remove_chars* can be a string with a length > 1. This function returns the string with any character from *remove_chars* found at the beginning or end of the string that was removed.

Examples

```
TRIM('      foobar      ')          -- 'foobar'  
TRIM('      \tfoobar\t      ')       -- '\tfoobar\t'  
TRIM(LEADING FROM '      foobar      ') -- 'foobar      '  
TRIM(TRAILING FROM '      foobar      ') -- '      foobar'  
TRIM(BOTH FROM '      foobar      ')  -- 'foobar'  
TRIM(BOTH '12' FROM '1112211foobar2221122') -- 'foobar'
```

UPPER

Given a string, UPPER converts all lowercase characters to uppercase characters. Any non-lowercased characters remain unchanged.

Syntax

```
UPPER ( string )
```

Parameters

string

The target string that the function operates on.

Examples

```
UPPER('AbCdEfG!@#$') -- 'ABCDEFG!@#$'
```

Performing large-scale batch operations on Amazon S3 objects

You can use S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. S3 Batch Operations can perform a single operation on lists of Amazon S3 objects that you specify. A single job can perform a specified operation on billions of objects containing exabytes of data. Amazon S3 tracks progress, sends notifications, and stores a detailed completion report of all actions, providing a fully managed, auditable, and serverless experience. You can use S3 Batch Operations through the AWS Management Console, AWS CLI, Amazon SDKs, or REST API.

Use S3 Batch Operations to copy objects and set object tags or access control lists (ACLs). You can also initiate object restores from S3 Glacier Flexible Retrieval or invoke an AWS Lambda function to perform custom actions using your objects. You can perform these operations on a custom list of objects, or you can use an Amazon S3 Inventory report to easily generate lists of objects. Amazon S3 Batch Operations use the same Amazon S3 APIs that you already use with Amazon S3, so you'll find the interface familiar.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [What is S3 Express One Zone?](#) and [Directory buckets](#). For more

information about using Batch Operations with S3 Express One Zone and directory buckets, see [Using Batch Operations with S3 Express One Zone](#).

S3 Batch Operations basics

You can use S3 Batch Operations to perform large-scale batch operations on Amazon S3 objects. S3 Batch Operations can run a single operation or action on lists of Amazon S3 objects that you specify.

Terminology

This section uses the terms *jobs*, *operations*, and *tasks*, which are defined as follows:

Job

A job is the basic unit of work for S3 Batch Operations. A job contains all of the information necessary to run the specified operation on the objects listed in the manifest. After you provide this information and request that the job begin, the job performs the operation for each object in the manifest.

Operation

The operation is the type of API [action](#), such as copying objects, that you want the Batch Operations job to run. Each job performs a single type of operation across all objects that are specified in the manifest.

Task

A task is the unit of execution for a job. A task represents a single call to an Amazon S3 or AWS Lambda API operation to perform the job's operation on a single object. Over the course of a job's lifetime, S3 Batch Operations create one task for each object specified in the manifest.

How an S3 Batch Operations job works

A job is the basic unit of work for S3 Batch Operations. A job contains all of the information necessary to run the specified operation on a list of objects. To create a job, you give S3 Batch Operations a list of objects and specify the action to perform on those objects.

For information about the operations that S3 Batch Operations supports, see [Operations supported by S3 Batch Operations](#).

A batch job performs a specified operation on every object that is included in its *manifest*. A manifest lists the objects that you want a batch job to process and it is stored as an object in a bucket. You can use a comma-separated values (CSV)-formatted [Amazon S3 Inventory](#) report as a manifest, which makes it easy to create large lists of objects located in a bucket. You can also specify a manifest in a simple CSV format that enables you to perform batch operations on a customized list of objects contained within a single bucket.

After you create a job, Amazon S3 processes the list of objects in the manifest and runs the specified operation against each object. While a job is running, you can monitor its progress programmatically or through the Amazon S3 console. You can also configure a job to generate a completion report when it finishes. The completion report describes the results of each task that was performed by the job. For more information about monitoring jobs, see [Managing S3 Batch Operations jobs](#).

S3 Batch Operations tutorial

The following tutorial presents complete end-to-end procedures for some Batch Operations tasks.

- [Tutorial: Batch-transcoding videos with S3 Batch Operations, AWS Lambda, and AWS Elemental MediaConvert](#)

Granting permissions for Amazon S3 Batch Operations

Before creating and running S3 Batch Operations jobs, you must grant required permissions. To create an Amazon S3 Batch Operations job, the `s3:CreateJob` user permission is required. The same entity that creates the job must also have the `iam:PassRole` permission to pass the AWS Identity and Access Management (IAM) role that is specified for the job to Batch Operations.

For general information about specifying IAM resources, see [IAM JSON policy, Resource elements](#) in the *IAM User Guide*. The following sections provide information about creating an IAM role and attaching policies.

Topics

- [Creating an S3 Batch Operations IAM role](#)
- [Attaching permissions policies](#)

Creating an S3 Batch Operations IAM role

Amazon S3 must have permissions to perform S3 Batch Operations on your behalf. You grant these permissions through an AWS Identity and Access Management (IAM) role. This section provides examples of the trust and permissions policies you use when creating an IAM role. For more information, see [IAM roles in the IAM User Guide](#). For examples, see [Controlling permissions for S3 Batch Operations using job tags](#) and [Copying objects using S3 Batch Operations](#).

In your IAM policies, you can also use condition keys to filter access permissions for S3 Batch Operations jobs. For more information and a complete list of Amazon S3 specific condition keys, see [Actions, resources, and condition keys for Amazon S3](#).

Trust policy

To allow the S3 Batch Operations service principal to assume the IAM role, attach the following trust policy to the role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "batchoperations.s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

Attaching permissions policies

Depending on the type of operations, you can attach one of the following policies.

Before you configure permissions, note the following:

- Regardless of the operation, Amazon S3 needs permissions to read your manifest object from your S3 bucket and optionally write a report to your bucket. Therefore, all of the following policies include these permissions.
- For Amazon S3 Inventory report manifests, S3 Batch Operations requires permission to read the manifest.json object and all associated CSV data files.

- Version-specific permissions such as `s3:GetObjectVersion` are only required when you are specifying the version ID of the objects.
- If you are running S3 Batch Operations on encrypted objects, the IAM role must also have access to the AWS KMS keys used to encrypt them.
- If you submit an inventory report manifest encrypted with AWS KMS, your IAM policy must include the permissions `"kms:Decrypt"` and `"kms:GenerateDataKey"` for the `manifest.json` object and all associated CSV data files.

Copy objects: PutObject

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "s3:PutObject",  
                "s3:PutObjectAcl",  
                "s3:PutObjectTagging"  
            ],  
            "Effect": "Allow",  
            "Resource": "arn:aws:s3:::DestinationBucket/*"  
        },  
        {  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectAcl",  
                "s3:GetObjectTagging",  
                "s3>ListBucket"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::SourceBucket",  
                "arn:aws:s3:::SourceBucket/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion"  
            ],  
            "Resource": "ObjectArn"  
        }  
    ]  
}
```

```
        "Resource": [
            "arn:aws:s3:::ManifestBucket/*"
        ],
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:PutObject"
        ],
        "Resource": [
            "arn:aws:s3:::ReportBucket/*"
        ]
    }
]
```

Replace object tagging: PutObjectTagging

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObjectTagging",
                "s3:PutObjectVersionTagging"
            ],
            "Resource": "arn:aws:s3:::TargetResource/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Resource": [
                "arn:aws:s3:::ManifestBucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ]
        }
    ]
}
```

```
],
"Resource": [
    "arn:aws:s3:::ReportBucket/*"
]
}
]
}
```

Delete object tagging: DeleteObjectTagging

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:DeleteObjectTagging",
                "s3:DeleteObjectVersionTagging"
            ],
            "Resource": [
                "arn:aws:s3:::TargetResource/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Resource": [
                "arn:aws:s3:::ManifestBucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::ReportBucket/*"
            ]
        }
    ]
}
```

{

Replace access control list: PutObjectAcl

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObjectAcl",  
                "s3:PutObjectVersionAcl"  
            ],  
            "Resource": "arn:aws:s3:::TargetResource/*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion"  
            ],  
            "Resource": [  
                "arn:aws:s3:::ManifestBucket/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::ReportBucket/*"  
            ]  
        }  
    ]  
}
```

Restore objects: RestoreObject

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {
```

```
"Effect": "Allow",
"Action": [
    "s3:RestoreObject"
],
"Resource": "arn:aws:s3:::TargetResource/*"
},
{
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:GetObjectVersion"
    ],
    "Resource": [
        "arn:aws:s3:::ManifestBucket/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:PutObject"
    ],
    "Resource": [
        "arn:aws:s3:::ReportBucket/*"
    ]
}
]
```

Apply Object Lock retention: PutObjectRetention

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:GetBucketObjectLockConfiguration",
            "Resource": [
                "arn:aws:s3:::TargetResource"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [

```

```
        "s3:PutObjectRetention",
        "s3:BypassGovernanceRetention"
    ],
    "Resource": [
        "arn:aws:s3:::TargetResource/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:GetObjectVersion"
    ],
    "Resource": [
        "arn:aws:s3:::ManifestBucket/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:PutObject"
    ],
    "Resource": [
        "arn:aws:s3:::ReportBucket/*"
    ]
}
]
}
```

Apply Object Lock legal hold: PutObjectLegalHold

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:GetBucketObjectLockConfiguration",
            "Resource": [
                "arn:aws:s3:::TargetResource"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "s3:PutObjectLegalHold"
        }
    ]
}
```

```
        "Action": "s3:PutObjectLegalHold",
        "Resource": [
            "arn:aws:s3:::TargetResource/*"
        ],
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:GetObject",
            "s3:GetObjectVersion"
        ],
        "Resource": [
            "arn:aws:s3:::ManifestBucket/*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:PutObject"
        ],
        "Resource": [
            "arn:aws:s3:::ReportBucket/*"
        ]
    }
]
}
```

Replicate existing objects: InitiateReplication with a S3 generated manifest

Use this policy if using and storing a S3 generated manifest. For more information about using Batch Operations for replicate existing objects see, [Replicating existing objects with S3 Batch Replication](#).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "s3:InitiateReplication"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::*** replication source bucket ***/*"
            ]
        }
    ]
}
```

```
        ],
    },
{
    "Action": [
        "s3:GetReplicationConfiguration",
        "s3:PutInventoryConfiguration"
    ],
    "Effect": "Allow",
    "Resource": [
        "arn:aws:s3:::*** replication source bucket ***"
    ]
},

    "Action": [
        "s3:GetObject",
        "s3:GetObjectVersion"
    ],
    "Effect": "Allow",
    "Resource": [
        "arn:aws:s3:::*** manifest bucket ***/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:PutObject"
    ],
    "Resource": [
        "arn:aws:s3:::*** completion report bucket ****/*",
        "arn:aws:s3:::*** manifest bucket ****/*"
    ]
}
]
}
```

Replicate existing objects: InitiateReplication with a user manifest

Use this policy if using a user supplied manifest. For more information about using Batch Operations for replicate existing objects see, [Replicating existing objects with S3 Batch Replication](#).

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
{  
    "Action": [  
        "s3:InitiateReplication"  
    ],  
    "Effect": "Allow",  
    "Resource": [  
        "arn:aws:s3:::*** replication source bucket ***/*"  
    ]  
},  
{  
    "Action": [  
        "s3:GetObject",  
        "s3:GetObjectVersion"  

```

Creating an S3 Batch Operations job

With Amazon S3 Batch Operations, you can perform large-scale batch operations on a list of specific Amazon S3 objects. This section describes the information that you need to create an S3 Batch Operations job and the results of a `CreateJob` request. It also provides instructions for creating a Batch Operations job by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

When you create an S3 Batch Operations job, you can request a completion report for all tasks or only for failed tasks. As long as at least one task has been invoked successfully, S3 Batch

Operations generates a report for jobs that have been completed, have failed, or have been canceled. For more information, see [Examples: S3 Batch Operations completion reports](#).

Topics

- [Batch Operations job request elements](#)
- [Specifying a manifest](#)

Batch Operations job request elements

To create an S3 Batch Operations job, you must provide the following information:

Operation

Specify the operation that you want S3 Batch Operations to run against the objects in the manifest. Each operation type accepts parameters that are specific to that operation. With Batch Operations, you can perform an operation in bulk, with the same results as if you performed that operation one-by-one on each object.

Manifest

The *manifest* is a list of all of the objects that you want S3 Batch Operations to run the specified operation on. You can use the following methods to specify a manifest for a Batch Operations job:

- Manually create your own customized, CSV-formatted object list.
- Choose an existing CSV-formatted [Amazon S3 Inventory](#) report.
- Direct Batch Operations to generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for batch replication jobs that you create in the Amazon S3 console, or for any job type that you create by using the AWS CLI, AWS SDKs, or Amazon S3 REST API.

Note

- Regardless of how you specify your manifest, the list itself must be stored in a general purpose bucket. Batch Operations can't import existing manifests from, or save generated manifests to directory buckets. Objects described within the manifest, however, can be stored in directory buckets. For more information, see [Directory buckets](#).

- If the objects in your manifest are in a versioned bucket, specifying the version IDs for the objects directs Batch Operations to perform the operation on a specific version. If no version IDs are specified, Batch Operations performs the operation on the latest version of the objects. If your manifest includes a version ID field, you must provide a version ID for all objects in the manifest.

For more information, see [Specifying a manifest](#).

Priority

Use job priorities to indicate the relative priority of this job to others running in your account. A higher number indicates higher priority.

Job priorities only have meaning relative to the priorities that are set for other jobs in the same account and Region. You can choose whatever numbering system works for you. For example, you might want to assign all **Restore** (RestoreObject) jobs a priority of 1, all **Copy** (CopyObject) jobs a priority of 2, and all **Replace access control lists (ACLs)** (PutObjectAcl) jobs a priority of 3.

S3 Batch Operations prioritizes jobs according to priority numbers, but strict ordering isn't guaranteed. Therefore, don't use job priorities to ensure that any one job starts or finishes before any other job. If you must ensure strict ordering, wait until one job has finished before starting the next.

RoleArn

Specify an AWS Identity and Access Management (IAM) role to run the job. The IAM role that you use must have sufficient permissions to perform the operation that is specified in the job. For example, to run a CopyObject job, the IAM role must have the s3:GetObject permission for the source bucket and the s3:PutObject permission for the destination bucket. The role also needs permissions to read the manifest and write the job-completion report.

For more information about IAM roles, see [IAM roles in the IAM User Guide](#).

For more information about Amazon S3 permissions, see [Amazon S3 actions](#).

Note

Batch Operations jobs that perform actions on directory buckets require specific permissions. For more information, see [AWS Identity and Access Management \(IAM\) for S3 Express One Zone](#).

Report

Specify whether you want S3 Batch Operations to generate a completion report. If you request a job-completion report, you must also provide the parameters for the report in this element. The necessary information includes:

- The bucket where you want to store the report

Note

The report must be stored in a general purpose bucket. Batch Operations can't save reports to directory buckets. For more information, see [Directory buckets](#).

- The format of the report
- Whether you want the report to include the details of all tasks or only failed tasks
- An optional prefix string

Tags (optional)

You can label and control access to your S3 Batch Operations jobs by adding *tags*. You can use tags to identify who is responsible for a Batch Operations job, or to control how users interact with Batch Operations jobs. The presence of job tags can grant or limit a user's ability to cancel a job, activate a job in the confirmation state, or change a job's priority level. For example, you could grant a user permission to invoke the CreateJob operation, provided that the job is created with the tag "Department=Finance".

You can create jobs with tags attached to them, and you can add tags to jobs after you create them.

For more information, see [the section called "Using tags"](#).

Description (optional)

To track and monitor your job, you can also provide a description of up to 256 characters. Amazon S3 includes this description whenever it returns information about a job or displays job details on the Amazon S3 console. You can then easily sort and filter jobs according to the descriptions that you assigned. Descriptions don't need to be unique, so you can use descriptions as categories (for example, "Weekly Log Copy Jobs") to help you track groups of similar jobs.

Specifying a manifest

A manifest is an Amazon S3 object that contains the object keys that you want Amazon S3 to act upon. You can supply a manifest in one of the following ways:

- Create a new manifest file manually.
- Use an existing manifest.
- Direct Batch Operations to generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for batch replication jobs that you create in the Amazon S3 console, or for any job type that you create by using the AWS CLI, AWS SDKs, or Amazon S3 REST API.

Note

Regardless of how you specify your manifest, the list itself must be stored in a general purpose bucket. Batch Operations can't import existing manifests from, or save generated manifests to directory buckets. Objects described within the manifest, however, can be stored in directory buckets. For more information, see [Directory buckets](#).

Creating a manifest file

To create a manifest file manually, you specify the manifest object key, ETag (entity tag), and optional version ID in a CSV-formatted list. The contents of the manifest must be URL-encoded.

By default, Amazon S3 automatically uses server-side encryption with Amazon S3 managed keys (SSE-S3) to encrypt a manifest that's uploaded to an Amazon S3 bucket. Manifests that use server-side encryption with customer-provided keys (SSE-C) are not supported. Manifests that use server-

side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) are supported only when you're using CSV-formatted inventory reports.

Your manifest must contain the bucket name, object key, and optionally, the object version for each object. Any other fields in the manifest are not used by S3 Batch Operations.

Note

If the objects in your manifest are in a versioned bucket, specifying the version IDs for the objects directs Batch Operations to perform the operation on a specific version. If no version IDs are specified, Batch Operations performs the operation on the latest version of the objects. If your manifest includes a version ID field, you must provide a version ID for all objects in the manifest.

The following is an example manifest in CSV format without version IDs.

```
Examplebucket,objectkey1  
Examplebucket,objectkey2  
Examplebucket,objectkey3  
Examplebucket,photos/jpgs/objectkey4  
Examplebucket,photos/jpgs/newjersey/objectkey5  
Examplebucket,object%20key%20with%20spaces
```

The following is an example manifest in CSV format that includes version IDs.

```
Examplebucket,objectkey1,PZ9ibn9D5lP6p298B7S9_ceqx1n5EJ0p  
Examplebucket,objectkey2,YY_ouuAJByNW1LRBffMfxMge7XQWxMBF  
Examplebucket,objectkey3,jbo9_jhdPEyB4Rim0xWS0kU0EoNrU_oI  
Examplebucket,photos/jpgs/objectkey4,6EqlikJJxLTsHsnbZbSRffn24_eh5Ny4  
Examplebucket,photos/jpgs/newjersey/objectkey5,imHf3FAiRsvBW_EHB8G0u.NHunH01gVs  
Examplebucket,object%20key%20with%20spaces,9HkPvDaZY5MVbMhn6TMn1YTb5ArQAo3w
```

Specifying an existing manifest file

You can specify a manifest file for a create job request by using one of the following two formats:

- **Amazon S3 Inventory report** – Must be a CSV-formatted Amazon S3 Inventory report. You must specify the manifest.json file that is associated with the inventory report. For more information about inventory reports, see [Amazon S3 Inventory](#). If the inventory report includes version IDs, S3 Batch Operations operates on the specific object versions.

Note

- S3 Batch Operations supports CSV *inventory reports* that are encrypted with SSE-KMS.
 - If you submit an inventory report manifest that's encrypted with SSE-KMS, your IAM policy must include the permissions "kms:Decrypt" and "kms:GenerateDataKey" for the manifest.json object and all associated CSV data files.
- **CSV file** – Each row in the file must include the bucket name, object key, and optionally, the object version. Object keys must be URL-encoded, as shown in the following examples. The manifest must either include version IDs for all objects or omit version IDs for all objects. For more information about the CSV manifest format, see [JobManifestSpec](#) in the *Amazon Simple Storage Service API Reference*.

Note

S3 Batch Operations doesn't support CSV *manifest files* that are encrypted with SSE-KMS.

Important

When you're using a manually created manifest and a versioned bucket, we recommend that you specify the version IDs for the objects. When you create a job, S3 Batch Operations parses the entire manifest before running the job. However, it doesn't take a "snapshot" of the state of the bucket.

Because manifests can contain billions of objects, jobs might take a long time to run, which can affect which version of an object that the job acts upon. Suppose that you overwrite an object with a new version while a job is running and you didn't specify a version ID for that object. In this case, Amazon S3 performs the operation on the latest version of the object, not on the version that existed when you created the job. The only way to avoid this behavior is to specify version IDs for the objects that are listed in the manifest.

Generating a manifest automatically

You can direct Amazon S3 to generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for batch replication jobs that you

create in the Amazon S3 console, or for any job type that you create by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information about Batch Replication, see [Replicating existing objects with S3 Batch Replication](#).

To generate a manifest automatically, you specify the following elements as part of your job creation request:

- Information about the bucket that contains your source objects, including the bucket owner and Amazon Resource Name (ARN)
- Information about the manifest output, including a flag to create a manifest file, the output bucket owner, the ARN, the prefix, the file format, and the encryption type
- Optional criteria to filter objects by creation date, key name, size, storage class, and tags

Object filter criteria

To filter the list of objects to be included in an automatically generated manifest, you can specify the following criteria. For more information, see [JobManifestGeneratorFilter](#) in the *Amazon S3 API Reference*.

CreatedAfter

If provided, the generated manifest includes only source bucket objects that were created after this time.

CreatedBefore

If provided, the generated manifest includes only source bucket objects that were created before this time.

EligibleForReplication

If provided, the generated manifest includes objects only if they are eligible for replication according to the replication configuration on the source bucket.

KeyNameConstraint

If provided, the generated manifest includes only source bucket objects whose object keys match the string constraints specified for **MatchAnySubstring**, **MatchAnyPrefix**, and **MatchAnySuffix**.

MatchAnySubstring – If provided, the generated manifest includes objects if the specified string appears anywhere within the object key string.

MatchAnyPrefix – If provided, the generated manifest includes objects if the specified string appears at the start of the object key string.

MatchAnySuffix – If provided, the generated manifest includes objects if the specified string appears at the end of the object key string.

MatchAnyStorageClass

If provided, the generated manifest includes only source bucket objects that are stored with the specified storage class.

ObjectReplicationStatuses

If provided, the generated manifest includes only source bucket objects that have one of the specified replication statuses.

ObjectSizeGreaterThanBytes

If provided, the generated manifest includes only source bucket objects whose file size is greater than the specified number of bytes.

ObjectSizeLessThanBytes

If provided, the generated manifest includes only source bucket objects whose file size is less than the specified number of bytes.

Note

You can't clone most jobs that have automatically generated manifests. Batch replication jobs can be cloned, except when they use the KeyNameConstraint, MatchAnyStorageClass, ObjectSizeGreaterThanBytes, or ObjectSizeLessThanBytes manifest filter criteria.

The syntax for specifying manifest criteria varies depending on the method that you use to create your job. For examples, see [Creating a job](#).

Creating a job

You can create S3 Batch Operations jobs by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

For more information about creating a job request, see [Batch Operations job request elements](#).

Prerequisites

Before you create a Batch Operations job, confirm that you have configured the relevant permissions. For more information, see [Granting permissions for Amazon S3 Batch Operations](#).

Using the S3 console

To create a batch job

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose **Batch Operations** on the navigation pane of the Amazon S3 console.
3. Choose **Create job**.
4. Choose the **Region** where you want to create your job.
5. Under **Manifest format**, choose the type of manifest object to use.
 - If you choose **S3 inventory report**, enter the path to the manifest.json object that Amazon S3 generated as part of the CSV-formatted Inventory report, and optionally the version ID for the manifest object if you want to use a version other than the most recent.
 - If you choose **CSV**, enter the path to a CSV-formatted manifest object. The manifest object must follow the format described in the console. You can optionally include the version ID for the manifest object if you want to use a version other than the most recent.

 **Note**

The Amazon S3 console supports automatic manifest generation for batch replication jobs only. For all other job types, if you want Amazon S3 to generate a manifest automatically based on filter criteria that you specify, you must configure your job using the AWS CLI, AWS SDKs, or Amazon S3 REST API.

6. Choose **Next**.
7. Under **Operation**, choose the operation that you want to perform on all objects listed in the manifest. Fill out the information for the operation you chose and then choose **Next**.
8. Fill out the information for **Configure additional options** and then choose **Next**.
9. For **Review**, verify the settings. If you need to make changes, choose **Previous**. Otherwise, choose **Create Job**.

Using the AWS CLI

Specify manifest

The following example shows how to create an S3 Batch Operations S3PutObjectTagging job that acts on objects that are listed in an existing manifest file.

To create a Batch Operations S3PutObjectTagging job

1. Use the following commands to create an AWS Identity and Access Management (IAM) role, and then create an IAM policy to assign the relevant permissions. The following role and policy grant Amazon S3 permission to add object tags, which you will need when you create the job in a subsequent step.
 - a. Use the following example command to create an IAM role for Batch Operations to use. To use this example command, replace *S3BatchJobRole* with the name that you want to give to the role.

```
aws iam create-role \
--role-name S3BatchJobRole \
--assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "batchoperations.s3.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}'
```

Record the role's Amazon Resource Name (ARN). You will need the ARN when you create a job.

- b. Use the following example command to create an IAM policy with the necessary permissions and attach it to the IAM role that you created in the previous step. For more information about the necessary permissions, see [Granting permissions for Amazon S3 Batch Operations](#).

Note

Batch Operations jobs that perform actions on directory buckets require specific permissions. For more information, see [AWS Identity and Access Management \(IAM\) for S3 Express One Zone](#).

To use this example command, replace the *user input placeholders* as follows:

- Replace *S3BatchJobRole* with the name of your IAM role. Make sure that this name matches the name that you used earlier.
- Replace *PutObjectTaggingBatchJobPolicy* with the name that you want to give your IAM policy.
- Replace *DOC-EXAMPLE-DESTINATION-BUCKET* with the name of the bucket that contains the objects that you want to apply tags to.
- Replace *DOC-EXAMPLE-MANIFEST-BUCKET* with the name of the bucket that contains the manifest.
- Replace *DOC-EXAMPLE-REPORT-BUCKET* with the name of the bucket where you want the completion report to be delivered to.

```
aws iam put-role-policy \
--role-name S3BatchJobRole \
--policy-name PutObjectTaggingBatchJobPolicy \
--policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObjectTagging",
                "s3:PutObjectVersionTagging"
            ],
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"
        },
        {
            "Effect": "Allow",
            "Action": [
```

```
        "s3:GetObject",
        "s3GetObjectVersion",
        "s3:GetBucketLocation"
    ],
    "Resource": [
        "arn:aws:s3:::DOC-EXAMPLE-MANIFEST-BUCKET",
        "arn:aws:s3:::DOC-EXAMPLE-MANIFEST-BUCKET/*"
    ]
},
{
    "Effect":"Allow",
    "Action":[
        "s3:PutObject",
        "s3:GetBucketLocation"
    ],
    "Resource": [
        "arn:aws:s3:::DOC-EXAMPLE-REPORT-BUCKET",
        "arn:aws:s3:::DOC-EXAMPLE-REPORT-BUCKET/*"
    ]
}
]
}'
```

2. Use the following example command to create an S3PutObjectTagging job.

The manifest.csv file provides a list of bucket and object key values. The job applies the specified tags to the objects that are identified in the manifest. The ETag is the ETag of the manifest.csv object, which you can get from the Amazon S3 console. This request specifies the no-confirmation-required parameter, so that you can run the job without having to confirm it with the update-job-status command. For more information, see [create-job](#) in the *AWS CLI Command Reference*.

To use this example command, replace the *user input placeholders* with your own information. Replace *IAM-role* with the ARN of the IAM role that you created earlier.

```
aws s3control create-job \
--region us-west-2 \
--account-id acct-id \
--operation '{"S3PutObjectTagging": { "TagSet": [{"Key": "keyOne", "Value": "ValueOne"}] }}' \
--manifest '{"Spec":{"Format":"S3BatchOperations_CSV_20180820","Fields": ["Bucket","Key"]}}, "Location":
```

```
{"ObjectArn":"arn:aws:s3:::my_manifests/  
manifest.csv","ETag":"60e460c9d1046e73f7dde5043ac3ae85"}]' \  
--report '{"Bucket": "arn:aws:s3:::DOC-EXAMPLE-REPORT-  
BUCKET", "Prefix": "final-reports",  
"Format": "Report_CSV_20180820", "Enabled": true, "ReportScope": "AllTasks"}' \  
--priority 42 \  
--role-arn IAM-role \  
--client-request-token $(uuidgen) \  
--description "job description" \  
--no-confirmation-required
```

In response, Amazon S3 returns a job ID (for example, 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c). You will need the job ID to identify, monitor, and modify the job.

Generate manifest

The following example shows how to create an S3 Batch Operations S3DeleteObjectTagging job that automatically generates a manifest based on your object filter criteria. This criteria includes the creation date, key name, size, storage class, and tags.

To create a Batch Operations S3DeleteObjectTagging job

1. Use the following commands to create an AWS Identity and Access Management (IAM) role, and then create an IAM policy to assign permissions. The following role and policy grant Amazon S3 permission to delete object tags, which you will need when you create the job in a subsequent step.
 - a. Use the following example command to create an IAM role for Batch Operations to use. To use this example command, replace *S3BatchJobRole* with the name that you want to give to the role.

```
aws iam create-role \  
--role-name S3BatchJobRole \  
--assume-role-policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "batchoperations.s3.amazonaws.com"
```

```
        },
        "Action":"sts:AssumeRole"
    }
}'
```

Record the role's Amazon Resource Name (ARN). You will need the ARN when you create a job.

- b. Use the following example command to create an IAM policy with the necessary permissions and attach it to the IAM role that you created in the previous step. For more information about the necessary permissions, see [Granting permissions for Amazon S3 Batch Operations](#).

 **Note**

Batch Operations jobs that perform actions on directory buckets require specific permissions. For more information, see [AWS Identity and Access Management \(IAM\) for S3 Express One Zone](#).

To use this example command, replace the *user input placeholders* as follows:

- Replace *S3BatchJobRole* with the name of your IAM role. Make sure that this name matches the name that you used earlier.
- Replace *DeleteObjectTaggingBatchJobPolicy* with the name that you want to give your IAM policy.
- Replace *DOC-EXAMPLE-DESTINATION-BUCKET* with the name of the bucket that contains the objects that you want to apply tags to.
- Replace *DOC-EXAMPLE-MANIFEST-OUTPUT-BUCKET* with the name of the bucket where you want to save the manifest.
- Replace *DOC-EXAMPLE-REPORT-BUCKET* with the name of the bucket where you want the completion report to be delivered to.

```
aws iam put-role-policy \
--role-name S3BatchJobRole \
--policy-name DeleteObjectTaggingBatchJobPolicy \
--policy-document '{
```

```
"Version":"2012-10-17",
"Statement": [
    {
        "Effect":"Allow",
        "Action":[
            "s3>DeleteObjectTagging",
            "s3>DeleteObjectVersionTagging"
        ],
        "Resource": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"
    },
    {
        "Effect":"Allow",
        "Action":[
            "s3:PutInventoryConfiguration"
        ],
        "Resource": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET"
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3>ListBucket"
        ],
        "Resource": [
            "arn:aws:s3:::DOC-EXAMPLE-MANIFEST-OUTPUT-BUCKET",
            "arn:aws:s3:::DOC-EXAMPLE-MANIFEST-OUTPUT-BUCKET/*"
        ]
    },
    {
        "Effect":"Allow",
        "Action": [
            "s3:PutObject",
            "s3>ListBucket"
        ],
        "Resource": [
            "arn:aws:s3:::DOC-EXAMPLE-REPORT-BUCKET",
            "arn:aws:s3:::DOC-EXAMPLE-REPORT-BUCKET/*",
            "arn:aws:s3:::DOC-EXAMPLE-MANIFEST-OUTPUT-BUCKET/*"
        ]
    }
]
```

2. Use the following example command to create the S3DeleteObjectTagging job.

In this example, the values in the --report section specify the bucket, prefix, format, and scope of the job report that will be generated. The --manifest -generator section specifies information about the source bucket that contains the objects the job will act upon, information about the manifest output list that will be generated for the job, and filter criteria to narrow the scope of objects to be included in the manifest by creation date, name constraints, size, and storage class. The command also specifies the job's priority, IAM role, and AWS Region.

For more information, see [create-job](#) in the *AWS CLI Command Reference*.

To use this example command, replace the *user input placeholders* with your own information. Replace *IAM-role* with the ARN of the IAM role that you created earlier.

```
aws s3control create-job \
--account-id 012345678901 \
--operation '{
    "S3DeleteObjectTagging": {}
}' \
--report '{
    "Bucket": "arn:aws:s3:::DOC-EXAMPLE-REPORT-BUCKET",
    "Prefix": "reports",
    "Format": "Report_CSV_20180820",
    "Enabled": true,
    "ReportScope": "AllTasks"
}' \
--manifest-generator '{
    "S3JobManifestGenerator": {
        "ExpectedBucketOwner": "012345678901",
        "SourceBucket": "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET",
        "EnableManifestOutput": true,
        "ManifestOutputLocation": {
            "ExpectedManifestBucketOwner": "012345678901",
            "Bucket": "arn:aws:s3:::DOC-EXAMPLE-MANIFEST-OUTPUT-BUCKET",
            "ManifestPrefix": "prefix",
            "ManifestFormat": "S3InventoryReport_CSV_20211130"
        },
        "Filter": {
            "CreatedAfter": "2023-09-01",
            "CreatedBefore": "2023-10-01",
            "KeyNameConstraint": {
                "MinLength": 3,
                "MaxLength": 100
            }
        }
    }
}'
```

```
        "MatchAnyPrefix": [
            "prefix"
        ],
        "MatchAnySuffix": [
            "suffix"
        ]
    },
    "ObjectSizeGreater ThanBytes": 100,
    "ObjectSizeLessThanBytes": 200,
    "MatchAnyStorageClass": [
        "STANDARD",
        "STANDARD_IA"
    ]
}
}' \
--priority 2 \
--role-arn IAM-role \
--region us-east-1
```

In response, Amazon S3 returns a job ID (for example, `00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c`). You will need this job ID to identify, monitor, or modify the job.

Using the AWS SDK for Java

Specify manifest

The following example shows how to create an S3 Batch Operations `S3PutObjectTagging` job that acts on objects that are listed in an existing manifest file. To use this example, replace the *user input placeholders* with your own information.

Example

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
```

```
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.*;

import java.util.UUID;
import java.util.ArrayList;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateJob {
    public static void main(String[] args) {
        String accountId = "Account ID";
        String iamRoleArn = "IAM Role ARN";
        String reportBucketName = "arn:aws:s3:::DOC-EXAMPLE-REPORT-BUCKET";
        String uuid = UUID.randomUUID().toString();

        ArrayList tagSet = new ArrayList<S3Tag>();
        tagSet.add(new S3Tag().withKey("keyOne").withValue("ValueOne"));

        try {
            JobOperation jobOperation = new JobOperation()
                .withS3PutObjectTagging(new S3SetObjectTaggingOperation()
                    .withTagSet(tagSet))
        };

        JobManifest manifest = new JobManifest()
            .withSpec(new JobManifestSpec()
                .withFormat("S3BatchOperations_CSV_20180820")
                .withFields(new String[]{
                    "Bucket", "Key"
                }))
            .withLocation(new JobManifestLocation()
                .withObjectArn("arn:aws:s3:::my_manifests/manifest.csv")
                .withETag("60e460c9d1046e73f7dde5043ac3ae85"));
        JobReport jobReport = new JobReport()
            .withBucket(reportBucketName)
            .withPrefix("reports")
            .withFormat("Report_CSV_20180820")
            .withEnabled(true)
            .withReportScope("AllTasks");

        AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
            .withCredentials(new ProfileCredentialsProvider())
            .withRegion(US_WEST_2)
```

```
        .build();

        s3ControlClient.createJob(new CreateJobRequest()
            .withAccountId(accountId)
            .withOperation(jobOperation)
            .withManifest(manifest)
            .withReport(jobReport)
            .withPriority(42)
            .withRoleArn(iamRoleArn)
            .withClientRequestToken(uuid)
            .withDescription("job description")
            .withConfirmationRequired(false)
        );

    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

Generate manifest

The following example shows how to create an S3 Batch Operations `s3PutObjectCopy` job that automatically generates a manifest based on object filter criteria, including the creation date, key name, and size. To use this example, replace the *user input placeholders* with your own information.

Example

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWS3Control;
import com.amazonaws.services.s3control.AWS3ControlClient;
```

```
import com.amazonaws.services.s3control.model.CreateJobRequest;
import com.amazonaws.services.s3control.model.CreateJobResult;
import com.amazonaws.services.s3control.model.JobManifestGenerator;
import com.amazonaws.services.s3control.model.JobManifestGeneratorFilter;
import com.amazonaws.services.s3control.model.JobOperation;
import com.amazonaws.services.s3control.model.JobReport;
import com.amazonaws.services.s3control.model.KeyNameConstraint;
import com.amazonaws.services.s3control.model.S3JobManifestGenerator;
import com.amazonaws.services.s3control.model.S3ManifestOutputLocation;
import com.amazonaws.services.s3control.model.S3SetObjectTaggingOperation;
import com.amazonaws.services.s3control.model.S3Tag;

import java.time.Instant;
import java.util.Date;
import java.util.UUID;
import java.util.ArrayList;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class test {
    public static void main(String[] args) {
        String accountId = "012345678901";
        String iamRoleArn = "arn:aws:iam::012345678901:role/ROLE";
        String sourceBucketName = "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET";
        String reportBucketName = "arn:aws:s3:::DOC-EXAMPLE-REPORT-BUCKET";
        String manifestOutputBucketName = "arn:aws:s3:::DOC-EXAMPLE-MANIFEST-
OUTPUT-BUCKET";
        String uuid = UUID.randomUUID().toString();
        long minimumObjectSize = 100L;

        ArrayList<S3Tag> tagSet = new ArrayList<>();
        tagSet.add(new S3Tag().withKey("keyOne").withValue("ValueOne"));

        ArrayList<String> prefixes = new ArrayList<>();
        prefixes.add("s3KeyStartsWith");

        try {
            JobOperation jobOperation = new JobOperation()
                .withS3PutObjectTagging(new S3SetObjectTaggingOperation()
                    .withTagSet(tagSet)
                );
            S3ManifestOutputLocation manifestOutputLocation = new
S3ManifestOutputLocation()
                .withBucket(manifestOutputBucketName)
```

```
.withManifestPrefix("manifests")
.withExpectedManifestBucketOwner(accountId)
.withManifestFormat("S3InventoryReport_CSV_20211130");
```

```
JobManifestGeneratorFilter jobManifestGeneratorFilter = new
JobManifestGeneratorFilter()
    .withEligibleForReplication(true)
    .withKeyNameConstraint(
        new KeyNameConstraint()
            .withMatchAnyPrefix(prefixes))
    .withCreatedBefore(Date.from(Instant.now()))
    .withObjectSizeGreaterThanBytes(minimumObjectSize);
```

```
S3JobManifestGenerator s3JobManifestGenerator = new
S3JobManifestGenerator()
    .withEnableManifestOutput(true)
    .withManifestOutputLocation(manifestOutputLocation)
    .withFilter(jobManifestGeneratorFilter)
    .withSourceBucket(sourceBucketName);
```

```
JobManifestGenerator jobManifestGenerator = new
JobManifestGenerator()
    .withS3JobManifestGenerator(s3JobManifestGenerator);
```

```
JobReport jobReport = new JobReport()
    .withBucket(reportBucketName)
    .withPrefix("reports")
    .withFormat("Report_CSV_20180820")
    .withEnabled(true)
    .withReportScope("AllTasks");
```

```
AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(US_WEST_2)
    .build();
```

```
CreateJobResult createJobResult = s3ControlClient.createJob(new
CreateJobRequest()
    .withAccountId(accountId)
    .withOperation(jobOperation)
    .withManifestGenerator(jobManifestGenerator)
    .withReport(jobReport)
    .withPriority(42)
    .withRoleArn(iamRoleArn)
```

```
        .withClientRequestToken(uuid)
        .withDescription("job description")
        .withConfirmationRequired(true)
    );

    System.out.println("Created job " + createJobResult.getJobId());

} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't
process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Using the REST API

You can use the REST API to create a Batch Operations job. For more information, see [CreateJob](#) in the *Amazon Simple Storage Service API Reference*.

Job responses

If the CreateJob request succeeds, Amazon S3 returns a job ID. The job ID is a unique identifier that Amazon S3 generates automatically so that you can identify your Batch Operations job and monitor its status.

When you create a job through the AWS CLI, AWS SDKs, or REST API, you can set S3 Batch Operations to begin processing the job automatically. The job runs as soon as it's ready instead of waiting behind higher-priority jobs.

When you create a job through the Amazon S3 console, you must review the job details and confirm that you want to run the job before Batch Operations can begin to process it. If a job remains in the suspended state for over 30 days, it will fail.

Operations supported by S3 Batch Operations

S3 Batch Operations supports several different operations. The topics in this section describe each of these operations.

Copy objects

The **Copy** operation copies each object that is specified in the manifest. You can copy objects to a bucket in the same AWS Region or to a bucket in a different Region. S3 Batch Operations supports most options available through Amazon S3 for copying objects. These options include setting object metadata, setting permissions, and changing an object's storage class.

You can also use the Copy operation to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. For more information, see [Encrypting objects with Amazon S3 Batch Operations](#).

When you copy objects, you can change the checksum algorithm used to calculate the checksum of the object. If objects don't have an additional checksum calculated, you can also add one by specifying the checksum algorithm for Amazon S3 to use. For more information, see [Checking object integrity](#).

For more information about copying objects in Amazon S3 and the required and optional parameters, see [Copying objects](#) in this guide and [CopyObject](#) in the *Amazon Simple Storage Service API Reference*.

Restrictions and limitations

- All source objects must be in one bucket.
- All destination objects must be in one bucket.
- You must have read permissions for the source bucket and write permissions for the destination bucket.
- Objects to be copied can be up to 5 GB in size.
- If you try to copy objects from the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive classes to the S3 Standard storage class, you need to first restore these objects. For more information, see [Restoring an archived object](#).
- Copy jobs must be created in the destination Region, which is the Region you intend to copy the objects to.

- All Copy options are supported except for conditional checks on ETags and server-side encryption with customer-provided encryption keys (SSE-C).
- If the buckets are unversioned, you will overwrite objects with the same key names.
- Objects are not necessarily copied in the same order as they appear in the manifest. For versioned buckets, if preserving current/non-current version order is important, you should copy all noncurrent versions first. Then, after the first job is complete, copy the current versions in a subsequent job.
- Copying objects to the Reduced Redundancy Storage (RRS) class is not supported.

Copying objects using S3 Batch Operations

You can use S3 Batch Operations to create a PUT copy job to copy objects within the same account or to a different destination account. The following sections contain examples of how to store and use a manifest that is in a different account. In the first section, you can use Amazon S3 Inventory to deliver the inventory report to the destination account for use during job creation or, you can use a comma-separated values (CSV) manifest in the source or destination account, as shown in the second example. The third example shows how to use the Copy operation to activate S3 Bucket Key encryption on existing objects.

Copy Operation Examples

- [Using an inventory report delivered to the destination account to copy objects across AWS accounts](#)
- [Using a CSV manifest stored in the source account to copy objects across AWS accounts](#)
- [Using S3 Batch Operations to encrypt objects with S3 Bucket Keys](#)

Using an inventory report delivered to the destination account to copy objects across AWS accounts

You can use Amazon S3 Inventory to create an inventory report and use the report to create a list of objects to copy with S3 Batch Operations. For more information about using a CSV manifest in the source or destination account, see [the section called “Using a CSV manifest to copy objects across AWS accounts”](#).

Amazon S3 Inventory generates inventories of the objects in a bucket. The resulting list is published to an output file. The bucket that is inventoried is called the *source bucket*, and the bucket where the inventory report file is stored is called the *destination bucket*.

The Amazon S3 Inventory report can be configured to be delivered to another AWS account. This allows S3 Batch Operations to read the inventory report when the job is created in the destination account.

For more information about Amazon S3 Inventory source and destination buckets, see [Source and destination buckets](#).

The easiest way to set up an inventory is by using the AWS Management Console, but you can also use the REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

The following console procedure contains the high-level steps for setting up permissions for an S3 Batch Operations job. In this procedure, you copy objects from a source account to a destination account, with the inventory report stored in the destination account.

To set up Amazon S3 Inventory for source and destination buckets owned by different accounts

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose a destination bucket to store the inventory report in.

Decide on a destination manifest bucket for storing the inventory report. In this procedure, the *destination account* is the account that owns both the destination manifest bucket and the bucket that the objects are copied to.

3. Configure an inventory to list the objects in a source bucket and publish the list to the destination manifest bucket.

Configure an inventory list for a source bucket. When you do this, you specify the destination bucket where you want the list to be stored. The inventory report for the source bucket is published to the destination bucket. In this procedure, the *source account* is the account that owns the source bucket.

For information about how to use the console to configure an inventory or how to encrypt an inventory list file, see [Configuring Amazon S3 Inventory](#).

Choose **CSV** for the output format.

When you enter information for the destination bucket, choose **Buckets in another account**. Then enter the name of the destination manifest bucket. Optionally, you can enter the account ID of the destination account.

After the inventory configuration is saved, the console displays a message similar to the following:

Amazon S3 could not create a bucket policy on the destination bucket. Ask the destination bucket owner to add the following bucket policy to allow Amazon S3 to place data in that bucket.

The console then displays a bucket policy that you can use for the destination bucket.

4. Copy the destination bucket policy that appears on the console.
5. In the destination account, add the copied bucket policy to the destination manifest bucket where the inventory report is stored.
6. Create a role in the destination account that is based on the S3 Batch Operations trust policy.
For more information about the trust policy, see [Trust policy](#).

For more information about creating a role, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

Enter a name for the role (the example role uses the name `BatchOperationsDestinationRoleCOPY`). Choose the **S3** service, and then choose the **S3 bucket Batch Operations** use case, which applies the trust policy to the role.

Then choose **Create policy** to attach the following policy to the role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowBatchOperationsDestinationObjectCOPY",  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject",  
                "s3:PutObjectVersionAcl",  
                "s3:PutObjectAcl",  
                "s3:PutObjectVersionTagging",  
                "s3:PutObjectTagging",  
                "s3:GetObject",  
                "s3:GetObjectVersion",  
                "s3:GetObjectAcl",  
                "s3:GetObjectTagging",  
            ]  
        }  
    ]  
}
```

```
        "s3:GetObjectVersionAcl",
        "s3:GetObjectVersionTagging"
    ],
    "Resource": [
        "arn:aws:s3:::ObjectDestinationBucket/*",
        "arn:aws:s3:::ObjectSourceBucket/*",
        "arn:aws:s3:::ObjectDestinationManifestBucket/*"
    ]
}
]
```

The role uses the policy to grant `batchoperations.s3.amazonaws.com` permission to read the manifest in the destination bucket. It also grants permissions to GET objects, access control lists (ACLs), tags, and versions in the source object bucket. And it grants permissions to PUT objects, ACLs, tags, and versions into the destination object bucket.

7. In the source account, create a bucket policy for the source bucket that grants the role that you created in the previous step to GET objects, ACLs, tags, and versions in the source bucket. This step allows S3 Batch Operations to get objects from the source bucket through the trusted role.

The following is an example of the bucket policy for the source account.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowBatchOperationsSourceObjectCOPY",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::DestinationAccountNumber:role/
BatchOperationsDestinationRoleCOPY"
            },
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion",
                "s3:GetObjectAcl",
                "s3:GetObjectTagging",
                "s3:GetObjectVersionAcl",
                "s3:GetObjectVersionTagging"
            ],
        }
    ]
}
```

```
        "Resource": "arn:aws:s3:::ObjectSourceBucket/*"
    }
]
```

8. After the inventory report is available, create an S3 Batch Operations PUT object copy job in the destination account, choosing the inventory report from the destination manifest bucket. You need the ARN for the role that you created in the destination account.

For general information about creating a job, see [Creating an S3 Batch Operations job](#).

For information about creating a job using the console, see [Creating an S3 Batch Operations job](#).

Using a CSV manifest stored in the source account to copy objects across AWS accounts

You can use a CSV file that is stored in a different AWS account as a manifest for an S3 Batch Operations job. For using an S3 Inventory Report, see [the section called “Using an inventory report to copy objects across AWS accounts”](#).

The following procedure shows how to set up permissions when using an S3 Batch Operations job to copy objects from a source account to a destination account with the CSV manifest file stored in the source account.

To set up a CSV manifest stored in a different AWS account

1. Create a role in the destination account that is based on the S3 Batch Operations trust policy. In this procedure, the *destination account* is the account that the objects are being copied to.

For more information about the trust policy, see [Trust policy](#).

For more information about creating a role, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

If you create the role using the console, enter a name for the role (the example role uses the name BatchOperationsDestinationRoleCOPY). Choose the **S3** service, and then choose the **S3 bucket Batch Operations** use case, which applies the trust policy to the role.

Then choose **Create policy** to attach the following policy to the role.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "AllowBatchOperationsDestinationObjectCOPY",
    "Effect": "Allow",
    "Action": [
      "s3:PutObject",
      "s3:PutObjectVersionAcl",
      "s3:PutObjectAcl",
      "s3:PutObjectVersionTagging",
      "s3:PutObjectTagging",
      "s3:GetObject",
      "s3:GetObjectVersion",
      "s3:GetObjectAcl",
      "s3:GetObjectTagging",
      "s3:GetObjectVersionAcl",
      "s3:GetObjectVersionTagging"
    ],
    "Resource": [
      "arn:aws:s3:::ObjectDestinationBucket/*",
      "arn:aws:s3:::ObjectSourceBucket/*",
      "arn:aws:s3:::ObjectSourceManifestBucket/*"
    ]
  }
]
```

Using the policy, the role grants batchoperations.s3.amazonaws.com permission to read the manifest in the source manifest bucket. It grants permissions to GET objects, ACLs, tags, and versions in the source object bucket. It also grants permissions to PUT objects, ACLs, tags, and versions into the destination object bucket.

2. In the source account, create a bucket policy for the bucket that contains the manifest to grant the role that you created in the previous step to GET objects and versions in the source manifest bucket.

This step allows S3 Batch Operations to read the manifest using the trusted role. Apply the bucket policy to the bucket that contains the manifest.

The following is an example of the bucket policy to apply to the source manifest bucket.

{

```
"Version": "2012-10-17",
"Statement": [
{
  "Sid": "AllowBatchOperationsSourceManifestRead",
  "Effect": "Allow",
  "Principal": {
    "AWS": [
      "arn:aws:iam::DestinationAccountNumber:user/ConsoleUserCreatingJob",
      "arn:aws:iam::DestinationAccountNumber:role/
BatchOperationsDestinationRoleCOPY"
    ]
  },
  "Action": [
    "s3:GetObject",
    "s3:GetObjectVersion"
  ],
  "Resource": "arn:aws:s3:::ObjectSourceManifestBucket/*"
}
]
}
```

This policy also grants permissions to allow a console user who is creating a job in the destination account the same permissions in the source manifest bucket through the same bucket policy.

3. In the source account, create a bucket policy for the source bucket that grants the role you created to GET objects, ACLs, tags, and versions in the source object bucket. S3 Batch Operations can then get objects from the source bucket through the trusted role.

The following is an example of the bucket policy for the bucket that contains the source objects.

```
{
"Version": "2012-10-17",
"Statement": [
{
  "Sid": "AllowBatchOperationsSourceObjectCOPY",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::DestinationAccountNumber:role/
BatchOperationsDestinationRoleCOPY"
  },
  "Action": [
    "s3:GetObject",
    "s3:ListBucket"
  ],
  "Resource": "arn:aws:s3:::ObjectSourceBucket/*"
}
]
```

```
        "s3:GetObject",
        "s3:GetObjectVersion",
        "s3:GetObjectAcl",
        "s3:GetObjectTagging",
        "s3:GetObjectVersionAcl",
        "s3:GetObjectVersionTagging"
    ],
    "Resource": "arn:aws:s3:::ObjectSourceBucket/*"
}
]
}
```

4. Create an S3 Batch Operations job in the destination account. You need the Amazon Resource Name (ARN) for the role that you created in the destination account.

For general information about creating a job, see [Creating an S3 Batch Operations job](#).

For information about creating a job using the console, see [Creating an S3 Batch Operations job](#).

Using S3 Batch Operations to encrypt objects with S3 Bucket Keys

In this section, you use the Amazon S3 Batch Operations Copy operation to identify and activate S3 Bucket Keys encryption on existing objects. For more information about S3 Bucket Keys, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#) and [Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects](#).

Topics covered in this example include the following:

Topics

- [Prerequisites](#)
- [Step 1: Get your list of objects using Amazon S3 Inventory](#)
- [Step 2: Filter your object list with S3 Select](#)
- [Step 3: Set up and run your S3 Batch Operations job](#)
- [Summary](#)

Prerequisites

To follow along with the steps in this procedure, you must have an AWS account and at least one S3 bucket to hold your working files and encrypted results. You might also find much of the existing S3 Batch Operations documentation useful, including the following topics:

- [S3 Batch Operations basics](#)
- [Creating an S3 Batch Operations job](#)
- [Operations supported by S3 Batch Operations](#)
- [Managing S3 Batch Operations jobs](#)

Step 1: Get your list of objects using Amazon S3 Inventory

To get started, identify the S3 bucket that contains the objects to encrypt, and get a list of its contents. An Amazon S3 Inventory report is the most convenient and affordable way to do this. The report provides the list of the objects in a bucket along with associated metadata. The **source bucket** refers to the inventoried bucket, and the **destination bucket** refers to the bucket where you store the inventory report file. For more information about Amazon S3 Inventory source and destination buckets, see [Amazon S3 Inventory](#).

The easiest way to set up an inventory is by using the AWS Management Console. But you can also use the REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs. Before following these steps, be sure to sign in to the console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>. If you encounter permission denied errors, add a bucket policy to your destination bucket. For more information, see [Grant permissions for S3 Inventory and S3 analytics](#).

To get a list of objects using S3 Inventory

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Buckets**, and choose a bucket that contains objects to encrypt.
3. On the **Management** tab, navigate to the **Inventory configurations** section, and choose **Create inventory configuration**.
4. Give your new inventory a name, enter the name of the destination S3 bucket, and optionally create a destination prefix for Amazon S3 to assign objects in that bucket.
5. For **Output format**, choose **CSV**.

6. (Optional) In the **Additional fields – optional** section, choose **Encryption** and any other report fields that interest you. Set the frequency for report deliveries to **Daily** so that the first report is delivered to your bucket sooner.
7. Choose **Create** to save your configuration.

Amazon S3 can take up to 48 hours to deliver the first report, so check back when the first report arrives. After you receive your first report, proceed to the next section to filter your S3 Inventory report's contents. If you no longer want to receive inventory reports for this bucket, delete your S3 Inventory configuration. Otherwise, S3 delivers reports on a daily or weekly schedule.

An inventory list isn't a single point-in-time view of all objects. Inventory lists are a rolling snapshot of bucket items, which are eventually consistent (for example, the list might not include recently added or deleted objects). Combining S3 Inventory and S3 Batch Operations works best when you work with static objects, or with an object set that you created two or more days ago. To work with more recent data, use the [ListObjectsV2](#) (GET Bucket) API operation to build your list of objects manually. If needed, repeat the process for the next few days or until your inventory report shows the desired status for all keys.

Step 2: Filter your object list with S3 Select

After you receive your S3 Inventory report, you can filter the report's contents to list only the objects that aren't encrypted with S3 Bucket Keys. If you want all your bucket's objects encrypted with S3 Bucket Keys, you can ignore this step. However, filtering your S3 Inventory report at this stage saves you the time and expense of re-encrypting objects that you previously encrypted.

Although the following steps show how to filter using [Amazon S3 Select](#), you can also use [Amazon Athena](#). To decide which tool to use, look at your S3 Inventory report's `manifest.json` file. This file lists the number of data files that are associated with that report. If the number is large, use Amazon Athena because it runs across multiple S3 objects, whereas S3 Select works on one object at a time. For more information about using Amazon S3 and Athena together, see [Querying Amazon S3 Inventory with Amazon Athena](#) and [Using Athena](#) in the blog post [Encrypting objects with Amazon S3 Batch Operations](#).

To filter your S3 Inventory report using S3 Select

1. Open the `manifest.json` file from your inventory report and look at the `fileSchema` section of the JSON. This informs the query that you run on the data.

The following JSON is an example `manifest.json` file for a CSV-formatted inventory on a bucket with versioning enabled. Depending on how you configured your inventory report, your manifest might look different.

```
{  
    "sourceBucket": "batchoperationsdemo",  
    "destinationBucket": "arn:aws:s3:::testbucket",  
    "version": "2021-05-22",  
    "creationTimestamp": "1558656000000",  
    "fileFormat": "CSV",  
    "fileSchema": "Bucket, Key, VersionId, IsLatest, IsDeleteMarker,  
BucketKeyStatus",  
    "files": [  
        {  
            "key": "demoinv/batchoperationsdemo/DemoInventory/data/009a40e4-  
f053-4c16-8c75-6100f8892202.csv.gz",  
            "size": 72691,  
            "MD5checksum": "c24c831717a099f0ebe4a9d1c5d3935c"  
        }  
    ]  
}
```

If versioning isn't activated on the bucket, or if you choose to run the report for the latest versions, the `fileSchema` is Bucket, Key, and BucketKeyStatus.

If versioning *is* activated, depending on how you set up the inventory report, the `fileSchema` might include the following: Bucket, Key, VersionId, IsLatest, IsDeleteMarker, BucketKeyStatus. So pay attention to columns 1, 2, 3, and 6 when you run your query.

S3 Batch Operations needs the bucket, key, and version ID as inputs to perform the job, in addition to the field to search by, which is BucketKeyStatus. You don't need the version ID field, but it helps to specify it when you operate on a versioned bucket. For more information, see [Working with objects in a versioning-enabled bucket](#).

2. Locate the data files for the inventory report. The `manifest.json` object lists the data files under **files**.
3. After you locate and select the data file in the S3 console, choose **Actions**, and then choose **Query with S3 Select**.
4. Keep the preset **CSV**, **Comma**, and **GZIP** fields selected, and choose **Next**.

5. To review your inventory report's format before proceeding, choose **Show file preview**.
6. Enter the columns to reference in the SQL expression field, and choose **Run SQL**. The following expression returns columns 1–3 for all objects without an S3 Bucket Key configured.

```
select s._1, s._2, s._3 from s3object s where s._6 = 'DISABLED'
```

The following are example results.

```

```

7. Download the results, save them into a CSV format, and upload them to Amazon S3 as your list of objects for the S3 Batch Operations job.
8. If you have multiple manifest files, run **Query with S3 Select** on those also. Depending on the size of the results, you could combine the lists and run a single S3 Batch Operations job or run each list as a separate job.

Consider the [price](#) of running each S3 Batch Operations job when you decide the number of jobs to run.

Step 3: Set up and run your S3 Batch Operations job

Now that you have your filtered CSV lists of S3 objects, you can begin the S3 Batch Operations job to encrypt the objects with S3 Bucket Keys.

A *job* refers collectively to the list (manifest) of objects provided, the operation performed, and the specified parameters. The easiest way to encrypt this set of objects is by using the PUT copy operation and specifying the same destination prefix as the objects listed in the manifest. This either overwrites the existing objects in an unversioned bucket or, with versioning turned on, creates a newer, encrypted version of the objects.

As part of copying the objects, specify that Amazon S3 should encrypt the object with SSE-KMS encryption and S3. This job copies the objects, so all your objects show an updated creation date upon completion, regardless of when you originally added them to S3. Also specify the other properties for your set of objects as part of the S3 Batch Operations job, including object tags and storage class.

Substeps

- [Set up your IAM policy](#)
 - [Set up your Batch Operations IAM role](#)
 - [Turn on S3 Bucket Keys for an existing bucket](#)
 - [Create your Batch Operations job](#)
 - [Run your Batch Operations job](#)
 - [Things to note](#)

Set up your IAM policy

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
 2. In the navigation pane, choose **Policy**, and then choose **Create Policy**.
 3. Choose the **JSON** tab. Choose **Edit policy** and add the example IAM policy that appears in the following code block.

After copying the policy example into your [IAM Console](#), replace the following:

- a. Replace *SOURCE_BUCKET_FOR_COPY* with the name of your source bucket.
 - b. Replace *DESTINATION_BUCKET_FOR_COPY* with the name of your destination bucket.
 - c. Replace *MANIFEST_KEY* with the name of your manifest object.
 - d. Replace *REPORT_BUCKET* with the name of the bucket where you want to save reports.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "CopyObjectsToEncrypt",  
      "Effect": "Allow",  
      "Action": [  
        "s3:PutObject",
```

```
        "s3:PutObjectTagging",
        "s3:PutObjectAcl",
        "s3:PutObjectVersionTagging",
        "s3:PutObjectVersionAcl",
        "s3:GetObject",
        "s3:GetObjectAcl",
        "s3:GetObjectTagging",
        "s3:GetObjectVersion",
        "s3:GetObjectVersionAcl",
        "s3:GetObjectVersionTagging"
    ],
    "Resource": [
        "arn:aws:s3::::SOURCE_BUCKET_FOR_COPY/*",
        "arn:aws:s3::::DESTINATION_BUCKET_FOR_COPY/*"
    ]
},
{
    "Sid": "ReadManifest",
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:GetObjectVersion"
    ],
    "Resource": "arn:aws:s3::::MANIFEST_KEY"
},
{
    "Sid": "WriteReport",
    "Effect": "Allow",
    "Action": [
        "s3:PutObject"
    ],
    "Resource": "arn:aws:s3::::REPORT_BUCKET/*"
}
]
}
```

4. Choose **Next: Tags**.
5. Add any tags that you want (optional), and choose **Next: Review**.
6. Add a policy name, optionally add a description, and choose **Create policy**.
7. Choose **Review policy and Save changes**.

8. With your S3 Batch Operations policy now complete, the console returns you to the IAM **Policies** page. Filter on the policy name, choose the button to the left of the policy name, choose **Policy actions**, and choose **Attach**.

To attach the newly created policy to an IAM role, select the appropriate users, groups, or roles in your account and choose **Attach policy**. This takes you back to the IAM console.

Set up your Batch Operations IAM role

1. On the [IAM Console](#), in the navigation pane, choose **Roles**, and then choose **Create role**.
2. Choose **AWS service, S3**, and **S3 Batch Operations**. Then choose **Next: Permissions**.
3. Start entering the name of the IAM **policy** that you just created. Select the check box by the policy name when it appears, and choose **Next: Tags**.
4. (Optional) Add tags or keep the key and value fields blank for this exercise. Choose **Next: Review**.
5. Enter a role name, and accept the default description or add your own. Choose **Create role**.
6. Ensure that the user creating the job has the permissions in the following example.

Replace **{ACCOUNT-ID}** with your AWS account ID and **{IAM_ROLE_NAME}** with the name that you plan to apply to the IAM role that you will create in the Batch Operations job creation step later. For more information, see [Granting permissions for Amazon S3 Batch Operations](#).

```
{  
    "Sid": "AddIamPermissions",  
    "Effect": "Allow",  
    "Action": [  
        "iam:GetRole",  
        "iam:PassRole"  
    ],  
    "Resource": "arn:aws:iam::ACCOUNT-ID:role/IAM_ROLE_NAME"  
}
```

Turn on S3 Bucket Keys for an existing bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket that you want to turn on an S3 Bucket Key for.
3. Choose **Properties**.

4. Under **Default encryption**, choose **Edit**.
5. Under **Encryption type**, you can choose between **Amazon S3 managed keys (SSE-S3)** and **AWS Key Management Service key (SSE-KMS)**.
6. If you chose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify the AWS KMS key through one of the following options.
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**. From the list of available keys, choose a symmetric encryption KMS key in the same Region as your bucket. Both the AWS managed key (aws/s3) and your customer managed keys appear in the list.
 - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
 - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.
7. Under **Bucket Key**, choose **Enable**, and then choose **Save changes**.

Now that an S3 Bucket Key is turned on at the bucket level, objects that are uploaded, modified, or copied into this bucket will inherit this encryption configuration by default. This includes objects that are copied by using Amazon S3 Batch Operations.

Create your Batch Operations job

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Batch Operations**, and then choose **Create Job**.
3. Choose the **Region** where you store your objects, and choose **CSV** as the manifest type.
4. Enter the path or navigate to the CSV manifest file that you created earlier from S3 Select (or Athena) results. If your manifest contains version IDs, select that box. Choose **Next**.
5. Choose the **Copy** operation, and choose the copy destination bucket. You can keep server-side encryption disabled. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies S3 Bucket Keys at the destination bucket.
6. (Optional) Choose a storage class and the other parameters as desired. The parameters that you specify in this step apply to all operations performed on the objects that are listed in the manifest. Choose **Next**.
7. To configure server-side encryption, follow these steps:
 - a. Under **Server-side encryption**, choose one of the following:

- To keep the bucket settings for default server-side encryption of objects when storing them in Amazon S3, choose **Do not specify an encryption key**. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies an S3 Bucket Key at the destination bucket.

 **Note**

If the bucket policy for the specified destination requires objects to be encrypted before storing them in Amazon S3, you must specify an encryption key. Otherwise, copying objects to the destination will fail.

- To encrypt objects before storing them in Amazon S3, choose **Specify an encryption key**.
- b. Under **Encryption settings**, if you choose **Specify an encryption key**, you must choose either **Use destination bucket settings for default encryption** or **Override destination bucket settings for default encryption**.
- c. If you choose **Override destination bucket settings for default encryption**, you must configure the following encryption settings.
- i. Under **Encryption type**, you must choose either **Amazon S3 managed keys (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**. SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. SSE-KMS provides you with more control over your key. For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#) and [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).
 - ii. If you choose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify your AWS KMS key through one of the following options.
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose a symmetric encryption KMS key in the same Region as your bucket. Both the AWS managed key (aws/s3) and your customer managed keys appear in the list.
 - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
 - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

- iii. Under **Bucket Key**, choose **Enable**. The copy operation applies an S3 Bucket Key at the destination bucket.
8. Give your job a description (or keep the default), set its priority level, choose a report type, and specify the **Path to completion report destination**.
9. In the **Permissions** section, be sure to choose the Batch Operations IAM role that you defined earlier. Choose **Next**.
10. Under **Review**, verify the settings. If you want to make changes, choose **Previous**. After confirming the Batch Operations settings, choose **Create job**.

For more information, see [Creating an S3 Batch Operations job](#).

Run your Batch Operations job

The setup wizard automatically returns you to the S3 Batch Operations section of the Amazon S3 console. Your new job transitions from the **New** state to the **Preparing** state as S3 begins the process. During the Preparing state, S3 reads the job's manifest, checks it for errors, and calculates the number of objects.

1. Choose the refresh button in the Amazon S3 console to check progress. Depending on the size of the manifest, reading can take minutes or hours.
2. After S3 finishes reading the job's manifest, the job moves to the **Awaiting your confirmation** state. Choose the option button to the left of the Job ID, and choose **Run job**.
3. Check the settings for the job, and choose **Run job** in the bottom-right corner.

After the job begins running, you can choose the refresh button to check progress through the console dashboard view or by selecting the specific job.

4. When the job is complete, you can view the **Successful** and **Failed** object counts to confirm that everything performed as expected. If you enabled job reports, check your job report for the exact cause of any failed operations.

You can also perform these steps by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information about tracking job status and completion reports, see [Tracking job status and completion reports](#).

Things to note

Consider the following issues when you use S3 Batch Operations to encrypt objects with S3 Bucket Keys:

- You will be charged for S3 Batch Operations jobs, objects, and requests in addition to any charges associated with the operation that S3 Batch Operations performs on your behalf, including data transfers, requests, and other charges. For more information, see [Amazon S3 pricing](#).
- If you use a versioned bucket, each S3 Batch Operations job performed creates new encrypted versions of your objects. It also maintains the previous versions without an S3 Bucket Key configured. To delete the old versions, set up an S3 Lifecycle expiration policy for noncurrent versions as described in [Lifecycle configuration elements](#).
- The copy operation creates new objects with new creation dates, which can affect lifecycle actions like archiving. If you copy all objects in your bucket, all the new copies have identical or similar creation dates. To further identify these objects and create different lifecycle rules for various data subsets, consider using object tags.

Summary

In this section, you sorted existing objects to filter out already encrypted data. Then you applied the S3 Bucket Key feature on unencrypted objects by using S3 Batch Operations to copy existing data to a bucket with an S3 Bucket Key activated. This process can save you time and money while allowing you to complete operations such as encrypting all existing objects.

For more information about S3 Batch Operations, see [Performing large-scale batch operations on Amazon S3 objects](#).

For examples that show the copy operation with tags using the AWS CLI and AWS SDK for Java, see [Creating a Batch Operations job with job tags used for labeling](#).

Invoke AWS Lambda function

The **Invoke AWS Lambda function** initiates AWS Lambda functions to perform custom actions on objects that are listed in a manifest. This section describes how to create a Lambda function to use with S3 Batch Operations and how to create a job to invoke the function. The S3 Batch Operations job uses the LambdaInvoke operation to run a Lambda function on every object listed in a manifest.

You can work with S3 Batch Operations for Lambda using the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST APIs. For more information about using Lambda, see [Getting Started with AWS Lambda](#) in the *AWS Lambda Developer Guide*.

The following sections explain how you can get started using S3 Batch Operations with Lambda.

Topics

- [Using Lambda with Amazon S3 batch operations](#)
- [Creating a Lambda function to use with S3 Batch Operations](#)
- [Creating an S3 Batch Operations job that invokes a Lambda function](#)
- [Providing task-level information in Lambda manifests](#)
- [Learning from S3 Batch Operations tutorial](#)

Using Lambda with Amazon S3 batch operations

When using S3 Batch Operations with AWS Lambda, you must create new Lambda functions specifically for use with S3 Batch Operations. You can't reuse existing Amazon S3 event-based functions with S3 Batch Operations. Event functions can only receive messages; they don't return messages. The Lambda functions that are used with S3 Batch Operations must accept and return messages. For more information about using Lambda with Amazon S3 events, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

You create an S3 Batch Operations job that invokes your Lambda function. The job runs the same Lambda function on all of the objects listed in your manifest. You can control what versions of your Lambda function to use while processing the objects in your manifest. S3 Batch Operations support unqualified Amazon Resource Names (ARNs), aliases, and specific versions. For more information, see [Introduction to AWS Lambda Versioning](#) in the *AWS Lambda Developer Guide*.

If you provide the S3 Batch Operations job with a function ARN that uses an alias or the \$LATEST qualifier, and you update the version that either of those points to, S3 Batch Operations starts calling the new version of your Lambda function. This can be useful when you want to update functionality part of the way through a large job. If you don't want S3 Batch Operations to change the version that is used, provide the specific version in the FunctionARN parameter when you create your job.

Using Lambda and Amazon S3 batch operations with directory buckets

Directory buckets are a type of Amazon S3 bucket that is designed for workloads or performance-critical applications that require consistent single-digit millisecond latency. For more information, see [Directory buckets](#).

There are special requirements for using Amazon S3 batch operations to invoke Lambda functions that act on directory buckets. For example, you must structure your Lambda request using an updated JSON schema, and specify [InvocationSchemaVersion 2.0](#) when you create the job. This updated schema allows you to specify optional key-value pairs for [UserArguments](#), which you can use to modify certain parameters of existing Lambda functions. For more information, see [Automate object processing in Amazon S3 directory buckets with S3 Batch Operations and AWS Lambda](#) in the *AWS Storage Blog*.

Response and result codes

There are two levels of codes that S3 Batch Operations expect from Lambda functions. The first is the response code for the entire request, and the second is a per-task result code. The following table contains the response codes.

Response code	Description
Succeeded	The task completed normally. If you requested a job completion report, the task's result string is included in the report.
TemporaryFailure	The task suffered a temporary failure and will be redriven before the job completes. The result string is ignored. If this is the final redrive, the error message is included in the final report.
PermanentFailure	The task suffered a permanent failure. If you requested a job-completion report, the task is marked as Failed and includes the error message string. Result strings from failed tasks are ignored.

Creating a Lambda function to use with S3 Batch Operations

This section provides example AWS Identity and Access Management (IAM) permissions that you must use with your Lambda function. It also contains an example Lambda function to use with S3 Batch Operations. If you have never created a Lambda function before, see [Tutorial: Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

You must create Lambda functions specifically for use with S3 Batch Operations. You can't reuse existing Amazon S3 event-based Lambda functions. This is because Lambda functions that are used for S3 Batch Operations must accept and return special data fields.

Important

AWS Lambda functions written in Java accept either [RequestHandler](#) or [RequestStreamHandler](#) handler interfaces. However, to support S3 Batch Operations request and response format, AWS Lambda requires the RequestStreamHandler interface for custom serialization and deserialization of a request and response.

This interface allows Lambda to pass an `InputStream` and `OutputStream` to the Java `handleRequest` method.

Be sure to use the RequestStreamHandler interface when using Lambda functions with S3 Batch Operations. If you use a RequestHandler interface, the batch job will fail with "Invalid JSON returned in Lambda payload" in the completion report.

For more information, see [Handler interfaces](#) in the *AWS Lambda User Guide*.

Example IAM permissions

The following are examples of the IAM permissions that are necessary to use a Lambda function with S3 Batch Operations.

Example — S3 Batch Operations trust policy

The following is an example of the trust policy that you can use for the Batch Operations IAM role. This IAM role is specified when you create the job and gives Batch Operations permission to assume the IAM role.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {
```

```
        "Effect": "Allow",
        "Principal": {
            "Service": "batchoperations.s3.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }
]
}
```

Example — Lambda IAM policy

The following is an example of an IAM policy that gives S3 Batch Operations permission to invoke the Lambda function and read the input manifest.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "BatchOperationsLambdaPolicy",
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion",
                "s3:PutObject",
                "lambda:InvokeFunction"
            ],
            "Resource": "*"
        }
    ]
}
```

Example request and response

This section provides request and response examples for the Lambda function.

Example Request

The following is a JSON example of a request for the Lambda function.

```
{
    "invocationSchemaVersion": "1.0",
    "invocationId": "YXNkbGZqYWRmaiBhc2RmdW9hZHNmZGpmaGFzbGtkaGZza2RmaAo",
    "job": {
```

```
        "id": "f3cc4f60-61f6-4a2b-8a21-d07600c373ce"
    },
    "tasks": [
        {
            "taskId": "dGFza2lkZ29lc2hlcmtUK",
            "s3Key": "customerImage1.jpg",
            "s3VersionId": "1",
            "s3BucketArn": "arn:aws:s3:us-east-1:0123456788:awsexamplebucket1"
        }
    ]
}
```

Example Response

The following is a JSON example of a response for the Lambda function.

```
{
    "invocationSchemaVersion": "1.0",
    "treatMissingKeysAs" : "PermanentFailure",
    "invocationId" : "YXNkbGZqYWVmBhc2RmdW9hZHNmZGpmaGFzbGtkaGZza2RmaAo",
    "results": [
        {
            "taskId": "dGFza2lkZ29lc2hlcmtUK",
            "resultCode": "Succeeded",
            "resultString": "[\"Mary Major\", \"John Stiles\"]"
        }
    ]
}
```

Example Lambda function for S3 Batch Operations

The following example Python Lambda removes a delete marker from a versioned object.

As the example shows, keys from S3 Batch Operations are URL encoded. To use Amazon S3 with other AWS services, it's important that you URL decode the key that is passed from S3 Batch Operations.

```
import logging
from urllib import parse
import boto3
from botocore.exceptions import ClientError

logger = logging.getLogger(__name__)
```

```
logger.setLevel("INFO")

s3 = boto3.client("s3")

def lambda_handler(event, context):
    """
    Removes a delete marker from the specified versioned object.

    :param event: The S3 batch event that contains the ID of the delete marker
                  to remove.
    :param context: Context about the event.
    :return: A result structure that Amazon S3 uses to interpret the result of the
            operation. When the result code is TemporaryFailure, S3 retries the
            operation.
    """
    # Parse job parameters from Amazon S3 batch operations
    invocation_id = event["invocationId"]
    invocation_schema_version = event["invocationSchemaVersion"]

    results = []
    result_code = None
    result_string = None

    task = event["tasks"][0]
    task_id = task["taskId"]

    try:
        obj_key = parse.unquote(task["s3Key"], encoding="utf-8")
        obj_version_id = task["s3VersionId"]
        bucket_name = task["s3BucketArn"].split(":")[-1]

        logger.info(
            "Got task: remove delete marker %s from object %s.", obj_version_id,
obj_key
        )

        try:
            # If this call does not raise an error, the object version is not a delete
            # marker and should not be deleted.
            response = s3.head_object(
                Bucket=bucket_name, Key=obj_key, VersionId=obj_version_id
            )
            result_code = "PermanentFailure"
        
```

```
        result_string = (
            f"Object {obj_key}, ID {obj_version_id} is not " f"a delete marker."
        )

        logger.debug(response)
        logger.warning(result_string)
    except ClientError as error:
        delete_marker = error.response["ResponseMetadata"]["HTTPHeaders"].get(
            "x-amz-delete-marker", "false"
        )
        if delete_marker == "true":
            logger.info(
                "Object %s, version %s is a delete marker.", obj_key,
obj_version_id
            )
        try:
            s3.delete_object(
                Bucket=bucket_name, Key=obj_key, VersionId=obj_version_id
            )
            result_code = "Succeeded"
            result_string = (
                f"Successfully removed delete marker "
                f"{obj_version_id} from object {obj_key}."
            )
            logger.info(result_string)
        except ClientError as error:
            # Mark request timeout as a temporary failure so it will be
retried.
            if error.response["Error"]["Code"] == "RequestTimeout":
                result_code = "TemporaryFailure"
                result_string = (
                    f"Attempt to remove delete marker from "
                    f"object {obj_key} timed out."
                )
                logger.info(result_string)
            else:
                raise
        else:
            raise ValueError(
                f"The x-amz-delete-marker header is either not "
                f"present or is not 'true'."
            )
    except Exception as error:
        # Mark all other exceptions as permanent failures.
```

```
        result_code = "PermanentFailure"
        result_string = str(error)
        logger.exception(error)
    finally:
        results.append(
            {
                "taskId": task_id,
                "resultCode": result_code,
                "resultString": result_string,
            }
        )
    return {
        "invocationSchemaVersion": invocation_schema_version,
        "treatMissingKeysAs": "PermanentFailure",
        "invocationId": invocation_id,
        "results": results,
    }
}
```

Creating an S3 Batch Operations job that invokes a Lambda function

When creating an S3 Batch Operations job to invoke a Lambda function, you must provide the following:

- The ARN of your Lambda function (which might include the function alias or a specific version number)
- An IAM role with permission to invoke the function
- The action parameter `LambdaInvokeFunction`

For more information about creating an S3 Batch Operations job, see [Creating an S3 Batch Operations job](#) and [Operations supported by S3 Batch Operations](#).

The following example creates an S3 Batch Operations job that invokes a Lambda function using the AWS CLI.

```
aws s3control create-job
--account-id <AccountID>
```

```
--operation '{"LambdaInvoke": { "FunctionArn":  
"arn:aws:lambda:Region:AccountID:function:LambdaFunctionName" } }'  
--manifest '{"Spec":{"Format":"S3BatchOperations_CSV_20180820","Fields":  
["Bucket","Key"]}}, "Location":  
{"ObjectArn":"arn:aws:s3:::ManifestLocation","ETag":"ManifestETag"}}'  
--report  
'{"Bucket":"arn:aws:s3:::awsexamplebucket1","Format":"Report_CSV_20180820","Enabled":true,"Pre"  
--priority 2  
--role-arn arn:aws:iam::AccountID:role/BatchOperationsRole  
--region Region  
--description "Lambda Function"
```

Providing task-level information in Lambda manifests

When you use AWS Lambda functions with S3 Batch Operations, you might want additional data to accompany each task/key that is operated on. For example, you might want to have both a source object key and new object key provided. Your Lambda function could then copy the source key to a new S3 bucket under a new name. By default, Amazon S3 batch operations let you specify only the destination bucket and a list of source keys in the input manifest to your job. The following describes how you can include additional data in your manifest so that you can run more complex Lambda functions.

To specify per-key parameters in your S3 Batch Operations manifest to use in your Lambda function's code, use the following URL-encoded JSON format. The key field is passed to your Lambda function as if it were an Amazon S3 object key. But it can be interpreted by the Lambda function to contain other values or multiple keys, as shown following.

Note

The maximum number of characters for the key field in the manifest is 1,024.

Example — manifest substituting the "Amazon S3 keys" with JSON strings

The URL-encoded version must be provided to S3 Batch Operations.

```
my-bucket,{"origKey": "object1key", "newKey": "newObject1Key"}  
my-bucket,{"origKey": "object2key", "newKey": "newObject2Key"}  
my-bucket,{"origKey": "object3key", "newKey": "newObject3Key"}
```

Example — manifest URL-encoded

This URL-encoded version must be provided to S3 Batch Operations. The non-URL-encoded version does not work.

```
my-bucket,%7B%22origKey%22%3A%20%22object1key%22%2C%20%22newKey%22%3A
%20%22newObject1Key%22%7D
my-bucket,%7B%22origKey%22%3A%20%22object2key%22%2C%20%22newKey%22%3A
%20%22newObject2Key%22%7D
my-bucket,%7B%22origKey%22%3A%20%22object3key%22%2C%20%22newKey%22%3A
%20%22newObject3Key%22%7D
```

Example — Lambda function with manifest format writing results to the job report

This Lambda function shows how to parse a pipe-delimited task that is encoded into the S3 Batch Operations manifest. The task indicates which revision operation is applied to the specified object.

```
import logging
from urllib import parse
import boto3
from botocore.exceptions import ClientError

logger = logging.getLogger(__name__)
logger.setLevel("INFO")

s3 = boto3.resource("s3")

def lambda_handler(event, context):
    """
    Applies the specified revision to the specified object.

    :param event: The Amazon S3 batch event that contains the ID of the object to
                  revise and the revision type to apply.
    :param context: Context about the event.
    :return: A result structure that Amazon S3 uses to interpret the result of the
            operation.
    """
    # Parse job parameters from Amazon S3 batch operations
    invocation_id = event["invocationId"]
    invocation_schema_version = event["invocationSchemaVersion"]

    results = []
```

```
result_code = None
result_string = None

task = event["tasks"][0]
task_id = task["taskId"]
# The revision type is packed with the object key as a pipe-delimited string.
obj_key, revision = parse.unquote(task["s3Key"], encoding="utf-8").split("|")
bucket_name = task["s3BucketArn"].split(":")[-1]

logger.info("Got task: apply revision %s to %s.", revision, obj_key)

try:
    stanza_obj = s3.Bucket(bucket_name).Object(obj_key)
    stanza = stanza_obj.get()["Body"].read().decode("utf-8")
    if revision == "lower":
        stanza = stanza.lower()
    elif revision == "upper":
        stanza = stanza.upper()
    elif revision == "reverse":
        stanza = stanza[::-1]
    elif revision == "delete":
        pass
    else:
        raise TypeError(f"Can't handle revision type '{revision}'.")

    if revision == "delete":
        stanza_obj.delete()
        result_string = f"Deleted stanza {stanza_obj.key}."
    else:
        stanza_obj.put(Body=bytes(stanza, "utf-8"))
        result_string = (
            f"Applied revision type '{revision}' to " f"stanza {stanza_obj.key}."
        )

    logger.info(result_string)
    result_code = "Succeeded"
except ClientError as error:
    if error.response["Error"]["Code"] == "NoSuchKey":
        result_code = "Succeeded"
        result_string = (
            f"Stanza {obj_key} not found, assuming it was deleted "
            f"in an earlier revision."
        )
    logger.info(result_string)
```

```
        else:
            result_code = "PermanentFailure"
            result_string = (
                f"Got exception when applying revision type '{revision}' "
                f"to {obj_key}: {error}."
            )
            logger.exception(result_string)
    finally:
        results.append(
            {
                "taskId": task_id,
                "resultCode": result_code,
                "resultString": result_string,
            }
        )
    return {
        "invocationSchemaVersion": invocation_schema_version,
        "treatMissingKeysAs": "PermanentFailure",
        "invocationId": invocation_id,
        "results": results,
    }
```

Learning from S3 Batch Operations tutorial

The following tutorial presents complete end-to-end procedures for some Batch Operations tasks with Lambda.

- [Tutorial: Batch-transcoding videos with S3 Batch Operations, AWS Lambda, and AWS Elemental MediaConvert](#)

Replace all object tags

The **Replace all object tags** operation replaces the Amazon S3 object tags on every object listed in the manifest. An Amazon S3 object tag is a key-value pair of strings that you can use to store metadata about an object.

To create a Replace all object tags job, you provide a set of tags that you want to apply. S3 Batch Operations applies the same set of tags to every object. The tag set that you provide replaces

whatever tag sets are already associated with the objects in the manifest. S3 Batch Operations does not support adding tags to objects while leaving the existing tags in place.

If the objects in your manifest are in a versioned bucket, you can apply the tag set to specific versions of every object. You do this by specifying a version ID for every object in the manifest. If you don't include a version ID for any object, then S3 Batch Operations applies the tag set to the latest version of every object.

Restrictions and limitations

- The AWS Identity and Access Management (IAM) role that you specify to run the Batch Operations job must have permissions to perform the underlying Amazon S3 Replace all object tags operation. For more information about the permissions required, see [PutObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.
- S3 Batch Operations uses the Amazon S3 [PutObjectTagging](#) operation to apply tags to each object in the manifest. All restrictions and limitations that apply to the underlying operation also apply to S3 Batch Operations jobs.

For more information about using the console to create jobs, see [Creating an S3 batch operations job](#).

For more information about object tagging, see [Categorizing your storage using tags](#) in this guide, and see [PutObjectTagging](#), [GetObjectTagging](#), and [DeleteObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.

Delete all object tags

The **Delete all object tags** operation removes all Amazon S3 object tag sets currently associated with the objects that are listed in the manifest. S3 Batch Operations does not support deleting tags from objects while keeping other tags in place.

If the objects in your manifest are in a versioned bucket, you can remove the tag sets from a specific version of an object. Do this by specifying a version ID for every object in the manifest. If you don't include a version ID for an object, S3 Batch Operations removes the tag set from the latest version of every object.

For more information about Batch Operations manifests, see [Specifying a manifest](#).

Warning

Running this job removes all object tag sets on every object listed in the manifest.

Restrictions and limitations

- The AWS Identity and Access Management (IAM) role that you specify to run the job must have permissions to perform the underlying Amazon S3 Delete object tagging operation. For more information, see [DeleteObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.
- S3 Batch Operations uses the Amazon S3 [DeleteObjectTagging](#) operation to remove the tag sets from every object in the manifest. All restrictions and limitations that apply to the underlying operation also apply to S3 Batch Operations jobs.

For more information about creating jobs, see [Creating an S3 Batch Operations job](#).

For more details about object tagging, see [Replace all object tags](#) in this guide, and [PutObjectTagging](#), [GetObjectTagging](#), and [DeleteObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.

Replace access control list

The **Replace access control list (ACL)** operation replaces the Amazon S3 access control lists (ACLs) for every object that is listed in the manifest. Using ACLs, you can define who can access an object and what actions they can perform.

S3 Batch Operations support custom ACLs that you define and canned ACLs that Amazon S3 provides with a predefined set of access permissions.

If the objects in your manifest are in a versioned bucket, you can apply the ACLs to specific versions of every object. You do this by specifying a version ID for every object in the manifest. If you don't include a version ID for any object, then S3 Batch Operations applies the ACL to the latest version of the object.

For more information about ACLs in Amazon S3, [Access control list \(ACL\) overview](#).

S3 Block Public Access

If you want to limit public access to all objects in a bucket, you should use Amazon S3 Block Public Access instead of S3 Batch Operations. Block Public Access can limit public access on a per-bucket

or account-wide basis with a single, simple operation that takes effect quickly. This makes it a better choice when your goal is to control public access to all objects in a bucket or account. Use S3 Batch Operations when you need to apply a customized ACL to every object in the manifest. For more information about S3 Block Public Access, see [Blocking public access to your Amazon S3 storage](#).

S3 Object Ownership

If the objects in the manifest are in a bucket that uses the bucket owner enforced setting for Object Ownership, the **Replace access control list (ACL)** operation can only specify object ACLs that grant full control to the bucket owner. The operation can't grant object ACL permissions to other AWS accounts or groups. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Restrictions and limitations

- The role that you specify to run the Replace access control list job must have permissions to perform the underlying Amazon S3 PutObjectAcl operation. For more information about the permissions required, see [PutObjectAcl](#) in the *Amazon Simple Storage Service API Reference*.
- S3 Batch Operations uses the Amazon S3 PutObjectAcl operation to apply the specified ACL to every object in the manifest. Therefore, all restrictions and limitations that apply to the underlying PutObjectAcl operation also apply to S3 Batch Operations Replace access control list jobs.

Restore objects with Batch Operations

The **Restore** operation initiates restore requests for the archived Amazon S3 objects that are listed in your manifest. The following archived objects must be restored before they can be accessed in real time:

- Objects archived in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes
- Objects archived through the S3 Intelligent-Tiering storage class in the Archive Access or Deep Archive Access tiers

Using an S3 Initiate Restore Object operation in your S3 Batch Operations job results in a restore request for every object that is specified in the manifest.

Important

The S3 Initiate Restore Object job only *initiates* the request to restore objects. S3 Batch Operations reports the job as complete for each object after the request is initiated for that object. Amazon S3 doesn't update the job or otherwise notify you when the objects have been restored. However, you can use S3 Event Notifications to receive notifications when the objects are available in Amazon S3. For more information, see [Amazon S3 Event Notifications](#).

When you create an S3 Initiate Restore Object job, the following arguments are available:

ExpirationInDays

This argument specifies how long the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive object remains available in Amazon S3. Initiate Restore Object jobs that target S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive objects require that you set `ExpirationInDays` to 1 or greater.

Important

Do not set `ExpirationInDays` when creating S3 Initiate Restore Object operation jobs that target S3 Intelligent-Tiering Archive Access and Deep Archive Access tier objects.

Objects in S3 Intelligent-Tiering archive access tiers are not subject to restore expiration, so specifying `ExpirationInDays` results in a restore request failure.

GlacierJobTier

Amazon S3 can restore objects by using one of three different retrieval tiers: EXPEDITED, STANDARD, and BULK. However, the S3 Batch Operations feature supports only the STANDARD and BULK retrieval tiers. For more information about the differences between the retrieval tiers, see [Archive retrieval options](#).

For more information about the pricing for each tier, see the **Requests & data retrievals** section on the [Amazon S3 pricing](#) page.

Differences when restoring from S3 Glacier and S3 Intelligent-Tiering

Restoring archived files from the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes differs from restoring files from the S3 Intelligent-Tiering storage class in the Archive Access or Deep Archive Access tiers.

- When you restore from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, a temporary *copy* of the object is created. Amazon S3 deletes this copy after the value that you specified in the `ExpirationInDays` argument has elapsed. After this temporary copy is deleted, you must submit an additional restore request to access the object.
- When restoring archived S3 Intelligent-Tiering objects, do *not* specify the `ExpirationInDays` argument. When you restore an object from the S3 Intelligent-Tiering Archive Access or Deep Archive Access tiers, the object transitions back into the S3 Intelligent-Tiering Frequent Access tier. After a minimum of 90 consecutive days of no access, the object automatically transitions into the Archive Access tier. After a minimum of 180 consecutive days of no access, the object automatically moves into the Deep Archive Access tier.
- Batch Operations jobs can operate either on S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage class objects *or* on S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tier objects. Batch Operations can't operate on both types of archived objects in the same job. To restore objects of both types, you *must* create separate Batch Operations jobs.

Overlapping restores

If your [S3 Initiate Restore Object](#) job tries to restore an object that is already in the process of being restored, S3 Batch Operations proceeds as follows.

The restore operation succeeds for the object if either of the following conditions is true:

- Compared to the restoration request already in progress, this job's `ExpirationInDays` value is the same and its `GlacierJobTier` value is faster.
- The previous restoration request has already been completed, and the object is currently available. In this case, Batch Operations updates the expiration date of the restored object to match the `ExpirationInDays` value that's specified in the in-progress restoration request.

The restore operation fails for the object if any of the following conditions are true:

- The restoration request already in progress has not yet been completed, and the restoration duration for this job (specified by the `ExpirationInDays` value) is different from the restoration duration that is specified in the in-progress restoration request.
- The restoration tier for this job (specified by the `GlacierJobTier` value) is the same or slower than the restoration tier that is specified in the in-progress restoration request.

Limitations

S3 Initiate Restore Object jobs have the following limitations:

- You must create the job in the same Region as the archived objects.
- S3 Batch Operations does not support the EXPEDITED retrieval tier.

For more information about restoring objects, see [Restoring an archived object](#).

S3 Object Lock retention

The **Object Lock** retention operation allows you to apply retention dates for your objects using either *governance* mode or *compliance* mode. These retention modes apply different levels of protection. You can apply either retention mode to any object version. Retention dates, like legal holds, prevent an object from being overwritten or deleted. Amazon S3 stores the *retain until date* specified in the object's metadata and protects the specified version of the object version until the retention period expires.

You can use S3 Batch Operations with Object Lock to manage retention dates of many Amazon S3 objects at once. You specify the list of target objects in your manifest and submit it to Batch Operations for completion. For more information, see S3 Object Lock [the section called "Retention periods"](#).

Your S3 Batch Operations job with retention dates runs *until completion, until cancellation, or until a failure state* is reached. You should use S3 Batch Operations and S3 Object Lock retention when you want to add, change, or remove the retention date for many objects with a single request.

Batch Operations verifies that Object Lock is enabled on your bucket before processing any keys in the manifest. To perform the operations and validation, Batch Operations needs `s3:GetBucketObjectLockConfiguration` and `s3:PutObjectRetention` permissions in an IAM role to allow Batch Operations to call Object Lock on your behalf. For more information, see [the section called "Object Lock considerations"](#).

For information about using this operation with the REST API, see [S3PutObjectRetention](#) in the [CreateJob](#) operation in the *Amazon Simple Storage Service API Reference*.

For an AWS Command Line Interface example of using this operation, see [the section called “Use Batch Operations with Object Lock retention”](#). For an AWS SDK for Java example, see [the section called “Use Batch Operations with Object Lock retention”](#).

Restrictions and limitations

- S3 Batch Operations does not make any bucket level changes.
- Versioning and S3 Object Lock must be configured on the bucket where the job is performed.
- All objects listed in the manifest must be in the same bucket.
- The operation works on the latest version of the object unless a version is explicitly specified in the manifest.
- You need `s3:PutObjectRetention` permission in your IAM role to use this.
- `s3:GetBucketObjectLockConfiguration` IAM permission is required to confirm that Object Lock is enabled for the S3 bucket.
- You can only extend the retention period of objects with COMPLIANCE mode retention dates applied, and it cannot be shortened.

S3 Object Lock legal hold

The **Object Lock legal hold** operation enables you to place a legal hold on an object version.

Like setting a retention period, a legal hold prevents an object version from being overwritten or deleted. However, a legal hold doesn't have an associated retention period and remains in effect until removed.

You can use S3 Batch Operations with Object Lock to add legal holds to *many* Amazon S3 objects at once. You can do this by listing the target objects in your manifest and submitting that list to Batch Operations. Your S3 Batch Operations job with Object Lock legal hold runs until completion, until cancellation, or until a failure state is reached.

S3 Batch Operations verifies that Object Lock is enabled on your S3 bucket before processing any keys in the manifest. To perform the object operations and bucket level validation, S3 Batch Operations needs `s3:PutObjectLegalHold` and `s3:GetBucketObjectLockConfiguration` in an IAM role allowing S3 Batch Operations to call S3 Object Lock on your behalf.

When you create the S3 Batch Operations job to remove the legal hold, you just need to specify *Off* as the legal hold status. For more information, see [the section called “Object Lock considerations”](#).

For information about how to use this operation with the REST API, see `S3PutObjectLegalHold` in the [CreateJob](#) operation in the *Amazon Simple Storage Service API Reference*.

For an example use of this operation, see [Using the AWS SDK for Java](#).

Restrictions and limitations

- S3 Batch Operations does not make any bucket level changes.
 - All objects listed in the manifest must be in the same bucket.
 - Versioning and S3 Object Lock must be configured on the bucket where the job is performed.
 - The operation works on the latest version of the object unless a version is explicitly specified in the manifest.
 - `s3:PutObjectLegalHold` permission is required in your IAM role to add or remove legal hold from objects.
 - `s3:GetBucketObjectLockConfiguration` IAM permission is required to confirm that S3 Object Lock is enabled for the S3 bucket.

Managing S3 Batch Operations jobs

Amazon S3 provides a robust set of tools to help you manage your S3 Batch Operations jobs after you create them. This section describes the operations that you can use to manage and track your jobs using the AWS Management Console, AWS CLI, AWS SDKs, or REST API.

Topics

- [Using the Amazon S3 console to manage your S3 Batch Operations jobs](#)
- [Listing jobs](#)
- [Viewing job details](#)
- [Assigning job priority](#)

Using the Amazon S3 console to manage your S3 Batch Operations jobs

Using the console, you can manage your S3 Batch Operations jobs. For example, you can:

- View active and queued jobs
- Change a job's priority
- Confirm and run a job
- Clone a job
- Cancel a job

To manage Batch Operations using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose the specific job that you would like to manage.

Listing jobs

You can retrieve a list of your S3 Batch Operations jobs. The list includes jobs that haven't yet finished and jobs that finished within the last 90 days. The job list includes information for each job, such as its ID, description, priority, current status, and the number of tasks that have succeeded and failed. You can filter your job list by status. When you retrieve a job list through the console, you can also search your jobs by description or ID and filter them by AWS Region.

Get a list of Active and Complete jobs

The following AWS CLI example gets a list of Active and Complete jobs.

```
aws s3control list-jobs \
    --region us-west-2 \
    --account-id acct-id \
    --job-statuses '["Active", "Complete"]' \
    --max-results 20
```

For more information and examples, see [list-jobs](#) in the *AWS CLI Command Reference*.

Viewing job details

If you want more information about a job than you can retrieve by listing jobs, you can view all of the details for a single job. You can view details for jobs that haven't yet finished or jobs that finished within the last 90 days. In addition to the information returned in a job list, a single job's details include other items, such as:

- The operation parameters
- Details about the manifest
- Information about the completion report (if you configured one when you created the job)
- The Amazon Resource Name (ARN) of the user role that you assigned to run the job

By viewing an individual job's details, you can access a job's entire configuration. To view a job's details, you can use the Amazon S3 console or the AWS Command Line Interface (AWS CLI).

Get an S3 Batch Operations job description in the Amazon S3 console

To view a Batch Operations job description by using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose the job ID of the specific job to view its details.

Get an S3 Batch Operations job description in the AWS CLI

The following example gets the description of an S3 Batch Operations job by using the AWS CLI. To use the following example command, replace the *user input placeholders* with your own information.

```
aws s3control describe-job \
--region us-west-2 \
--account-id acct-id \
--job-id 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c
```

For more information and examples, see [describe-job](#) in the *AWS CLI Command Reference*.

Assigning job priority

You can assign each job a numeric priority, which can be any positive integer. S3 Batch Operations prioritize jobs according to the assigned priority. Jobs with a higher priority (or a higher numeric value for the priority parameter) are evaluated first. Priority is determined in descending order. For example, a job queue with a priority value of 10 is given scheduling preference over a job queue with a priority value of 1.

You can change a job's priority while it is running. If you submit a new job with a higher priority while a job is running, the lower-priority job can pause to allow the higher-priority job to run.

Changing job priority does not affect job processing speed.

Note

S3 Batch Operations honor job priorities on a best-effort basis. Although jobs with higher priorities generally take precedence over jobs with lower priorities, Amazon S3 does not guarantee strict ordering of jobs.

Using the S3 console

How to update job priority in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Select the specific job that you would like to manage.
4. Choose **Action**. In the dropdown list, choose **Update priority**.

Using the AWS CLI

The following example updates the job priority using the AWS CLI. A higher number indicates a higher execution priority.

```
aws s3control update-job-priority \
--region us-west-2 \
--account-id acct-id \
--priority 98 \
--job-id 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c
```

Using the AWS SDK for Java

The following example updates the priority of an S3 Batch Operations job using the AWS SDK for Java.

For more information about job priority, see [Assigning job priority](#).

Example

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.UpdateJobPriorityRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class UpdateJobPriority {
    public static void main(String[] args) {
        String accountId = "Account ID";
        String jobId = "00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            UpdateJobPriorityRequest request = new UpdateJobPriorityRequest()
                .withAccountId(accountId)
                .withJobId(jobId)
                .withPriority(98);

            s3ControlClient.updateJobPriority(request);
        } catch (AmazonServiceException | SdkClientException e) {
            System.out.println("Error updating job priority: " + e.getMessage());
        }
    }
}
```

```
        .withRegion(US_WEST_2)
        .build();

    s3ControlClient.updateJobPriority(new UpdateJobPriorityRequest()
        .withAccountId(accountId)
        .withJobId(jobId)
        .withPriority(98));

} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Tracking job status and completion reports

With S3 Batch Operations, you can view and update job status, add notifications and logging, track job failures, and generate completion reports.

Job statuses

After you create and run a job, it progresses through a series of statuses. The following table describes the statuses and the possible transitions between them.

Status	Description	Transitions
New	A job begins in the New state when you create it.	A job automatically moves to the Preparing state when Amazon S3 begins processing the manifest object.
Preparing	Amazon S3 is processing the manifest object and other job parameters to set up and run the job.	A job automatically moves to the Ready state after Amazon S3 finishes processing the manifest and other parameters. It is then ready to begin running the specified operation on the objects listed in the manifest. If the job requires confirmation before running, such as when you create a job using the Amazon S3 console, then the job transitions from Preparing to Suspended. It remains in the Suspended state until you confirm that you want to run it.
Suspended	The job requires confirmation, but you have not yet confirmed that you want to run it. Only jobs that you create using the Amazon S3 console require confirmation. A job that is created using the console enters the Suspended state immediately after Preparing. After	After you confirm that you want to run the job, its status changes to Ready.

Status	Description	Transitions
	you confirm that you want to run the job and the job becomes Ready, it never returns to the Suspended state.	
Ready	Amazon S3 is ready to begin running the requested object operations.	A job automatically moves to Active when Amazon S3 begins to run it. The amount of time that a job remains in the Ready state depends on whether you have higher-priority jobs running already and how long those jobs take to complete.
Active	Amazon S3 is performing the requested operation on the objects listed in the manifest. While a job is Active, you can monitor its progress using the Amazon S3 console or the <code>DescribeJob</code> operation through the REST API, AWS CLI, or AWS SDKs.	A job moves out of the Active state when it is no longer running operations on objects. This can happen automatically, such as when a job completes successfully or fails. Or it can occur as a result of user actions, such as canceling a job. The state that the job moves to depends on the reason for the transition.
Pausing	The job is transitioning to Paused from another state.	A job automatically moves to Paused when the Pausing stage is finished.

Status	Description	Transitions
Paused	A job can become Paused if you submit another job with a higher priority while the current job is running.	A Paused job automatically returns to Active after any higher-priority jobs that are blocking the job's execution complete, fail, or are suspended.
Complete	The job has finished performing the requested operation on all objects in the manifest. The operation might have succeeded or failed for every object. If you configured the job to generate a completion report, the report is available as soon as the job is Complete.	Complete is a terminal state. Once a job reaches Complete, it does not transition to any other state.
Cancelling	The job is transitioning to the Cancelled state.	A job automatically moves to Cancelled when the Cancelling stage is finished.
Cancelled	You requested that the job be canceled, and S3 Batch Operations has successfully cancelled the job. The job will not submit any new requests to Amazon S3.	Cancelled is a terminal state. After a job reaches Cancelled, it will not transition to any other state.
Failing	The job is transitioning to the Failed state.	A job automatically moves to Failed once the Failing stage is finished.

Status	Description	Transitions
Failed	The job has failed and is no longer running. For more information about job failures, see Tracking job failure .	Failed is a terminal state. After a job reaches Failed, it will not transition to any other state.

Updating job status

The following AWS CLI and SDK for Java examples update the status of a Batch Operations job. For more information about using the S3 console to manage Batch Operations jobs, see [Using the Amazon S3 console to manage your S3 Batch Operations jobs](#).

Using the AWS CLI

- If you didn't specify the `--no-confirmation-required` parameter in the previous `create-job` example, the job remains in a suspended state until you confirm the job by setting its status to Ready. Amazon S3 then makes the job eligible for execution.

```
aws s3control update-job-status \
  --region us-west-2 \
  --account-id 181572960644 \
  --job-id 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c \
  --requested-job-status 'Ready'
```

- Cancel the job by setting the job status to Cancelled.

```
aws s3control update-job-status \
  --region us-west-2 \
  --account-id 181572960644 \
  --job-id 00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c \
  --status-update-reason "No longer needed" \
  --requested-job-status Cancelled
```

Using the AWS SDK for Java

The following example updates the status of an S3 Batch Operations job using the AWS SDK for Java.

For more information about job status, see [Tracking job status and completion reports](#).

Example

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.UpdateJobStatusRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class UpdateJobStatus {
    public static void main(String[] args) {
        String accountId = "Account ID";
        String jobId = "00e123a4-c0d8-41f4-a0eb-b46f9ba5b07c";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.updateJobStatus(new UpdateJobStatusRequest()
                .withAccountId(accountId)
                .withJobId(jobId)
                .withRequestedJobStatus("Ready"));

        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
        }
    }
}
```

```
// couldn't parse the response from Amazon S3.  
e.printStackTrace();  
}  
}  
}
```

Notifications and logging

In addition to requesting completion reports, you can also capture, review, and audit Batch Operations activity using AWS CloudTrail. Because Batch Operations use existing Amazon S3 APIs to perform tasks, those tasks also emit the same events that they would if you called them directly. Thus, you can track and record the progress of your job and all of its tasks using the same notification, logging, and auditing tools and processes that you already use with Amazon S3. For more information, see the examples in the following sections.

Note

Amazon S3 Batch Operations generates both management and data events in CloudTrail during job execution. The volume of these events scale with the number of keys in each job's manifest. Refer to the [CloudTrail pricing](#) page for details, which includes examples of how pricing changes depending on the number of trails you have configured in your account. To learn how to configure and log events to fit your needs, see [Create your first trail](#) in the *AWS CloudTrail User Guide*.

For more information about Amazon S3 events, see [Amazon S3 Event Notifications](#).

Tracking job failure

If an S3 Batch Operations job encounters a problem that prevents it from running successfully, such as not being able to read the specified manifest, the job fails. When a job fails, it generates one or more failure codes or failure reasons. S3 Batch Operations store the failure codes and reasons with the job so that you can view them by requesting the job's details. If you requested a completion report for the job, the failure codes and reasons also appear there.

To prevent jobs from running a large number of unsuccessful operations, Amazon S3 imposes a task-failure threshold on every Batch Operations job. When a job has run at least 1,000 tasks, Amazon S3 monitors the task failure rate. At any point, if the failure rate (the number of tasks that have failed as a proportion of the total number of tasks that have run) exceeds 50 percent, the job

fails. If your job fails because it exceeded the task-failure threshold, you can identify the cause of the failures. For example, you might have accidentally included some objects in the manifest that don't exist in the specified bucket. After fixing the errors, you can resubmit the job.

Note

S3 Batch Operations operate asynchronously and the tasks don't necessarily run in the order that the objects are listed in the manifest. Therefore, you can't use the manifest ordering to determine which objects' tasks succeeded and which ones failed. Instead, you can examine the job's completion report (if you requested one) or view your AWS CloudTrail event logs to help determine the source of the failures.

Completion reports

When you create a job, you can request a completion report. As long as S3 Batch Operations successfully invoke at least one task, Amazon S3 generates a completion report after it finishes running tasks, fails, or is canceled. You can configure the completion report to include all tasks or only failed tasks.

The completion report includes the job configuration and status and information for each task, including the object key and version, status, error codes, and descriptions of any errors. Completion reports provide an easy way to view the results of your tasks in a consolidated format with no additional setup required. For an example of a completion report, see [Examples: S3 Batch Operations completion reports](#).

If you don't configure a completion report, you can still monitor and audit your job and its tasks using CloudTrail and Amazon CloudWatch. For more information, see the following section.

Topics

- [Examples: Tracking an S3 Batch Operations job in Amazon EventBridge through AWS CloudTrail](#)
- [Examples: S3 Batch Operations completion reports](#)

Examples: Tracking an S3 Batch Operations job in Amazon EventBridge through AWS CloudTrail

Amazon S3 Batch Operations job activity is recorded as events in AWS CloudTrail. You can create a custom rule in Amazon EventBridge and send these events to the target notification resource of your choice, such as Amazon Simple Notification Service (Amazon SNS).

Note

Amazon EventBridge is the preferred way to manage your events. Amazon CloudWatch Events and EventBridge are the same underlying service and API, but EventBridge provides more features. Changes that you make in either CloudWatch or EventBridge appear in each console. For more information, see the [Amazon EventBridge User Guide](#).

Tracking Examples

- [S3 Batch Operations events recorded in CloudTrail](#)
- [EventBridge rule for tracking S3 Batch Operations job events](#)

S3 Batch Operations events recorded in CloudTrail

When a Batch Operations job is created, it is recorded as a JobCreated event in CloudTrail. As the job runs, it changes state during processing, and other JobStatusChanged events are recorded in CloudTrail. You can view these events on the [CloudTrail console](#). For more information about CloudTrail, see the [AWS CloudTrail User Guide](#).

Note

Only S3 Batch Operations job status-change events are recorded in CloudTrail.

Example S3 Batch Operations job completion event recorded by CloudTrail

```
{  
  "eventVersion": "1.05",  
  "userIdentity": {  
    "accountId": "123456789012",  
    "invokedBy": "s3.amazonaws.com"
```

```
},
"eventTime": "2020-02-05T18:25:30Z",
"eventSource": "s3.amazonaws.com",
"eventName": "JobStatusChanged",
"awsRegion": "us-west-2",
"sourceIPAddress": "s3.amazonaws.com",
"userAgent": "s3.amazonaws.com",
"requestParameters": null,
"responseElements": null,
"eventID": "f907577b-bf3d-4c53-b9ed-8a83a118a554",
"readOnly": false,
"eventType": "AwsServiceEvent",
"recipientAccountId": "123412341234",
"serviceEventDetails": {
    "jobId": "d6e58ec4-897a-4b6d-975f-10d7f0fb63ce",
    "jobArn": "arn:aws:s3:us-west-2:181572960644:job/d6e58ec4-897a-4b6d-975f-10d7f0fb63ce",
    "status": "Complete",
    "jobEventId": "b268784cf0a66749f1a05bce259804f5",
    "failureCodes": [],
    "statusChangeReason": []
}
}
```

EventBridge rule for tracking S3 Batch Operations job events

The following example shows how to create a rule in Amazon EventBridge to capture S3 Batch Operations events recorded by AWS CloudTrail to a target of your choice.

To do this, you create a rule by following all the steps in [Creating EventBridge rules that react to events](#). You paste the following S3 Batch Operations custom event pattern policy where applicable, and choose the target service of your choice.

S3 Batch Operations custom event pattern policy

```
{
    "source": [
        "aws.s3"
    ],
    "detail-type": [
        "AWS Service Event via CloudTrail"
    ],
    "detail": {
```

```
        "eventSource": [
            "s3.amazonaws.com"
        ],
        "eventName": [
            "JobCreated",
            "JobStatusChanged"
        ]
    }
}
```

The following examples are two Batch Operations events that were sent to Amazon Simple Queue Service (Amazon SQS) from an EventBridge event rule. A Batch Operations job goes through many different states while processing (New, Preparing, Active, etc.), so you can expect to receive several messages for each job.

Example JobCreated sample event

```
{  
  "version": "0",  
  "id": "51dc8145-541c-5518-2349-56d7dffdf2d8",  
  "detail-type": "AWS Service Event via CloudTrail",  
  "source": "aws.s3",  
  "account": "123456789012",  
  "time": "2020-02-27T15:25:49Z",  
  "region": "us-east-1",  
  "resources": [],  
  "detail": {  
    "eventVersion": "1.05",  
    "userIdentity": {  
      "accountId": "11112223334444",  
      "invokedBy": "s3.amazonaws.com"  
    },  
    "eventTime": "2020-02-27T15:25:49Z",  
    "eventSource": "s3.amazonaws.com",  
    "eventName": "JobCreated",  
    "awsRegion": "us-east-1",  
    "sourceIPAddress": "s3.amazonaws.com",  
    "userAgent": "s3.amazonaws.com",  
    "eventID": "7c38220f-f80b-4239-8b78-2ed867b7d3fa",  
    "readOnly": false,  
    "eventType": "AwsServiceEvent",  
    "serviceEventDetails": {
```

```
        "jobId": "e849b567-5232-44be-9a0c-40988f14e80c",
        "jobArn": "arn:aws:s3:us-east-1:181572960644:job/
e849b567-5232-44be-9a0c-40988f14e80c",
        "status": "New",
        "jobEventId": "f177ff24f1f097b69768e327038f30ac",
        "failureCodes": [],
        "statusChangeReason": []
    }
}
}
```

Example JobStatusChanged job completion event

```
{
  "version": "0",
  "id": "c8791abf-2af8-c754-0435-fd869ce25233",
  "detail-type": "AWS Service Event via CloudTrail",
  "source": "aws.s3",
  "account": "123456789012",
  "time": "2020-02-27T15:26:42Z",
  "region": "us-east-1",
  "resources": [],
  "detail": {
    "eventVersion": "1.05",
    "userIdentity": {
      "accountId": "1111222233334444",
      "invokedBy": "s3.amazonaws.com"
    },
    "eventTime": "2020-02-27T15:26:42Z",
    "eventSource": "s3.amazonaws.com",
    "eventName": "JobStatusChanged",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "s3.amazonaws.com",
    "userAgent": "s3.amazonaws.com",
    "eventID": "0238c1f7-c2b0-440b-8dbd-1ed5e5833afb",
    "readOnly": false,
    "eventType": "AwsServiceEvent",
    "serviceEventDetails": {
      "jobId": "e849b567-5232-44be-9a0c-40988f14e80c",
      "jobArn": "arn:aws:s3:us-east-1:181572960644:job/
e849b567-5232-44be-9a0c-40988f14e80c",
      "status": "Complete",
      "jobEventId": "51f5ac17dba408301d56cd1b2c8d1e9e",
    }
  }
}
```

```
        "failureCodes": [],
        "statusChangeReason": []
    }
}
}
```

Examples: S3 Batch Operations completion reports

When you create an S3 Batch Operations job, you can request a completion report for all tasks or just for failed tasks. As long as at least one task has been invoked successfully, S3 Batch Operations generates a report for jobs that have completed, failed, or been canceled.

The completion report contains additional information for each task, including the object key name and version, status, error codes, and descriptions of any errors. The description of errors for each failed task can be used to diagnose issues that occur during job creation, such as permissions.

Example top-level manifest result file

The top-level `manifest.json` file contains the locations of each succeeded report and (if the job had any failures) the location of failed reports, as shown in the following example.

```
{
    "Format": "Report_CSV_20180820",
    "ReportCreationDate": "2019-04-05T17:48:39.725Z",
    "Results": [
        {
            "TaskExecutionStatus": "succeeded",
            "Bucket": "my-job-reports",
            "MD5Checksum": "83b1c4cbe93fc893f54053697e10fd6e",
            "Key": "job-f8fb9d89-a3aa-461d-bddc-ea6a1b131955/
results/6217b0fab0de85c408b4be96aeaca9b195a7daa5.csv"
        },
        {
            "TaskExecutionStatus": "failed",
            "Bucket": "my-job-reports",
            "MD5Checksum": "22ee037f3515975f7719699e5c416eaa",
            "Key": "job-f8fb9d89-a3aa-461d-bddc-ea6a1b131955/results/
b2ddad417e94331e9f37b44f1faf8c7ed5873f2e.csv"
        }
    ],
    "ReportSchema": "Bucket, Key, VersionId, TaskStatus, ErrorCode, HTTPStatusCode,
ResultMessage"
```

{}

Example failed tasks reports

Failed tasks reports contain the following information for all *failed* tasks:

- Bucket
- Key
- VersionId
- TaskStatus
- ErrorCode
- HTTPStatusCode
- ResultMessage

The following example report shows a case in which the AWS Lambda function timed out, causing failures to exceed the failure threshold. It was then marked as a PermanentFailure.

```
awsexamplebucket1,image_14975,,failed,200,PermanentFailure,"Lambda returned
function error: {""errorMessage"":""2019-04-05T17:35:21.155Z 2845ca0d-38d9-4c4b-

```

Example succeeded tasks report

Succeeded tasks reports contain the following for the *completed* tasks:

- Bucket
- Key
- VersionId
- TaskStatus
- ErrorCode
- HTTPStatusCode
- ResultMessage

In the following example, the Lambda function successfully copied the Amazon S3 object to another bucket. The returned Amazon S3 response is passed back to S3 Batch Operations and is then written into the final completion report.

```
awsexamplebucket1,image_17775,,succeeded,200,,"{u'CopySourceVersionId':  
    'xVR78haVK1RnurYofbTfYr3ufYbktF8h', u'CopyObjectResult': {u'LastModified':

Controlling access and labeling jobs using tags

You can label and control access to your S3 Batch Operations jobs by adding *tags*. Tags can be used to identify who is responsible for a Batch Operations job. The presence of job tags can grant or limit a user's ability to cancel a job, activate a job in the confirmation state, or change a job's priority level. You can create jobs with tags attached to them, and you can add tags to jobs after they are created. Each tag is a key-value pair that can be included when you create the job or updated later.

Warning

Job tags should not contain any confidential information or personal data.

Consider the following tagging example: Suppose that you want your Finance department to create a Batch Operations job. You could write an AWS Identity and Access Management (IAM) policy that allows a user to invoke `CreateJob`, provided that the job is created with the `Department` tag assigned the value `Finance`. Furthermore, you could attach that policy to all users who are members of the Finance department.

Continuing with this example, you could write a policy that allows a user to update the priority of any job that has the desired tags, or cancel any job that has those tags. For more information, see [the section called “Controlling permissions”](#).

You can add tags to new S3 Batch Operations jobs when you create them, or you can add them to existing jobs.

Note the following tag restrictions:

- You can associate up to 50 tags with a job as long as they have unique tag keys.

- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length.
- The key and values are case sensitive.

For more information about tag restrictions, see [User-Defined Tag Restrictions](#) in the *AWS Billing and Cost Management User Guide*.

API operations related to S3 Batch Operations job tagging

Amazon S3 supports the following API operations that are specific to S3 Batch Operations job tagging:

- [GetJobTagging](#) — Returns the tag set associated with a Batch Operations job.
- [PutJobTagging](#) — Replaces the tag set associated with a job. There are two distinct scenarios for S3 Batch Operations job tag management using this API action:
 - Job has no tags — You can add a set of tags to a job (the job has no prior tags).
 - Job has a set of existing tags — To modify the existing tag set, you can either replace the existing tag set entirely, or make changes within the existing tag set by retrieving the existing tag set using [GetJobTagging](#), modify that tag set, and use this API action to replace the tag set with the one you have modified.

 **Note**

If you send this request with an empty tag set, S3 Batch Operations deletes the existing tag set on the object. If you use this method, you are charged for a Tier 1 Request (PUT). For more information, see [Amazon S3 pricing](#).

To delete existing tags for your Batch Operations job, the `DeleteJobTagging` action is preferred because it achieves the same result without incurring charges.

- [DeleteJobTagging](#) — Deletes the tag set associated with a Batch Operations job.

Creating a Batch Operations job with job tags used for labeling

You can label and control access to your S3 Batch Operations jobs by adding *tags*. Tags can be used to identify who is responsible for a Batch Operations job. You can create jobs with tags attached to them, and you can add tags to jobs after they are created. For more information, see [the section called “Using tags”](#).

Using the AWS CLI

The following AWS CLI example creates an S3 Batch Operations S3PutObjectCopy job using job tags as labels for the job.

1. Select the action or OPERATION that you want the Batch Operations job to perform, and choose your TargetResource.

```
read -d '' OPERATION <<EOF
{
    "S3PutObjectCopy": {
        "TargetResource": "arn:aws:s3:::destination-bucket"
    }
}
EOF
```

2. Identify the job TAGS that you want for the job. In this case, you apply two tags, department and FiscalYear, with the values Marketing and 2020 respectively.

```
read -d '' TAGS <<EOF
[
    {
        "Key": "department",
        "Value": "Marketing"
    },
    {
        "Key": "FiscalYear",
        "Value": "2020"
    }
]
EOF
```

3. Specify the MANIFEST for the Batch Operations job.

```
read -d '' MANIFEST <<EOF
{
    "Spec": {
        "Format": "EXAMPLE_S3BatchOperations_CSV_20180820",
        "Fields": [
            "Bucket",
            "Key"
        ]
    },
}
```

```
"Location": {  
    "ObjectArn": "arn:aws:s3:::example-bucket/example_manifest.csv",  
    "ETag": "example-5dc7a8bfb90808fc5d546218"  
}  
}  
EOF
```

4. Configure the REPORT for the Batch Operations job.

```
read -d '' REPORT <<EOF  
{  
    "Bucket": "arn:aws:s3:::example-report-bucket",  
    "Format": "Example_Report_CSV_20180820",  
    "Enabled": true,  
    "Prefix": "reports/copy-with-replace-metadata",  
    "ReportScope": "AllTasks"  
}  
EOF
```

5. Run the create-job action to create your Batch Operations job with inputs set in the preceding steps.

```
aws \  
    s3control create-job \  
    --account-id 123456789012 \  
    --manifest "${MANIFEST//$/\n}" \  
    --operation "${OPERATION//$/\n/}" \  
    --report "${REPORT//$/\n}" \  
    --priority 10 \  
    --role-arn arn:aws:iam::123456789012:role/batch-operations-role \  
    --tags "${TAGS//$/\n/}" \  
    --client-request-token "$(uuidgen)" \  
    --region us-west-2 \  
    --description "Copy with Replace Metadata";
```

Using the AWS SDK for Java

Example

The following example creates an S3 Batch Operations job with tags using the AWS SDK for Java.

```
public String createJob(final AWSS3ControlClient awss3ControlClient) {
```

```
final String manifestObjectArn = "arn:aws:s3:::example-manifest-bucket/  
manifests/10_manifest.csv";  
final String manifestObjectVersionId = "example-5dc7a8bfb90808fc5d546218";  
  
final JobManifestLocation manifestLocation = new JobManifestLocation()  
    .withObjectArn(manifestObjectArn)  
    .withETag(manifestObjectVersionId);  
  
final JobManifestSpec manifestSpec =  
    new  
JobManifestSpec().withFormat(JobManifestFormat.S3InventoryReport_CSV_20161130);  
  
final JobManifest manifestToPublicApi = new JobManifest()  
    .withLocation(manifestLocation)  
    .withSpec(manifestSpec);  
  
final String jobReportBucketArn = "arn:aws:s3:::example-report-bucket";  
final String jobReportPrefix = "example-job-reports";  
  
final JobReport jobReport = new JobReport()  
    .withEnabled(true)  
    .withReportScope(JobReportScope.AllTasks)  
    .withBucket(jobReportBucketArn)  
    .withPrefix(jobReportPrefix)  
    .withFormat(JobReportFormat.Report_CSV_20180820);  
  
final String lambdaFunctionArn = "arn:aws:lambda:us-  
west-2:123456789012:function:example-function";  
  
final JobOperation jobOperation = new JobOperation()  
    .withLambdaInvoke(new  
LambdaInvokeOperation().withFunctionArn(lambdaFunctionArn));  
  
final S3Tag departmentTag = new  
S3Tag().withKey("department").withValue("Marketing");  
final S3Tag fiscalYearTag = new S3Tag().withKey("FiscalYear").withValue("2020");  
  
final String roleArn = "arn:aws:iam::123456789012:role/example-batch-operations-  
role";  
final Boolean requiresConfirmation = true;  
final int priority = 10;  
  
final CreateJobRequest request = new CreateJobRequest()  
    .withAccountId("123456789012")
```

```
.withDescription("Test lambda job")
.withManifest(manifestToPublicApi)
.withOperation(jobOperation)
.withPriority(priority)
.withRoleArn(roleArn)
.withReport(jobReport)
.withTags(departmentTag, fiscalYearTag)
.withConfirmationRequired(requiresConfirmation);

final CreateJobResult result = awss3ControlClient.createJob(request);

return result.getJobId();
}
```

Deleting the tags from an S3 Batch Operations job

You can use these examples to delete the tags from a Batch Operations job.

Using the AWS CLI

The following example deletes the tags from a Batch Operations job using the AWS CLI.

```
aws \
s3control delete-job-tagging \
--account-id 123456789012 \
--job-id Example-e25a-4ed2-8bee-7f8ed7fc2f1c \
--region us-east-1;
```

Delete the job tags of a Batch Operations job

Example

The following example deletes the tags of an S3 Batch Operations job using the AWS SDK for Java.

```
public void deleteJobTagging(final AWSS3ControlClient awss3ControlClient,
                             final String jobId) {
    final DeleteJobTaggingRequest deleteJobTaggingRequest = new
DeleteJobTaggingRequest()
    .withJobId(jobId);

    final DeleteJobTaggingResult deleteJobTaggingResult =
        awss3ControlClient.deleteJobTagging(deleteJobTaggingRequest);
```

{

Putting job tags for an existing S3 Batch Operations job

You can use [PutJobTagging](#) to add job tags to your existing S3 Batch Operations jobs. For more information, see the following examples.

Using the AWS CLI

The following is an example of using `s3control put-job-tagging` to add job tags to your S3 Batch Operations job using the AWS CLI.

Note

If you send this request with an empty tag set, S3 Batch Operations deletes the existing tag set on the object. Also, if you use this method, you are charged for a Tier 1 Request (PUT).

For more information, see [Amazon S3 pricing](#).

To delete existing tags for your Batch Operations job, the `DeleteJobTagging` action is preferred because it achieves the same result without incurring charges.

1. Identify the job TAGS that you want for the job. In this case, you apply two tags, `department` and `FiscalYear`, with the values `Marketing` and `2020` respectively.

```
read -d '' TAGS <<EOF
[
  {
    "Key": "department",
    "Value": "Marketing"
  },
  {
    "Key": "FiscalYear",
    "Value": "2020"
  }
]
EOF
```

2. Run the `put-job-tagging` action with the required parameters.

```
aws \
```

```
s3control put-job-tagging \
--account-id 123456789012 \
--tags "${TAGS//$/'\n'/" \
--job-id Example-e25a-4ed2-8bee-7f8ed7fc2f1c \
--region us-east-1;
```

Using the AWS SDK for Java

Example

The following example puts the tags of an S3 Batch Operations job using the AWS SDK for Java.

```
public void putJobTagging(final AWSS3ControlClient awss3ControlClient,
                           final String jobId) {
    final S3Tag departmentTag = new
    S3Tag().withKey("department").withValue("Marketing");
    final S3Tag fiscalYearTag = new S3Tag().withKey("FiscalYear").withValue("2020");

    final PutJobTaggingRequest putJobTaggingRequest = new PutJobTaggingRequest()
        .withJobId(jobId)
        .withTags(departmentTag, fiscalYearTag);

    final PutJobTaggingResult putJobTaggingResult =
    awss3ControlClient.putJobTagging(putJobTaggingRequest);
}
```

Getting the tags of a S3 Batch Operations job

You can use `GetJobTagging` to return the tags of an S3 Batch Operations job. For more information, see the following examples.

Using the AWS CLI

The following example gets the tags of a Batch Operations job using the AWS CLI.

```
aws \
s3control get-job-tagging \
--account-id 123456789012 \
--job-id Example-e25a-4ed2-8bee-7f8ed7fc2f1c \
--region us-east-1;
```

Using the AWS SDK for Java

Example

The following example gets the tags of an S3 Batch Operations job using the AWS SDK for Java.

```
public List<S3Tag> getJobTagging(final AWSS3ControlClient awss3ControlClient,
                                  final String jobId) {
    final GetJobTaggingRequest getJobTaggingRequest = new GetJobTaggingRequest()
        .withJobId(jobId);

    final GetJobTaggingResult getJobTaggingResult =
        awss3ControlClient.getJobTagging(getJobTaggingRequest);

    final List<S3Tag> tags = getJobTaggingResult.getTags();

    return tags;
}
```

Controlling permissions for S3 Batch Operations using job tags

To help you manage your S3 Batch Operations jobs, you can add *job tags*. With job tags, you can control access to your Batch Operations jobs and enforce that tags be applied when any job is created.

You can apply up to 50 job tags to each Batch Operations job. This allows you to set very granular policies restricting the set of users that can edit the job. Job tags can grant or limit a user's ability to cancel a job, activate a job in the confirmation state, or change a job's priority level. In addition, you can enforce that tags be applied to all new jobs, and specify the allowed key-value pairs for the tags. You can express all of these conditions using the same [IAM policy language](#). For more information, see [Actions, resources, and condition keys for Amazon S3](#).

The following example shows how you can use S3 Batch Operations job tags to grant users permission to create and edit only the jobs that are run within a specific *department* (for example, the *Finance* or *Compliance* department). You can also assign jobs based on the stage of *development* that they are related to, such as *QA* or *Production*.

In this example, you use S3 Batch Operations job tags in AWS Identity and Access Management (IAM) policies to grant users permission to create and edit only the jobs being run within their

department. You assign jobs based on the stage of development that they are related to, such as *QA* or *Production*.

This example uses the following departments, with each using Batch Operations in different ways:

- Finance
- Compliance
- Business Intelligence
- Engineering

Topics

- [Controlling access by assigning tags to users and resources](#)
- [Tagging Batch Operations jobs by stage and enforcing limits on job priority](#)

Controlling access by assigning tags to users and resources

In this scenario, the administrators are using [attribute-based access control \(ABAC\)](#). ABAC is an IAM authorization strategy that defines permissions by attaching tags to both users and AWS resources.

Users and jobs are assigned one of the following department tags:

Key : Value

- department : Finance
- department : Compliance
- department : BusinessIntelligence
- department : Engineering

 **Note**

Job tag keys and values are case sensitive.

Using the ABAC access control strategy, you grant a user in the Finance department permission to create and manage S3 Batch Operations jobs within their department by associating the tag `department=Finance` with their user.

Furthermore, you can attach a managed policy to the IAM user that allows any user in their company to create or modify S3 Batch Operations jobs within their respective departments.

The policy in this example includes three policy statements:

- The first statement in the policy allows the user to create a Batch Operations job provided that the job creation request includes a job tag that matches their respective department. This is expressed using the "\${aws:PrincipalTag/department}" syntax, which is replaced by the user's department tag at policy evaluation time. The condition is satisfied when the value provided for the department tag in the request ("aws:RequestTag/department") matches the user's department.
- The second statement in the policy allows users to change the priority of jobs or update a job's status provided that the job the user is updating matches the user's department.
- The third statement allows a user to update a Batch Operations job's tags at any time via a PutJobTagging request as long as (1) their department tag is preserved and (2) the job they're updating is within their department.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3:CreateJob",  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:RequestTag/department": "${aws:PrincipalTag/  
department}"  
                }  
            }  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:UpdateJobPriority",  
                "s3:UpdateJobStatus"  
            ],  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:RequestTag/department": "${aws:PrincipalTag/  
department}"  
                }  
            }  
        }  
    ]  
}
```

```
        "aws:ResourceTag/department": "${aws:PrincipalTag/department}"  
    }  
},  
{  
    "Effect": "Allow",  
    "Action": "s3:PutJobTagging",  
    "Resource": "*",  
    "Condition": {  
        "StringEquals": {  
            "aws:RequestTag/department": "${aws:PrincipalTag/department}",  
            "aws:ResourceTag/department": "${aws:PrincipalTag/department}"  
        }  
    }  
}  
]  
}
```

Tagging Batch Operations jobs by stage and enforcing limits on job priority

All S3 Batch Operations jobs have a numeric priority, which Amazon S3 uses to decide in what order to run the jobs. For this example, you restrict the maximum priority that most users can assign to jobs, with higher priority ranges reserved for a limited set of privileged users, as follows:

- QA stage priority range (low): 1-100
- Production stage priority range (high): 1-300

To do this, introduce a new tag set representing the *stage* of the job:

Key : Value

- stage : QA
- stage : Production

Creating and updating low-priority jobs within a department

This policy introduces two new restrictions on S3 Batch Operations job creation and update, in addition to the department-based restriction:

- It allows users to create or update jobs in their department with a new condition that requires the job to include the tag stage=QA.
- It allows users to create or update a job's priority up to a new maximum priority of 100.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3:CreateJob",  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:RequestTag/department": "${aws:PrincipalTag/department}",  
                    "aws:RequestTag/stage": "QA"  
                },  
                "NumericLessThanEquals": {  
                    "s3:RequestJobPriority": 100  
                }  
            }  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:UpdateJobStatus"  
            ],  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:ResourceTag/department": "${aws:PrincipalTag/department}"  
                }  
            }  
        },  
        {  
            "Effect": "Allow",  
            "Action": "s3:UpdateJobPriority",  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:RequestJobPriority": 100  
                }  
            }  
        }  
    ]  
}
```

```
        "aws:ResourceTag/department": "${aws:PrincipalTag/department}",
        "aws:ResourceTag/stage": "QA"
    },
    "NumericLessThanEquals": {
        "s3:RequestJobPriority": 100
    }
}
},
{
    "Effect": "Allow",
    "Action": "s3:PutJobTagging",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:RequestTag/department" : "${aws:PrincipalTag/department}",
            "aws:ResourceTag/department": "${aws:PrincipalTag/department}",
            "aws:RequestTag/stage": "QA",
            "aws:ResourceTag/stage": "QA"
        }
    }
},
{
    "Effect": "Allow",
    "Action": "s3:GetJobTagging",
    "Resource": "*"
}
]
}
```

Creating and updating high-priority jobs within a department

A small number of users might require the ability to create high priority jobs in either *QA* or *Production*. To support this need, you create a managed policy that's adapted from the low-priority policy in the previous section.

This policy does the following:

- Allows users to create or update jobs in their department with either the tag `stage=QA` or `stage=Production`.
- Allows users to create or update a job's priority up to a maximum of 300.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3:CreateJob",  
            "Resource": "*",  
            "Condition": {  
                "ForAnyValue:StringEquals": {  
                    "aws:RequestTag/stage": [  
                        "QA",  
                        "Production"  
                    ]  
                },  
                "StringEquals": {

    }
}
]
```

Managing S3 Object Lock using S3 Batch Operations

With S3 Object Lock, you can place a legal hold on an object version. Like setting a retention period, a legal hold prevents an object version from being overwritten or deleted. However, a legal

hold doesn't have an associated retention period and remains in effect until removed. For more information, see [S3 Object Lock legal hold](#).

For information about using S3 Batch Operations with Object Lock to add legal holds to *many* Amazon S3 objects at once, see the following sections.

Topics

- [Enabling S3 Object Lock using S3 Batch Operations](#)
- [Setting Object Lock retention using Batch Operations](#)
- [Using S3 Batch Operations with S3 Object Lock retention compliance mode](#)
- [Use S3 Batch Operations with S3 Object Lock retention governance mode](#)
- [Using S3 Batch Operations to turn off S3 Object Lock legal hold](#)

Enabling S3 Object Lock using S3 Batch Operations

You can use S3 Batch Operations with S3 Object Lock to manage retention or enable a legal hold for many Amazon S3 objects at once. You specify the list of target objects in your manifest and submit it to Batch Operations for completion. For more information, see [the section called "Object Lock retention"](#) and [the section called "Object Lock legal hold"](#).

The following examples show how to create an IAM role with S3 Batch Operations permissions and update the role permissions to create jobs that enable Object Lock. In the examples, replace any variable values with those that suit your needs. You must also have a CSV manifest identifying the objects for your S3 Batch Operations job. For more information, see [the section called "Specifying a manifest"](#).

Using the AWS CLI

1. Create an IAM role and assign S3 Batch Operations permissions to run.

This step is required for all S3 Batch Operations jobs.

```
export AWS_PROFILE='aws-user'

read -d '' bops_trust_policy <<EOF
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": "s3:BatchGetObject"
        }
    ]
}
```

```
"Effect": "Allow",
"Principal": {
    "Service": [
        "batchoperations.s3.amazonaws.com"
    ]
},
"Action": "sts:AssumeRole"
}
]
}
EOF
aws iam create-role --role-name bops-objectlock --assume-role-policy-document
"${bops_trust_policy}"
```

2. Set up S3 Batch Operations with S3 Object Lock to run.

In this step, you allow the role to do the following:

- Run Object Lock on the S3 bucket that contains the target objects that you want Batch Operations to run on.
- Read the S3 bucket where the manifest CSV file and the objects are located.
- Write the results of the S3 Batch Operations job to the reporting bucket.

```
read -d '' bops_permissions <<EOF
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:GetBucketObjectLockConfiguration",
            "Resource": [
                "arn:aws:s3:::{ManifestBucket}"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::{ManifestBucket}"
            ]
        }
    ]
}
EOF
```

```
        "arn:aws:s3:::{ManifestBucket}}/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation"
    ],
    "Resource": [
        "arn:aws:s3:::{ReportBucket}}/*"
    ]
}
]
}
EOF

aws iam put-role-policy --role-name bops-objectlock --policy-name object-lock-permissions --policy-document "${bops_permissions}"
```

Using the AWS SDK for Java

The following examples show how to create an IAM role with S3 Batch Operations permissions, and update the role permissions to create jobs that enable object lock using the AWS SDK for Java. In the code, replace any variable values with those that suit your needs. You must also have a CSV manifest identifying the objects for your S3 Batch Operations job. For more information, see [the section called "Specifying a manifest".](#)

You perform the following steps:

1. Create an IAM role and assign S3 Batch Operations permissions to run. This step is required for all S3 Batch Operations jobs.
2. Set up S3 Batch Operations with S3 Object Lock to run.

You allow the role to do the following:

1. Run Object Lock on the S3 bucket that contains the target objects that you want Batch Operations to run on.
2. Read the S3 bucket where the manifest CSV file and the objects are located.
3. Write the results of the S3 Batch Operations job to the reporting bucket.

```
public void createObjectLockRole() {
    final String roleName = "bops-object-lock";

    final String trustPolicy = "{" +
        "  \"Version\": \"2012-10-17\", " +
        "  \"Statement\": [ " +
        "    { " +
        "      \"Effect\": \"Allow\", " +
        "      \"Principal\": { " +
        "        \"Service\": [ " +
        "          \"batchoperations.s3.amazonaws.com\" " +
        "        ]" +
        "      }, " +
        "      \"Action\": \"sts:AssumeRole\" " +
        "    } " +
        "  ]" +
    "}";

    final String bopsPermissions = "{" +
        "  \"Version\": \"2012-10-17\", " +
        "  \"Statement\": [ " +
        "    { " +
        "      \"Effect\": \"Allow\", " +
        "      \"Action\": \"s3:GetBucketObjectLockConfiguration\", " +
        "      \"Resource\": [ " +
        "        \"arn:aws:s3:::ManifestBucket\" " +
        "      ]" +
        "    }, " +
        "    { " +
        "      \"Effect\": \"Allow\", " +
        "      \"Action\": [ " +
        "        \"s3:GetObject\", " +
        "        \"s3:GetObjectVersion\", " +
        "        \"s3:GetBucketLocation\" " +
        "      ], " +
        "      \"Resource\": [ " +
        "        \"arn:aws:s3:::ManifestBucket/*\" " +
        "      ]" +
        "    }, " +
        "    { " +
        "      \"Effect\": \"Allow\", " +
        "      \"Action\": [ " +
        "        \"s3:PutObject\" " +
    "      ]" +
    "  ]" +
}
```

```
"           \"s3:GetBucketLocation\\"" +
"           ]," +
"           \"Resource\": [\" +
"               \"arn:aws:s3:::ReportBucket/*\\"", +
"           ]" +
"       }" +
"   ]" +
"}";
```

```
final AmazonIdentityManagement iam =
    AmazonIdentityManagementClientBuilder.defaultClient();

final CreateRoleRequest createRoleRequest = new CreateRoleRequest()
    .withAssumeRolePolicyDocument(bopsPermissions)
    .withRoleName(roleName);

final CreateRoleResult createRoleResult = iam.createRole(createRoleRequest);

final PutRolePolicyRequest putRolePolicyRequest = new PutRolePolicyRequest()
    .withPolicyDocument(bopsPermissions)
    .withPolicyName("bops-permissions")
    .withRoleName(roleName);

final PutRolePolicyResult putRolePolicyResult =
iam.putRolePolicy(putRolePolicyRequest);
}
```

Setting Object Lock retention using Batch Operations

The following example allows the rule to set S3 Object Lock retention for your objects in the manifest bucket.

You update the role to include s3:PutObjectRetention permissions so that you can run Object Lock retention on the objects in your bucket.

Using the AWS CLI

```
export AWS_PROFILE='aws-user'

read -d '' retention_permissions <<EOF
{
    "Version": "2012-10-17",
    "Statement": [
```

```
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:PutObjectRetention"  
    ],  
    "Resource": [  
        "arn:aws:s3:::{ManifestBucket}/*"  
    ]  
}  
]  
}  
EOF
```

```
aws iam put-role-policy --role-name bops-objectlock --policy-name retention-permissions  
--policy-document "${retention_permissions}"
```

Using the AWS SDK for Java

```
public void allowPutObjectRetention() {  
    final String roleName = "bops-object-lock";  
  
    final String retentionPermissions = "{" +  
        "    \"Version\": \"2012-10-17\", " +  
        "    \"Statement\": [" +  
        "        {" +  
        "            \"Effect\": \"Allow\", " +  
        "            \"Action\": [" +  
        "                \"s3:PutObjectRetention\" " +  
        "            ], " +  
        "            \"Resource\": [" +  
        "                \"arn:aws:s3:::ManifestBucket*\" " +  
        "            ] " +  
        "        } " +  
        "    ] " +  
    "};  
  
    final AmazonIdentityManagement iam =  
        AmazonIdentityManagementClientBuilder.defaultClient();  
  
    final PutRolePolicyRequest putRolePolicyRequest = new PutRolePolicyRequest()  
        .withPolicyDocument(retentionPermissions)  
        .withPolicyName("retention-permissions")  
        .withRoleName(roleName);
```

```
    final PutRolePolicyResult putRolePolicyResult =
iam.putRolePolicy(putRolePolicyRequest);
}
```

Using S3 Batch Operations with S3 Object Lock retention compliance mode

The following example builds on the previous examples of creating a trust policy and setting S3 Batch Operations and S3 Object Lock configuration permissions on your objects. This example sets the retention mode to COMPLIANCE and the retain until date to January 1, 2020. It creates a job that targets objects in the manifest bucket and reports the results in the reports bucket that you identified.

Using the AWS CLI

Example Set mention compliance across multiple objects

```
export AWS_PROFILE='aws-user'
export AWS_DEFAULT_REGION='us-west-2'
export ACCOUNT_ID=123456789012
export ROLE_ARN='arn:aws:iam::123456789012:role/bops-objectlock'

read -d '' OPERATION <<EOF
{
  "S3PutObjectRetention": {
    "Retention": {
      "RetainUntilDate": "2025-01-01T00:00:00",
      "Mode": "COMPLIANCE"
    }
  }
}
EOF

read -d '' MANIFEST <<EOF
{
  "Spec": {
    "Format": "S3BatchOperations_CSV_20180820",
    "Fields": [
      "Bucket",
      "Key"
    ],
  },
  "Location": {
```

```

"ObjectArn": "arn:aws:s3:::ManifestBucket/compliance-objects-manifest.csv",
"ETag": "Your-manifest-ETag"
}
}
EOF

read -d '' REPORT <<EOF
{
"Bucket": "arn:aws:s3:::ReportBucket",
"Format": "Report_CSV_20180820",
"Enabled": true,
"Prefix": "reports/compliance-objects-bops",
"ReportScope": "AllTasks"
}
EOF

aws \
s3control create-job \
--account-id "${ACCOUNT_ID}" \
--manifest "${MANIFEST//$/\n}" \
--operation "${OPERATION//$/\n/}" \
--report "${REPORT//$/\n}" \
--priority 10 \
--role-arn "${ROLE_ARN}" \
--client-request-token "$(uuidgen)" \
--region "${AWS_DEFAULT_REGION}" \
--description "Set compliance retain-until to 1 Jul 2030";

```

Example Extend the COMPLIANCE mode's retain until date to January 15, 2020

The following example extends the COMPLIANCE mode's retain until date to January 15, 2025.

```

export AWS_PROFILE='aws-user'
export AWS_DEFAULT_REGION='us-west-2'
export ACCOUNT_ID=123456789012
export ROLE_ARN='arn:aws:iam::123456789012:role/bops-objectlock'

read -d '' OPERATION <<EOF
{
"S3PutObjectRetention": {
"Retention": {
"RetainUntilDate": "2025-01-15T00:00:00",

```

```
"Mode": "COMPLIANCE"
}
}
}
EOF

read -d '' MANIFEST <<EOF
{
  "Spec": {
    "Format": "S3BatchOperations_CSV_20180820",
    "Fields": [
      "Bucket",
      "Key"
    ],
    "Location": {
      "ObjectArn": "arn:aws:s3:::ManifestBucket/compliance-objects-manifest.csv",
      "ETag": "Your-manifest-ETag"
    }
  }
}
EOF

read -d '' REPORT <<EOF
{
  "Bucket": "arn:aws:s3:::ReportBucket",
  "Format": "Report_CSV_20180820",
  "Enabled": true,
  "Prefix": "reports/compliance-objects-bops",
  "ReportScope": "AllTasks"
}
EOF

aws \
  s3control create-job \
  --account-id "${ACCOUNT_ID}" \
  --manifest "${MANIFEST//$'\n'}" \
  --operation "${OPERATION//$'\n'/{}" \
  --report "${REPORT//$'\n'}" \
  --priority 10 \
  --role-arn "${ROLE_ARN}" \
  --client-request-token "$(uuidgen)" \
  --region "${AWS_DEFAULT_REGION}" \
  --description "Extend compliance retention to 15 Jan 2020";
```

Using the AWS SDK for Java

Example Set the retention mode to COMPLIANCE and the retain until date to January 1, 2020.

```
public String createComplianceRetentionJob(final AWSS3ControlClient awss3ControlClient)
throws ParseException {
    final String manifestObjectArn = "arn:aws:s3:::ManifestBucket/compliance-objects-manifest.csv";
    final String manifestObjectVersionId = "your-object-version-Id";

    final JobManifestLocation manifestLocation = new JobManifestLocation()
        .withObjectArn(manifestObjectArn)
        .withETag(manifestObjectVersionId);

    final JobManifestSpec manifestSpec =
        new JobManifestSpec()
            .withFormat(JobManifestFormat.S3BatchOperations_CSV_20180820)
            .withFields("Bucket", "Key");

    final JobManifest manifestToPublicApi = new JobManifest()
        .withLocation(manifestLocation)
        .withSpec(manifestSpec);

    final String jobReportBucketArn = "arn:aws:s3:::ReportBucket";
    final String jobReportPrefix = "reports/compliance-objects-bops";

    final JobReport jobReport = new JobReport()
        .withEnabled(true)
        .withReportScope(JobReportScope.AllTasks)
        .withBucket(jobReportBucketArn)
        .withPrefix(jobReportPrefix)
        .withFormat(JobReportFormat.Report_CSV_20180820);

    final SimpleDateFormat format = new SimpleDateFormat("dd/MM/yyyy");
    final Date janFirst = format.parse("01/01/2020");

    final JobOperation jobOperation = new JobOperation()
        .withS3PutObjectRetention(new S3SetObjectRetentionOperation()
            .withRetention(new S3Retention()
                .withMode(S3ObjectLockRetentionMode.COMPLIANCE)
                .withRetainUntilDate(janFirst))));

    final String roleArn = "arn:aws:iam::123456789012:role/bops-object-lock";
    final Boolean requiresConfirmation = true;
```

```
final int priority = 10;

final CreateJobRequest request = new CreateJobRequest()
    .withAccountId("123456789012")
    .withDescription("Set compliance retain-until to 1 Jan 2020")
    .withManifest(manifestToPublicApi)
    .withOperation(jobOperation)
    .withPriority(priority)
    .withRoleArn(roleArn)
    .withReport(jobReport)
    .withConfirmationRequired(requiredConfirmation);

final CreateJobResult result = awss3ControlClient.createJob(request);

return result.get jobId();
}
```

Example Extending the COMPLIANCE mode's retain until date

The following example extends the COMPLIANCE mode's retain until date to January 15, 2020.

```
public String createExtendComplianceRetentionJob(final AWSS3ControlClient
awss3ControlClient) throws ParseException {
    final String manifestObjectArn = "arn:aws:s3:::ManifestBucket/compliance-objects-manifest.csv";
    final String manifestObjectVersionId = "15ad5ba069e6bbc465c77bf83d541385";

    final JobManifestLocation manifestLocation = new JobManifestLocation()
        .withObjectArn(manifestObjectArn)
        .withETag(manifestObjectVersionId);

    final JobManifestSpec manifestSpec =
        new JobManifestSpec()
            .withFormat(JobManifestFormat.S3BatchOperations_CSV_20180820)
            .withFields("Bucket", "Key");

    final JobManifest manifestToPublicApi = new JobManifest()
        .withLocation(manifestLocation)
        .withSpec(manifestSpec);

    final String jobReportBucketArn = "arn:aws:s3:::ReportBucket";
    final String jobReportPrefix = "reports/compliance-objects-bops";
```

```
final JobReport jobReport = new JobReport()
    .withEnabled(true)
    .withReportScope(JobReportScope.AllTasks)
    .withBucket(jobReportBucketArn)
    .withPrefix(jobReportPrefix)
    .withFormat(JobReportFormat.Report_CSV_20180820);

final SimpleDateFormat format = new SimpleDateFormat("dd/MM/yyyy");
final Date jan15th = format.parse("15/01/2020");

final JobOperation jobOperation = new JobOperation()
    .withS3PutObjectRetention(new S3SetObjectRetentionOperation()
        .withRetention(new S3Retention()
            .withMode(S3ObjectLockRetentionMode.COMPLIANCE)
            .withRetainUntilDate(jan15th)));

final String roleArn = "arn:aws:iam::123456789012:role/bops-object-lock";
final Boolean requiresConfirmation = true;
final int priority = 10;

final CreateJobRequest request = new CreateJobRequest()
    .withAccountId("123456789012")
    .withDescription("Extend compliance retention to 15 Jan 2020")
    .withManifest(manifestToPublicApi)
    .withOperation(jobOperation)
    .withPriority(priority)
    .withRoleArn(roleArn)
    .withReport(jobReport)
    .withConfirmationRequired(requiresConfirmation);

final CreateJobResult result = awss3ControlClient.createJob(request);

return result.get jobId();
}
```

Use S3 Batch Operations with S3 Object Lock retention governance mode

The following example builds on the previous example of creating a trust policy, and setting S3 Batch Operations and S3 Object Lock configuration permissions. It shows how to apply S3 Object Lock retention governance with the retain until date of January 30, 2025, across multiple objects. It creates a Batch Operations job that uses the manifest bucket and reports the results in the reports bucket.

Using the AWS CLI

Example Apply S3 Object Lock retention governance across multiple objects with the retain until date of January 30, 2020

```
export AWS_PROFILE='aws-user'
export AWS_DEFAULT_REGION='us-west-2'
export ACCOUNT_ID=123456789012
export ROLE_ARN='arn:aws:iam::123456789012:role/bops-objectlock'

read -d '' OPERATION <<EOF
{
  "S3PutObjectRetention": {
    "Retention": {
      "RetainUntilDate": "2025-01-30T00:00:00",
      "Mode": "GOVERNANCE"
    }
  }
}
EOF

read -d '' MANIFEST <<EOF
{
  "Spec": {
    "Format": "S3BatchOperations_CSV_20180820",
    "Fields": [
      "Bucket",
      "Key"
    ],
    "Location": {
      "ObjectArn": "arn:aws:s3:::ManifestBucket/governance-objects-manifest.csv",
      "ETag": "Your-manifest-ETag"
    }
  }
}
EOF

read -d '' REPORT <<EOF
{
  "Bucket": "arn:aws:s3:::ReportBucket",
  "Format": "Report_CSV_20180820",
  "Enabled": true,
  "Prefix": "reports/governance-objects",
  "ReportScope": "AllTasks"
```

```
}

EOF

aws \
    s3control create-job \
    --account-id "${ACCOUNT_ID}" \
    --manifest "${MANIFEST//$/\n}" \
    --operation "${OPERATION//$/\n/}" \

Example Bypass retention governance across multiple objects

The following example builds on the previous example of creating a trust policy, and setting S3 Batch Operations and S3 Object Lock configuration permissions. It shows how to bypass retention governance across multiple objects and creates a Batch Operations job that uses the manifest bucket and reports the results in the reports bucket.

```
export AWS_PROFILE='aws-user'

read -d '' bypass_governance_permissions <<EOF
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:BypassGovernanceRetention"
            ],
            "Resource": [
                "arn:aws:s3:::${ManifestBucket}/*"
            ]
        }
    ]
}
EOF

aws iam put-role-policy --role-name bops-objectlock --policy-name bypass-governance-
permissions --policy-document "${bypass_governance_permissions}"
```

```
export AWS_PROFILE='aws-user'
export AWS_DEFAULT_REGION='us-west-2'
export ACCOUNT_ID=123456789012
export ROLE_ARN='arn:aws:iam::123456789012:role/bops-objectlock'

read -d '' OPERATION <<EOF
{
  "S3PutObjectRetention": {
    "BypassGovernanceRetention": true,
    "Retention": {

--client-request-token "$(uuidgen)" \
--region "${AWS_DEFAULT_REGION}" \
--description "Remove governance retention";
```

Using the AWS SDK for Java

The following example builds on the previous example of creating a trust policy, and setting S3 Batch Operations and S3 Object Lock configuration permissions. It shows how to apply S3 Object Lock retention governance with the `retain until` date set to January 30, 2020 across multiple objects. It creates a Batch Operations job that uses the manifest bucket and reports the results in the reports bucket.

Example Apply S3 Object Lock retention governance across multiple objects with the retain until date of January 30, 2020

```
public String createGovernanceRetentionJob(final AWSS3ControlClient awss3ControlClient)
throws ParseException {
    final String manifestObjectArn = "arn:aws:s3:::ManifestBucket/governance-objects-manifest.csv";
    final String manifestObjectVersionId = "15ad5ba069e6bbc465c77bf83d541385";

    final JobManifestLocation manifestLocation = new JobManifestLocation()
        .withObjectArn(manifestObjectArn)
        .withETag(manifestObjectVersionId);

    final JobManifestSpec manifestSpec =
        new JobManifestSpec()
            .withFormat(JobManifestFormat.S3BatchOperations_CSV_20180820)
            .withFields("Bucket", "Key");

    final JobManifest manifestToPublicApi = new JobManifest()
        .withLocation(manifestLocation)
        .withSpec(manifestSpec);

    final String jobReportBucketArn = "arn:aws:s3:::ReportBucket";
    final String jobReportPrefix = "reports/governance-objects";
```

```
final JobReport jobReport = new JobReport()
    .withEnabled(true)
    .withReportScope(JobReportScope.AllTasks)
    .withBucket(jobReportBucketArn)
    .withPrefix(jobReportPrefix)
    .withFormat(JobReportFormat.Report_CSV_20180820);

final SimpleDateFormat format = new SimpleDateFormat("dd/MM/yyyy");
final Date jan30th = format.parse("30/01/2020");

final JobOperation jobOperation = new JobOperation()
    .withS3PutObjectRetention(new S3SetObjectRetentionOperation())
        .withRetention(new S3Retention()
            .withMode(S3ObjectLockRetentionMode.GOVERNANCE)
            .withRetainUntilDate(jan30th)));

final String roleArn = "arn:aws:iam::123456789012:role/bops-object-lock";
final Boolean requiresConfirmation = true;
final int priority = 10;

final CreateJobRequest request = new CreateJobRequest()
    .withAccountId("123456789012")
    .withDescription("Put governance retention")
    .withManifest(manifestToPublicApi)
    .withOperation(jobOperation)
    .withPriority(priority)
    .withRoleArn(roleArn)
    .withReport(jobReport)
    .withConfirmationRequired(requiresConfirmation);

final CreateJobResult result = awss3ControlClient.createJob(request);

return result.get jobId();
}
```

Example Bypass retention governance across multiple objects

The following example builds on the previous example of creating a trust policy, and setting S3 Batch Operations and S3 Object Lock configuration permissions. It shows how to bypass retention governance across multiple objects and creates a Batch Operations job that uses the manifest bucket and reports the results in the reports bucket.

```
public void allowBypassGovernance() {
```

```
final String roleName = "bops-object-lock";

final String bypassGovernancePermissions = "{" +
    "    \"Version\": \"2012-10-17\", " +
    "    \"Statement\": [" +
    "        {" +
    "            \"Effect\": \"Allow\", " +
    "            \"Action\": [" +
    "                \"s3:BypassGovernanceRetention\" " +
    "            ], " +
    "            \"Resource\": [" +
    "                \"arn:aws:s3:::ManifestBucket/*\" " +
    "            ]" +
    "        }" +
    "    ]" +
"}";

final AmazonIdentityManagement iam =
    AmazonIdentityManagementClientBuilder.defaultClient();

final PutRolePolicyRequest putRolePolicyRequest = new PutRolePolicyRequest()
    .withPolicyDocument(bypassGovernancePermissions)
    .withPolicyName("bypass-governance-permissions")
    .withRoleName(roleName);

    final PutRolePolicyResult putRolePolicyResult =
iam.putRolePolicy(putRolePolicyRequest);
}

public String createRemoveGovernanceRetentionJob(final AWSS3ControlClient
awss3ControlClient) {
    final String manifestObjectArn = "arn:aws:s3:::ManifestBucket/governance-objects-manifest.csv";
    final String manifestObjectVersionId = "15ad5ba069e6bbc465c77bf83d541385";

final JobReport jobReport = new JobReport()
    .withEnabled(true)
    .withReportScope(JobReportScope.AllTasks)
    .withBucket(jobReportBucketArn)
    .withPrefix(jobReportPrefix)
    .withFormat(JobReportFormat.Report_CSV_20180820);

final JobOperation jobOperation = new JobOperation()
    .withS3PutObjectRetention(new S3SetObjectRetentionOperation()
        .withRetention(new S3Retention()));

final String roleArn = "arn:aws:iam::123456789012:role/bops-object-lock";
final Boolean requiresConfirmation = true;
final int priority = 10;

final CreateJobRequest request = new CreateJobRequest()
    .withAccountId("123456789012")
    .withDescription("Remove governance retention")
    .withManifest(manifestToPublicApi)
    .withOperation(jobOperation)
    .withPriority(priority)
    .withRoleArn(roleArn)
    .withReport(jobReport)
    .withConfirmationRequired(requiresConfirmation);

final CreateJobResult result = awss3ControlClient.createJob(request);

return result.get jobId();
}
```

Using S3 Batch Operations to turn off S3 Object Lock legal hold

The following example builds on the previous examples of creating a trust policy, and setting S3 Batch Operations and S3 Object Lock configuration permissions. It shows how to disable Object Lock legal hold on objects using Batch Operations.

The example first updates the role to grant s3:PutObjectLegalHold permissions, creates a Batch Operations job that turns off (removes) legal hold from the objects identified in the manifest, and then reports on it.

Using the AWS CLI

Example Updates the role to grant s3:PutObjectLegalHold permissions

```
export AWS_PROFILE='aws-user'

read -d '' legal_hold_permissions <<EOF
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObjectLegalHold"
            ],
            "Resource": [
                "arn:aws:s3:::ManifestBucket/*"
            ]
        }
    ]
}

EOF

aws iam put-role-policy --role-name bops-objectlock --policy-name legal-hold-  
permissions --policy-document "${legal_hold_permissions}"
```

Example Turn off legal hold

The following example turns off legal hold.

```
export AWS_PROFILE='aws-user'
export AWS_DEFAULT_REGION='us-west-2'
export ACCOUNT_ID=123456789012
export ROLE_ARN='arn:aws:iam::123456789012:role/bops-objectlock'

read -d '' OPERATION <<EOF
{
    "S3PutObjectLegalHold": {
        "LegalHold": {
            "Value": false
        }
    }
}
```

```
        "Status": "OFF"
    }
}
}
EOF

read -d '' MANIFEST <<EOF
{
  "Spec": {
    "Format": "S3BatchOperations_CSV_20180820",
    "Fields": [
      "Bucket",
      "Key"
    ],
    "Location": {
      "ObjectArn": "arn:aws:s3:::ManifestBucket/legalhold-object-manifest.csv",
      "ETag": "Your-manifest-ETag"
    }
  }
}
EOF

read -d '' REPORT <<EOF
{
  "Bucket": "arn:aws:s3:::ReportBucket",
  "Format": "Report_CSV_20180820",
  "Enabled": true,
  "Prefix": "reports/legalhold-objects-bops",
  "ReportScope": "AllTasks"
}
EOF

aws \
  s3control create-job \
  --account-id "${ACCOUNT_ID}" \
  --manifest "${MANIFEST//$'\n'}" \
  --operation "${OPERATION//$'\n'/{}" \
  --report "${REPORT//$'\n'}" \
  --priority 10 \
  --role-arn "${ROLE_ARN}" \
  --client-request-token "$(uuidgen)" \
  --region "${AWS_DEFAULT_REGION}" \
  --description "Turn off legal hold";
```

Using the AWS SDK for Java

Example Updates the role to grant s3:PutObjectLegalHold permissions

```
public void allowPutObjectLegalHold() {
    final String roleName = "bops-object-lock";

    final String legalHoldPermissions = "{" +
        "    \"Version\": \"2012-10-17\", " +
        "    \"Statement\": [ " +
        "        { " +
        "            \"Effect\": \"Allow\", " +
        "            \"Action\": [ " +
        "                \"s3:PutObjectLegalHold\" " +
        "            ], " +
        "            \"Resource\": [ " +
        "                \"arn:aws:s3:::ManifestBucket/*\" " +
        "            ] " +
        "        } " +
        "    ] " +
    "}";

    final AmazonIdentityManagement iam =
        AmazonIdentityManagementClientBuilder.defaultClient();

    final PutRolePolicyRequest putRolePolicyRequest = new PutRolePolicyRequest()
        .withPolicyDocument(legalHoldPermissions)
        .withPolicyName("legal-hold-permissions")
        .withRoleName(roleName);

    final PutRolePolicyResult putRolePolicyResult =
    iam.putRolePolicy(putRolePolicyRequest);
}
```

Example Turn off legal hold

Use the example below if you want to turn off legal hold.

```
public String createLegalHoldOffJob(final AWSS3ControlClient awss3ControlClient) {
    final String manifestObjectArn = "arn:aws:s3:::ManifestBucket/legalhold-object-
manifest.csv";
    final String manifestObjectVersionId = "15ad5ba069e6bbc465c77bf83d541385";
```

```
final JobManifestLocation manifestLocation = new JobManifestLocation()
    .withObjectArn(manifestObjectArn)
    .withETag(manifestObjectVersionId);

final JobManifestSpec manifestSpec =
    new JobManifestSpec()
        .withFormat(JobManifestFormat.S3BatchOperations_CSV_20180820)
        .withFields("Bucket", "Key");

final JobManifest manifestToPublicApi = new JobManifest()
    .withLocation(manifestLocation)
    .withSpec(manifestSpec);

final String jobReportBucketArn = "arn:aws:s3:::ReportBucket";
final String jobReportPrefix = "reports/legalhold-objects-bops";

final JobReport jobReport = new JobReport()
    .withEnabled(true)
    .withReportScope(JobReportScope.AllTasks)
    .withBucket(jobReportBucketArn)
    .withPrefix(jobReportPrefix)
    .withFormat(JobReportFormat.Report_CSV_20180820);

final JobOperation jobOperation = new JobOperation()
    .withS3PutObjectLegalHold(new S3SetObjectLegalHoldOperation()
        .withLegalHold(new S3ObjectLockLegalHold()
            .withStatus(S3ObjectLockLegalHoldStatus.OFF))));

final String roleArn = "arn:aws:iam::123456789012:role/bops-object-lock";
final Boolean requiresConfirmation = true;
final int priority = 10;

final CreateJobRequest request = new CreateJobRequest()
    .withAccountId("123456789012")
    .withDescription("Turn off legal hold")
    .withManifest(manifestToPublicApi)
    .withOperation(jobOperation)
    .withPriority(priority)
    .withRoleArn(roleArn)
    .withReport(jobReport)
    .withConfirmationRequired(requiresConfirmation);

final CreateJobResult result = awss3ControlClient.createJob(request);
```

```
    return result.getJobId();
}
```

S3 Batch Operations tutorial

The following tutorial presents complete end-to-end procedures for some Batch Operations tasks.

- [Tutorial: Batch-transcoding videos with S3 Batch Operations, AWS Lambda, and AWS Elemental MediaConvert](#)

Monitoring Amazon S3

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. We recommend collecting monitoring data from all of the parts of your AWS solution so that you can more easily debug a multipoint failure if one occurs. Before you start monitoring Amazon S3, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

For more information about logging and monitoring in Amazon S3, see the following topics.

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [What is S3 Express One Zone?](#) and [Directory buckets](#).

Topics

- [Monitoring tools](#)
- [Logging options for Amazon S3](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)
- [Logging requests with server access logging](#)
- [Monitoring metrics with Amazon CloudWatch](#)
- [Amazon S3 Event Notifications](#)

Monitoring tools

AWS provides various tools that you can use to monitor Amazon S3. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon S3 and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring metrics with Amazon CloudWatch](#).
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

Manual monitoring tools

Another important part of monitoring Amazon S3 involves manually monitoring those items that the CloudWatch alarms don't cover. The Amazon S3, CloudWatch, Trusted Advisor, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. You might want to enable *server access logging*, which tracks requests for access to your bucket. Each access log record provides details about a single access request, such as the requester, bucket name, request time, request action, response status, and error code, if any. For more information, see [Logging requests with server access logging](#).

- The Amazon S3 dashboard shows the following:
 - Your buckets and the objects and properties they contain
- The CloudWatch home page shows the following:
 - Current alarms and status

- Graphs of alarms and resources
- Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services you care about.
- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.
- Create and edit alarms to be notified of problems.
- AWS Trusted Advisor can help you monitor your AWS resources to improve performance, reliability, security, and cost effectiveness. Four Trusted Advisor checks are available to all users; more than 50 checks are available to users with a Business or Enterprise support plan. For more information, see [AWS Trusted Advisor](#).

Trusted Advisor has these checks that relate to Amazon S3:

- Checks of the logging configuration of Amazon S3 buckets.
- Security checks for Amazon S3 buckets that have open access permissions.
- Fault tolerance checks for Amazon S3 buckets that do not have versioning enabled, or have versioning suspended.

Logging options for Amazon S3

You can record the actions that are taken by users, roles, or AWS services on Amazon S3 resources and maintain log records for auditing and compliance purposes. To do this, you can use server-access logging, AWS CloudTrail logging, or a combination of both. We recommend that you use CloudTrail for logging bucket-level and object-level actions for your Amazon S3 resources. For more information about each option, see the following sections:

- [Logging requests with server access logging](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)

The following table lists the key properties of CloudTrail logs and Amazon S3 server-access logs. To make sure that CloudTrail meets your security requirements, review the table and notes.

Log properties	AWS CloudTrail	Amazon S3 server logs
Can be forwarded to other systems (Amazon CloudWatch Logs, Amazon CloudWatch Events)	Yes	No
Deliver logs to more than one destination (for example, send the same logs to two different buckets)	Yes	No
Turn on logs for a subset of objects (prefix)	Yes	No
Cross-account log delivery (target and source bucket owned by different accounts)	Yes	No
Integrity validation of log file by using digital signature or hashing	Yes	No
Default or choice of encryption for log files	Yes	No
Object operations (by using Amazon S3 APIs)	Yes	Yes
Bucket operations (by using Amazon S3 APIs)	Yes	Yes
Searchable UI for logs	Yes	No
Fields for Object Lock parameters, Amazon S3 Select properties for log records	Yes	No

Log properties	AWS CloudTrail	Amazon S3 server logs
Fields for Object Size, Total Time, Turn-Around Time, and HTTP Referer for log records		Yes
Lifecycle transitions, expirations, restores		Yes
Logging of keys in a batch delete operation		Yes
Authentication failures ¹		Yes
Accounts where logs get delivered	Bucket owner ² , and requester	Bucket owner only
Performance and Cost	AWS CloudTrail	Amazon S3 Server Logs
Price	Management events (first delivery) are free; data events incur a fee, in addition to storage of logs	No other cost in addition to storage of logs
Speed of log delivery	Data events every 5 minutes; management events every 15 minutes	Within a few hours
Log format	JSON	Log file with space-separated, newline-delimited records

Notes

- CloudTrail does not deliver logs for requests that fail authentication (in which the provided credentials are not valid). However, it does include logs for requests in which authorization fails (AccessDenied) and requests that are made by anonymous users.
- The S3 bucket owner receives CloudTrail logs when the account does not have full access to the object in the request. For more information, see [Object-level actions in cross-account scenarios](#).

3. S3 does not support delivery of CloudTrail logs or server access logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them.

Logging Amazon S3 API calls using AWS CloudTrail

Amazon S3 is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon S3. CloudTrail captures a subset of API calls for Amazon S3 as events, including calls from the Amazon S3 console and code calls to Amazon S3 API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon S3. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, including how to configure and enable it, see the [AWS CloudTrail User Guide](#).

Using CloudTrail logs with Amazon S3 server access logs and CloudWatch Logs

AWS CloudTrail logs provide a record of actions taken by a user, role, or an AWS service in Amazon S3, while Amazon S3 server access logs provide detailed records for the requests that are made to an S3 bucket. For more information about how the different logs work, and their properties, performance, and costs, see [the section called "Logging options"](#).

You can use AWS CloudTrail logs together with server access logs for Amazon S3. CloudTrail logs provide you with detailed API tracking for Amazon S3 bucket-level and object-level operations. Server access logs for Amazon S3 provide you with visibility into object-level operations on your data in Amazon S3. For more information about server access logs, see [Logging requests with server access logging](#).

You can also use CloudTrail logs together with Amazon CloudWatch for Amazon S3. CloudTrail integration with CloudWatch Logs delivers S3 bucket-level API activity captured by CloudTrail to a CloudWatch log stream in the CloudWatch log group that you specify. You can create CloudWatch alarms for monitoring specific API activity and receive email notifications when the specific API activity occurs. For more information about CloudWatch alarms for monitoring specific API activity,

see the [AWS CloudTrail User Guide](#). For more information about using CloudWatch with Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

 **Note**

S3 does not support delivery of CloudTrail logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them.

CloudTrail tracking with Amazon S3 SOAP API calls

CloudTrail tracks Amazon S3 SOAP API calls. Amazon S3 SOAP support over HTTP is deprecated, but it is still available over HTTPS. For more information about Amazon S3 SOAP support, see [Appendix a: Using the SOAP API](#).

 **Important**

Newer Amazon S3 features are not supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.

Amazon S3 SOAP actions tracked by CloudTrail logging

SOAP API name	API event name used in CloudTrail log
ListAllMyBuckets	ListBuckets
CreateBucket	CreateBucket
DeleteBucket	DeleteBucket
GetBucketAccessControlPolicy	GetBucketAcl
SetBucketAccessControlPolicy	PutBucketAcl
GetBucketLoggingStatus	GetBucketLogging
SetBucketLoggingStatus	PutBucketLogging

For more information about CloudTrail and Amazon S3, see the following topics:

Topics

- [Amazon S3 CloudTrail events](#)
- [CloudTrail log file entries for Amazon S3 and S3 on Outposts](#)
- [Enabling CloudTrail event logging for S3 buckets and objects](#)
- [Identifying Amazon S3 requests using CloudTrail](#)

Amazon S3 CloudTrail events

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in Amazon S3, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for Amazon S3, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Creating a trail for your AWS account](#)
- [AWS services integrations with CloudTrail logs](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)
- [Receiving CloudTrail log files from multiple Regions](#)

- [Receiving CloudTrail log files from multiple accounts](#)

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or IAM user credentials
- Whether the request was made with temporary security credentials for a role or federated user
- Whether the request was made by another AWS service

For more information, see the [CloudTrail userIdentity Element](#).

You can store your log files in your bucket for as long as you want, but you can also define Amazon S3 Lifecycle rules to archive or delete log files automatically. By default, your log files are encrypted by using Amazon S3 server-side encryption (SSE).

How CloudTrail captures requests made to Amazon S3

By default, CloudTrail logs S3 bucket-level API calls that were made in the last 90 days, but not log requests made to objects. Bucket-level calls include events such as `CreateBucket`, `DeleteBucket`, `PutBucketLifecycle`, `PutBucketPolicy`, and so on. You can see bucket-level events on the CloudTrail console. However, you can't view data events (Amazon S3 object-level calls) there—you must parse or query CloudTrail logs for them.

Amazon S3 account-level actions tracked by CloudTrail logging

CloudTrail logs account-level actions. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

The tables in this section list the Amazon S3 account-level actions that are supported for logging by CloudTrail.

Amazon S3 account-level API actions tracked by CloudTrail logging appear as the following event names. The CloudTrail event names differ from the API action name. For example, `DeletePublicAccessBlock` is `DeleteAccountPublicAccessBlock`.

- [DeleteAccountPublicAccessBlock](#)
- [GetAccountPublicAccessBlock](#)

- [PutAccountPublicAccessBlock](#)

Amazon S3 bucket-level actions that are tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for general purpose buckets. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

This section lists the Amazon S3 bucket-level actions that are supported for logging by CloudTrail.

Amazon S3 bucket-level API actions tracked by CloudTrail logging appear as the following event names. In some cases, the CloudTrail event name differs from the API action name. For example, PutBucketLifecycleConfiguration is PutBucketLifecycle.

- [CreateBucket](#)
- [DeleteBucket](#)
- [DeleteBucketAnalyticsConfiguration](#)
- [DeleteBucketCors](#)
- [DeleteBucketEncryption](#)
- [DeleteBucketIntelligentTieringConfiguration](#)
- [DeleteBucketInventoryConfiguration](#)
- [DeleteBucketLifecycle](#)
- [DeleteBucketMetricsConfiguration](#)
- [DeleteBucketOwnershipControls](#)
- [DeleteBucketPolicy](#)
- [DeleteBucketPublicAccessBlock](#)
- [DeleteBucketReplication](#)
- [DeleteBucketTagging](#)
- [GetAccelerateConfiguration](#)
- [GetBucketAcl](#)
- [GetBucketAnalyticsConfiguration](#)
- [GetBucketCors](#)
- [GetBucketEncryption](#)

- [GetBucketIntelligentTieringConfiguration](#)
- [GetBucketInventoryConfiguration](#)
- [GetBucketLifecycle](#)
- [GetBucketLocation](#)
- [GetBucketLogging](#)
- [GetBucketMetricsConfiguration](#)
- [GetBucketNotification](#)
- [GetBucketObjectLockConfiguration](#)
- [GetBucketOwnershipControls](#)
- [GetBucketPolicy](#)
- [GetBucketPolicyStatus](#)
- [GetBucketPublicAccessBlock](#)
- [GetBucketReplication](#)
- [GetBucketRequestPayment](#)
- [GetBucketTagging](#)
- [GetBucketVersioning](#)
- [GetBucketWebsite](#)
- [HeadBucket](#)
- [ListBuckets](#)
- [PutAccelerateConfiguration](#)
- [PutBucketAcl](#)
- [PutBucketAnalyticsConfiguration](#)
- [PutBucketCors](#)
- [PutBucketEncryption](#)
- [PutBucketIntelligentTieringConfiguration](#)
- [PutBucketInventoryConfiguration](#)
- [PutBucketLifecycle](#)
- [PutBucketLogging](#)
- [PutBucketMetricsConfiguration](#)
- [PutBucketNotification](#)

- [PutBucketObjectLockConfiguration](#)
- [PutBucketOwnershipControls](#)
- [PutBucketPolicy](#)
- [PutBucketPublicAccessBlock](#)
- [PutBucketReplication](#)
- [PutBucketRequestPayment](#)
- [PutBucketTagging](#)
- [PutBucketVersioning](#)
- [PutBucketWebsite](#)

In addition to these API operations, you can also use the [OPTIONS object](#) object-level action. This action is treated like a bucket-level action in CloudTrail logging because the action checks the CORS configuration of a bucket.

S3 Express One Zone bucket-level (Regional API endpoint) actions tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for directory buckets as management events. The eventsource for CloudTrail management events for S3 Express One Zone is `s3express.amazonaws.com`.

 **Note**

For S3 Express One Zone, CloudTrail logging of Zonal endpoint (object-level, or data plane) API operations (for example, `PutObject` or `GetObject`) is not supported.

These following Regional endpoint API operations are logged to CloudTrail.

- [CreateBucket](#)
- [DeleteBucket](#)
- [DeleteBucketPolicy](#)
- [GetBucketPolicy](#)
- [PutBucketPolicy](#)

- [ListDirectoryBuckets](#)

For more information, see [Security best practices for S3 Express One Zone](#).

Amazon S3 object-level actions that are tracked by AWS CloudTrail logging

You can also get CloudTrail logs for object-level Amazon S3 actions. To do this, enable data events for your S3 bucket or all buckets in your account. When an object-level action occurs in your account, CloudTrail evaluates your trail settings. If the event matches the object that you specified in a trail, the event is logged. For more information, see [Enabling CloudTrail event logging for S3 buckets and objects](#) and [Logging Data Events for Trails](#) in the *AWS CloudTrail User Guide*.

 **Note**

S3 doesn't support the delivery of CloudTrail logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them.

Amazon S3 object-level API actions tracked by CloudTrail logging appear as the following event names. In some cases, the CloudTrail event name differs from the API action name.

- [AbortMultipartUpload](#)
- [CompleteMultipartUpload](#)
- [CopyObject](#)
- [CreateMultipartUpload](#)
- [DeleteObject](#)
- [DeleteObjectTagging](#)
- [DeleteObjects](#)
- [GetObject](#)
- [GetObjectAcl](#)
- [GetObjectAttributes](#)
- [GetObjectLockLegalHold](#)
- [GetObjectLockRetention](#)
- [GetObjectTagging](#)
- [GetObjectTorrent](#)

- [HeadObject](#)
- [ListMultipartUploads](#)
- [ListObjectVersions](#)
- [ListObjects](#)
- [ListParts](#)
- [PutObject](#)
- [PutObjectAcl](#)
- [PutObjectLockLegalHold](#)
- [PutObjectLockRetention](#)
- [PutObjectTagging](#)
- [RestoreObject](#)
- [SelectObjectContent](#)
- [UploadPart](#)
- [UploadPartCopy](#)

Object-level actions in cross-account scenarios

The following are special use cases involving the object-level API calls in cross-account scenarios and how CloudTrail logs are reported. CloudTrail delivers logs to the requester (the account that made the API call), except in some access denied cases where log entries are redacted or omitted. When setting up cross-account access, consider the examples in this section.

 **Note**

The examples assume that CloudTrail logs are appropriately configured.

Example 1: CloudTrail delivers logs to the bucket owner

CloudTrail delivers logs to the bucket owner even if the bucket owner does not have permissions for the same object API operation. Consider the following cross-account scenario:

- Account A owns the bucket.
- Account B (the requester) tries to access an object in that bucket.
- Account C owns the object. Account C might or might not be the same account as Account A.

Note

CloudTrail always delivers object-level API logs to the requester (Account B). In addition, CloudTrail also delivers the same logs to the bucket owner (Account A) even when the bucket owner does not own the object (Account C) or have permissions for those same API operations on that object.

Example 2: CloudTrail does not proliferate email addresses that are used in setting object ACLs

Consider the following cross-account scenario:

- Account A owns the bucket.
- Account B (the requester) sends a request to set an object ACL grant by using an email address.
For more information about ACLs, see [Access control list \(ACL\) overview](#).

The requester gets the logs along with the email information. However, the bucket owner—if they are eligible to receive logs, as in example 1—gets the CloudTrail log reporting the event. However, the bucket owner doesn't get the ACL configuration information, specifically the grantee email address and the grant. The only information that the log tells the bucket owner is that an ACL API call was made by Account B.

CloudTrail log file entries for Amazon S3 and S3 on Outposts

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single

request from any source. It includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

For more information, see the following examples.

Topics

Example: Amazon S3 on Outposts log file entries

Amazon S3 on Outposts management events are available via AWS CloudTrail. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#). In addition, you can optionally [enable logging for data events in AWS CloudTrail](#).

A *trail* is a configuration that enables delivery of events as log files to an S3 bucket in a Region that you specify. CloudTrail logs for your Outposts buckets include a new field, `edgeDeviceDetails`, which identifies the Outpost where the specified bucket is located.

Additional log fields include the requested action, the date and time of the action, and the request parameters. CloudTrail log files are not an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates a [PutObject](#) action on s3-outposts.

```
{  
    "eventVersion": "1.08",  
    "userIdentity": {  
        "type": "IAMUser",  
        "principalId": "111122223333",  
        "arn": "arn:aws:iam::111122223333:user/yourUserName",  
        "accountId": "222222222222",  
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",  
        "userName": "yourUserName"  
},  
    "eventTime": "2020-11-30T15:44:33Z",  
    "eventSource": "s3-outposts.amazonaws.com",  
    "eventName": "PutObject",  
    "awsRegion": "us-east-1",  

```

```
    "ETag": "d41d8cd98f00b204e9800998ecf8427f"

Enabling CloudTrail event logging for S3 buckets and objects

You can use CloudTrail data events to get information about bucket and object-level requests in Amazon S3. To enable CloudTrail data events for all of your buckets or for a list of specific buckets, you must [create a trail manually in CloudTrail](#).

Note

- The default setting for CloudTrail is to find only management events. Check to ensure that you have the data events enabled for your account.
- With an S3 bucket that is generating a high workload, you could quickly generate thousands of logs in a short amount of time. Be mindful of how long you choose to enable CloudTrail data events for a busy bucket.

CloudTrail stores Amazon S3 data event logs in an S3 bucket of your choosing. Consider using a bucket in a separate AWS account to better organize events from multiple buckets that you might own into a central place for easier querying and analysis. AWS Organizations helps you create an AWS account that is linked to the account that owns the bucket that you're monitoring. For more information, see [What is AWS Organizations?](#) in the *AWS Organizations User Guide*.

When you create a trail in CloudTrail, in the data events section, you can select the **Select all S3 buckets in your account** check box to log all object-level events.

Note

- It's a best practice to create a lifecycle configuration for your AWS CloudTrail data event bucket. Configure the lifecycle configuration to periodically remove log files after the period of time you believe you need to audit them. Doing so reduces the amount of data that Athena analyzes for each query. For more information, see [Setting lifecycle configuration on a bucket](#).
- For more information about logging format, see [Logging Amazon S3 API calls using AWS CloudTrail](#).
- For examples of how to query CloudTrail logs, see the *AWS Big Data Blog* post [Analyze Security, Compliance, and Operational Activity Using AWS CloudTrail and Amazon Athena](#).

Enable logging for objects in a bucket using the console

You can use the Amazon S3 console to configure an AWS CloudTrail trail to log data events for objects in an S3 bucket. CloudTrail supports logging Amazon S3 object-level API operations such as `GetObject`, `DeleteObject`, and `PutObject`. These events are called *data events*.

By default, CloudTrail trails don't log data events, but you can configure trails to log data events for S3 buckets that you specify, or to log data events for all the Amazon S3 buckets in your AWS account. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

CloudTrail does not populate data events in the CloudTrail event history. Additionally, not all bucket-level actions are populated in the CloudTrail event history. For more information about the Amazon S3 bucket-level API actions tracked by CloudTrail logging, see [Amazon S3 bucket-level actions that are tracked by CloudTrail logging](#). For more information about how to query CloudTrail logs, see the AWS Knowledge Center article about [using Amazon CloudWatch Logs filter patterns and Amazon Athena to query CloudTrail logs](#).

To configure a trail to log data events for an S3 bucket, you can use either the AWS CloudTrail console or the Amazon S3 console. If you are configuring a trail to log data events for all the Amazon S3 buckets in your AWS account, it's easier to use the CloudTrail console. For information about using the CloudTrail console to configure a trail to log S3 data events, see [Data events](#) in the [AWS CloudTrail User Guide](#).

 **Important**

Additional charges apply for data events. For more information, see [AWS CloudTrail pricing](#).

The following procedure shows how to use the Amazon S3 console to configure a CloudTrail trail to log data events for an S3 bucket.

To enable CloudTrail data events logging for objects in an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket.
3. Choose **Properties**.
4. Under **AWS CloudTrail data events**, choose **Configure in CloudTrail**.

You can create a new CloudTrail trail or reuse an existing trail and configure Amazon S3 data events to be logged in your trail. For information about how to create trails in the CloudTrail console, see [Creating and updating a trail with the console](#) in the *AWS CloudTrail User Guide*. For information about how to configure Amazon S3 data event logging in the CloudTrail console, see [Logging data events for Amazon S3 Objects](#) in the *AWS CloudTrail User Guide*.

 **Note**

If you use the CloudTrail console or the Amazon S3 console to configure a trail to log data events for an S3 bucket, the Amazon S3 console shows that object-level logging is enabled for the bucket.

To disable CloudTrail data events logging for objects in an S3 bucket

1. Sign in to the AWS Management Console and open the CloudTrail console at <https://console.aws.amazon.com/cloudtrail/>.
2. In the left navigation pane, choose **Trails**.
3. Choose the name of the trail that you created to log events for your bucket.
4. On the details page for your trail, choose **Stop logging** in the upper-right corner.
5. In the dialog box that appears, choose **Stop logging**.

For information about enabling object-level logging when you create an S3 bucket, see [Creating a bucket](#).

For more information about CloudTrail logging with S3 buckets, see the following topics:

- [Viewing the properties for an S3 bucket](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)
- [Working with CloudTrail Log Files](#) in the *AWS CloudTrail User Guide*

Identifying Amazon S3 requests using CloudTrail

In Amazon S3, you can identify requests using an AWS CloudTrail event log. AWS CloudTrail is the preferred way of identifying Amazon S3 requests, but if you are using Amazon S3 server access logs, see [the section called “Identifying S3 requests”](#).

Topics

- [Identifying requests made to Amazon S3 in a CloudTrail log](#)
- [Identifying Amazon S3 Signature Version 2 requests by using CloudTrail](#)
- [Identifying access to S3 objects by using CloudTrail](#)

Identifying requests made to Amazon S3 in a CloudTrail log

After you set up CloudTrail to deliver events to a bucket, you should start to see objects go to your destination bucket on the Amazon S3 console. These are formatted as follows:

s3://*DOC-EXAMPLE-BUCKET1*/AWSLogs/*111122223333*/CloudTrail/*Region*/*yyyy/mm/dd*

Events logged by CloudTrail are stored as compressed, gzipped JSON objects in your S3 bucket. To efficiently find requests, you should use a service like Amazon Athena to index and query the CloudTrail logs.

For more information about CloudTrail and Athena, see [Creating the table for AWS CloudTrail logs in Athena using partition projection](#) in the *Amazon Athena User Guide*.

Identifying Amazon S3 Signature Version 2 requests by using CloudTrail

You can use a CloudTrail event log to identify which API signature version was used to sign a request in Amazon S3. This capability is important because support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use *Signature Version 4* signing.

We *strongly* recommend that you use CloudTrail to help determine whether any of your workflows are using Signature Version 2 signing. Remediate them by upgrading your libraries and code to use Signature Version 4 instead to prevent any impact to your business.

For more information, see [Announcement: AWS CloudTrail for Amazon S3 adds new fields for enhanced security auditing](#) in AWS re:Post.

Note

CloudTrail events for Amazon S3 include the signature version in the request details under the key name of 'additionalEventData'. To find the signature version on requests made for objects in Amazon S3 such as GET, PUT, and DELETE requests, you must enable CloudTrail data events. (This feature is turned off by default.)

AWS CloudTrail is the preferred method for identifying Signature Version 2 requests. If you're using Amazon S3 server-access logs, see [Identifying Signature Version 2 requests by using Amazon S3 access logs](#).

Topics

- [Athena query examples for identifying Amazon S3 Signature Version 2 requests](#)
- [Partitioning Signature Version 2 data](#)

Athena query examples for identifying Amazon S3 Signature Version 2 requests

Example — Select all Signature Version 2 events, and print only EventTime, S3_Action, Request_Parameters, Region, SourceIP, and UserAgent

In the following Athena query, replace `s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table` with your Athena details, and increase or remove the limit as needed.

```
SELECT EventTime, EventName as S3_Action, requestParameters as Request_Parameters,  
awsregion as AWS_Region, sourceipaddress as Source_IP, useragent as User_Agent  
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE eventsource='s3.amazonaws.com'  
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'  
LIMIT 10;
```

Example — Select all requesters that are sending Signature Version 2 traffic

```
SELECT useridentity.arn, Count(requestid) as RequestCount  
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE eventsource='s3.amazonaws.com'  
and json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'  
Group by useridentity.arn
```

Partitioning Signature Version 2 data

If you have a large amount of data to query, you can reduce the costs and running time of Athena by creating a partitioned table.

To do this, create a new table with partitions as follows.

```
CREATE EXTERNAL TABLE s3_cloudtrail_events_db.cloudtrail_table_partitioned(
    eventversion STRING,
    userIdentity STRUCT<
        type:STRING,
        principalid:STRING,
        arn:STRING,
        accountid:STRING,
        invokedby:STRING,
        accesskeyid:STRING,
        userName:STRING,
        sessioncontext:STRUCT<
            attributes:STRUCT<
                mfaauthenticated:STRING,
                creationdate:STRING>,
            sessionIssuer:STRUCT<
                type:STRING,
                principalId:STRING,
                arn:STRING,
                accountId:STRING,
                userName:STRING>
        >
    >,
    eventTime STRING,
    eventSource STRING,
    eventName STRING,
    awsRegion STRING,
    sourceIpAddress STRING,
    userAgent STRING,
    errorCode STRING,
    errorMessage STRING,
    requestParameters STRING,
    responseElements STRING,
    additionalEventData STRING,
    requestId STRING,
    eventId STRING,
    resources ARRAY<STRUCT<ARN:STRING,accountId: STRING,type:STRING>>,
    eventType STRING,
    apiVersion STRING,
    readOnly STRING,
    recipientAccountId STRING,
    serviceEventDetails STRING,
```

```
    sharedEventID STRING,  
    vpcEndpointId STRING  
)  
PARTITIONED BY (region string, year string, month string, day string)  
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'  
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'  
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'  
LOCATION 's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/';
```

Then, create the partitions individually. You can't get results from dates that you haven't created.

```
ALTER TABLE s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table_partitioned ADD  
PARTITION (region= 'us-east-1', year= '2019', month= '02', day= '19') LOCATION  
's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/CloudTrail/us-east-1/2019/02/19/'  
PARTITION (region= 'us-west-1', year= '2019', month= '02', day= '19') LOCATION  
's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/CloudTrail/us-west-1/2019/02/19/'  
PARTITION (region= 'us-west-2', year= '2019', month= '02', day= '19') LOCATION  
's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/CloudTrail/us-west-2/2019/02/19/'  
PARTITION (region= 'ap-southeast-1', year= '2019', month= '02', day= '19') LOCATION  
's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/CloudTrail/ap-southeast-1/2019/02/19/'  
PARTITION (region= 'ap-southeast-2', year= '2019', month= '02', day= '19') LOCATION  
's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/CloudTrail/ap-southeast-2/2019/02/19/'  
PARTITION (region= 'ap-northeast-1', year= '2019', month= '02', day= '19') LOCATION  
's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/CloudTrail/ap-northeast-1/2019/02/19/'  
PARTITION (region= 'eu-west-1', year= '2019', month= '02', day= '19') LOCATION  
's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/CloudTrail/eu-west-1/2019/02/19/'  
PARTITION (region= 'sa-east-1', year= '2019', month= '02', day= '19') LOCATION  
's3://DOC-EXAMPLE-BUCKET1/AWSLogs/111122223333/CloudTrail/sa-east-1/2019/02/19/';
```

You can then make the request based on these partitions, and you don't need to load the full bucket.

```
SELECT useridentity.arn,  
Count(requestid) AS RequestCount  
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table_partitioned  
WHERE eventsource='s3.amazonaws.com'  
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'  
AND region='us-east-1'  
AND year='2019'
```

```
AND month='02'  
AND day='19'  
Group by useridentity.arn
```

Identifying access to S3 objects by using CloudTrail

You can use your AWS CloudTrail event logs to identify Amazon S3 object access requests for data events such as `GetObject`, `DeleteObject`, and `PutObject`, and discover additional information about those requests.

The following example shows how to get all PUT object requests for Amazon S3 from an AWS CloudTrail event log.

Topics

- [Athena query examples for identifying Amazon S3 object access requests](#)

Athena query examples for identifying Amazon S3 object access requests

In the following Athena query examples, replace

s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table with your Athena details, and modify the date range as needed.

Example — Select all events that have PUT object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT  
    eventTime,  
    eventName,  
    eventSource,  
    sourceIpAddress,  
    userAgent,  
    json_extract_scalar(requestParameters, '$.bucketName') as bucketName,  
    json_extract_scalar(requestParameters, '$.key') as object,  
    userIdentity.arn as userArn  
FROM  
    s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE  
    eventName = 'PutObject'  
    AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Select all events that have GET object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT
    eventTime,
    eventName,
    eventSource,
    sourceIpAddress,
    userAgent,
    json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
    json_extract_scalar(requestParameters, '$.key') as object,
    userIdentity.arn as userArn
FROM
    s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table
WHERE
    eventName = 'GetObject'
    AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Select all anonymous requester events to a bucket in a certain period and print only EventTime, EventName, EventSource, SourceIP, UserAgent, BucketName, UserARN, and AccountID

```
SELECT
    eventTime,
    eventName,
    eventSource,
    sourceIpAddress,
    userAgent,
    json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
    userIdentity.arn as userArn,
    userIdentity.accountId
FROM
    s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table
WHERE
    userIdentity.accountId = 'anonymous'
    AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Identify all requests that required an ACL for authorization

The following Amazon Athena query example shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. If the request required an ACL for authorization, the aclRequired value in additionalEventData is Yes. If no ACLs

were required, `aclRequired` is not present. You can use this information to migrate those ACL permissions to the appropriate bucket policies. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see [Prerequisites for disabling ACLs](#).

```
SELECT
    eventTime,
    eventName,
    eventSource,
    sourceIpAddress,
    userAgent,
    userIdentity.arn as userArn,
    json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
    json_extract_scalar(requestParameters, '$.key') as object,
    json_extract_scalar(additionalEventData, '$.aclRequired') as aclRequired
FROM
    s3_cLOUDTRAIL_EVENTS_DB.cLOUDTRAIL_TABLE
WHERE
    json_extract_scalar(additionalEventData, '$.aclRequired') = 'Yes'
    AND eventTime BETWEEN '2022-05-10T00:00:00Z' and '2022-08-10T00:00:00Z'
```

 **Note**

- These query examples can also be useful for security monitoring. You can review the results for `PutObject` or `GetObject` calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.

If you are using Amazon S3 server access logs, see [Identifying object access requests by using Amazon S3 access logs](#).

Logging requests with server access logging

Server access logging provides detailed records for the requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

Note

Server access logs don't record information about wrong-Region redirect errors for Regions that launched after March 20, 2019. Wrong-Region redirect errors occur when a request for an object or bucket is made outside the Region in which the bucket exists.

How do I enable log delivery?

To enable log delivery, perform the following basic steps. For details, see [Enabling Amazon S3 server access logging](#).

- 1. Provide the name of the destination bucket** (also known as a *target bucket*). This bucket is where you want Amazon S3 to save the access logs as objects. Both the source and destination buckets must be in the same AWS Region and owned by the same account. The destination bucket must not have an S3 Object Lock default retention period configuration. The destination bucket must also not have Requester Pays enabled.

You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. But for simpler log management, we recommend that you save access logs in a different bucket.

When your source bucket and destination bucket are the same bucket, additional logs are created for the logs that are written to the bucket, which creates an infinite loop of logs. We do not recommend doing this because it could result in a small increase in your storage billing. In addition, the extra logs about logs might make it harder to find the log that you are looking for.

If you choose to save access logs in the source bucket, we recommend that you specify a destination prefix (also known as a *target prefix*) for all log object keys. When you specify a prefix, all the log object names begin with a common string, which makes the log objects easier to identify.

- 2. (Optional) Assign a destination prefix to all Amazon S3 log object keys.** The destination prefix (also known as a *target prefix*) makes it simpler for you to locate the log objects. For example, if you specify the prefix value `logs/`, each log object that Amazon S3 creates begins with the `logs/` prefix in its key, for example:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

If you specify the prefix value logs, the log object appears as follows:

```
logs2013-11-01-21-32-16-E568B2907131C0C0
```

[Prefixes](#) are also useful to distinguish between source buckets when multiple buckets log to the same destination bucket.

This prefix can also help when you delete the logs. For example, you can set a lifecycle configuration rule for Amazon S3 to delete objects with a specific prefix. For more information, see [Deleting Amazon S3 log files](#).

3. (Optional) Set permissions so that others can access the generated logs. By default, only the bucket owner always has full access to the log objects. If your destination bucket uses the Bucket owner enforced setting for S3 Object Ownership to disable access control lists (ACLs), you can't grant permissions in destination grants (also known as *target grants*) that use ACLs. However, you can update your bucket policy for the destination bucket to grant access to others. For more information, see [Identity and access management in Amazon S3](#) and [Permissions for log delivery](#).

4. (Optional) Set a log object key format for the log files. You have two options for the log object key format (also known as the *target object key format*):

- **Non-date-based partitioning** – This is the original log object key format. If you choose this format, the log file key format appears as follows:

```
[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For example, if you specify logs/ as the prefix, your log objects are named like this:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

- **Date-based partitioning** – If you choose date-based partitioning, you can choose the event time or delivery time for the log file as the date source used in the log format. This format makes it easier to query the logs.

If you choose date-based partitioning, the log file key format appears as follows:

```
[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For example, if you specify logs/ as the target prefix, your log objects are named like this:

```
logs/123456789012/us-west-2/DOC-EXAMPLE-SOURCE-
BUCKET/2023/03/01/2023-03-01-21-32-16-E568B2907131C0C0
```

For delivery time delivery, the time in the log file names corresponds to the delivery time for the log files.

For event time delivery, the year, month, and day correspond to the day on which the event occurred, and the hour, minutes and seconds are set to 00 in the key. The logs delivered in these log files are for a specific day only.

If you're configuring your logs through the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API, use TargetObjectKeyFormat to specify the log object key format.

To specify non-date-based partitioning, use SimplePrefix. To specify data-based partitioning, use PartitionedPrefix. If you use PartitionedPrefix, use PartitionDataSource to specify either EventTime or DeliveryTime.

For SimplePrefix, the log file key format appears as follows:

```
[TargetPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For PartitionedPrefix with event time or delivery time, the log file key format appears as follows:

```
[TargetPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/
[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

Log object key format

Amazon S3 uses the following object key formats for the log objects that it uploads in the destination bucket:

- **Non-date-based partitioning** – This is the original log object key format. If you choose this format, the log file key format appears as follows:

[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]

- **Date-based partitioning** – If you choose date-based partitioning, you can choose the event time or delivery time for the log file as the date source used in the log format. This format makes it easier to query the logs.

If you choose date-based partitioning, the log file key format appears as follows:

[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/
[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]

In the log object key, YYYY, MM, DD, hh, mm, and ss are the digits of the year, month, day, hour, minute, and seconds (respectively). These dates and times are in Coordinated Universal Time (UTC).

A log file delivered at a specific time can contain records written at any point before that time. There is no way to know whether all log records for a certain time interval have been delivered or not.

The UniqueString component of the key is there to prevent overwriting of files. It has no meaning, and log processing software should ignore it.

How are logs delivered?

Amazon S3 periodically collects access log records, consolidates the records in log files, and then uploads log files to your destination bucket as log objects. If you enable logging on multiple source buckets that identify the same destination bucket, the destination bucket will have access logs for all those source buckets. However, each log object reports access log records for a specific source bucket.

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. We recommend that you update the bucket policy on the destination bucket to grant access to the logging service principal (`logging.s3.amazonaws.com`) for access log delivery. You can also grant access for access log delivery to the S3 log delivery group through your bucket access control list (ACL). However, granting access to the S3 log delivery group by using your bucket ACL is not recommended.

When you enable server access logging and grant access for access log delivery through your destination bucket policy, you must update the policy to allow `s3:PutObject` access for the

logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the destination bucket policy to grant these permissions to the logging service principal. For more information about granting permissions for server access log delivery, see [Permissions for log delivery](#).

 **Note**

Server access logs aren't delivered to the requester or the bucket owner for virtual private cloud (VPC) endpoint requests if the VPC endpoint policy denies such requests.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. You must update the bucket policy on the destination bucket to grant access to the logging service principal. For more information about Object Ownership, see [Grant access to the S3 log delivery group for server access logging](#).

Best-effort server log delivery

Server access log records are delivered on a best-effort basis. Most requests for a bucket that is properly configured for logging result in a delivered log record. Most log records are delivered within a few hours of the time that they are recorded, but they can be delivered more frequently.

The completeness and timeliness of server logging is not guaranteed. The log record for a particular request might be delivered long after the request was actually processed, or *it might not be delivered at all*. It is possible that you might even see a duplication of a log record. The purpose of server logs is to give you an idea of the nature of traffic against your bucket. Although log records are rarely lost or duplicated, be aware that server logging is not meant to be a complete accounting of all requests.

Because of the best-effort nature of server logging, your usage reports might include one or more access requests that do not appear in a delivered server log. You can find these usage reports under **Cost & usage reports** in the AWS Billing and Cost Management console.

Bucket logging status changes take effect over time

Changes to the logging status of a bucket take time to actually affect the delivery of log files. For example, if you enable logging for a bucket, some requests made in the following hour might be

logged, and others might not. Suppose that you change the destination bucket for logging from bucket A to bucket B. For the next hour, some logs might continue to be delivered to bucket A, whereas others might be delivered to the new destination bucket B. In all cases, the new settings eventually take effect without any further action on your part.

For more information about logging and log files, see the following sections:

Topics

- [Enabling Amazon S3 server access logging](#)
- [Amazon S3 server access log format](#)
- [Deleting Amazon S3 log files](#)
- [Using Amazon S3 server access logs to identify requests](#)

Enabling Amazon S3 server access logging

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

By default, Amazon S3 doesn't collect server access logs. When you enable logging, Amazon S3 delivers access logs for a source bucket to a destination bucket (also known as a *target bucket*) that you choose. The destination bucket must be in the same AWS Region and AWS account as the source bucket.

An access log record contains details about the requests that are made to a bucket. This information can include the request type, the resources that are specified in the request, and the time and date that the request was processed. For more information about logging basics, see [Logging requests with server access logging](#).

Important

- There is no extra charge for enabling server access logging on an Amazon S3 bucket. However, any log files that the system delivers to you will accrue the usual charges for storage. (You can delete the log files at any time.) We do not assess data-transfer charges for log file delivery, but we do charge the normal data-transfer rate for accessing the log files.

- Your destination bucket should not have server access logging enabled. You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. However, delivering logs to the source bucket will cause an infinite loop of logs and is not recommended. For simpler log management, we recommend that you save access logs in a different bucket. For more information, see [How do I enable log delivery?](#)
- S3 buckets that have S3 Object Lock enabled can't be used as destination buckets for server access logs. Your destination bucket must not have a default retention period configuration.
- The destination bucket must not have Requester Pays enabled.
- You can use [default bucket encryption](#) on the destination bucket *only* if you use server-side encryption with Amazon S3 managed keys (SSE-S3), which uses the 256-bit Advanced Encryption Standard (AES-256). Default server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) is not supported.

You can enable or disable server access logging by using the Amazon S3 console, Amazon S3 API, the AWS Command Line Interface (AWS CLI), or AWS SDKs.

Permissions for log delivery

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. For access log delivery, you must grant the logging service principal (`logging.s3.amazonaws.com`) access to your destination bucket.

To grant permissions to Amazon S3 for log delivery, you can use either a bucket policy or bucket access control lists (ACLs), depending on your destination bucket's S3 Object Ownership settings. However, we recommend that you use a bucket policy instead of ACLs.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. In this case, you must update the bucket policy for the destination bucket to grant access to the logging service principal. You can't update your bucket ACL to grant access to the S3 log delivery group. You also can't include destination grants (also known as *target grants*) in your [PutBucketLogging](#) configuration.

For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see [Grant access to the S3 log delivery group for server access logging](#). For more information about Object Ownership, see [Controlling ownership of objects and disabling ACLs for your bucket](#). When you create new buckets, ACLs are disabled by default.

Granting access by using a bucket policy

To grant access by using the bucket policy on the destination bucket, update the bucket policy to grant the s3:PutObject permission to the logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the bucket policy on the destination bucket to grant this permission to the logging service principal. If you enable server access logging programmatically, you must manually update the bucket policy for the destination bucket to grant access to the logging service principal.

For an example bucket policy that grants access to the logging service principal, see [the section called “Grant permissions to the logging service principal by using a bucket policy”](#).

Granting access by using bucket ACLs

You can alternately use bucket ACLs to grant access for access log delivery. You add a grant entry to the bucket ACL that grants WRITE and READ_ACP permissions to the S3 log delivery group.

However, granting access to the S3 log delivery group by using bucket ACLs is not recommended.

For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see [Grant access to the S3 log delivery group for server access logging](#). For an example ACL that grants access to the logging service principal, see [the section called “Grant permissions to the log delivery group by using a bucket ACL”](#).

Grant permissions to the logging service principal by using a bucket policy

This example bucket policy grants the s3:PutObject permission to the logging service principal (logging.s3.amazonaws.com). To use this bucket policy, replace the *user input placeholders* with your own information. In the following policy, **DOC-EXAMPLE-DESTINATION-BUCKET** is the destination bucket where server access logs will be delivered, and **DOC-EXAMPLE-SOURCE-BUCKET** is the source bucket. **EXAMPLE-LOGGING-PREFIX** is the optional destination prefix (also known as a *target prefix*) that you want to use for your log objects. **SOURCE-ACCOUNT-ID** is the AWS account that owns the source bucket.

Note

If there are Deny statements in your bucket policy, make sure that they don't prevent Amazon S3 from delivering access logs.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "S3ServerAccessLogsPolicy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "logging.s3.amazonaws.com"  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/EXAMPLE-LOGGING-PREFIX*",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "SOURCE-ACCOUNT-ID"  
                }  
            }  
        }  
    ]  
}
```

Grant permissions to the log delivery group by using a bucket ACL

Note

As a security best practice, Amazon S3 disables access control lists (ACLs) by default in all new buckets. For more information about ACL permissions in the Amazon S3 console, see [Configuring ACLs](#).

Although we do not recommend this approach, you can grant permissions to the log delivery group by using a bucket ACL. However, if the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination grants (also known as *target grants*) in your [PutBucketLogging](#) configuration. Instead, you must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see [Permissions for log delivery](#).

In the bucket ACL, the log delivery group is represented by the following URL:

```
http://acs.amazonaws.com/groups/s3/LogDelivery
```

To grant WRITE and READ_ACP (ACL read) permissions, add the following grants to the destination bucket ACL:

```
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
  </Grantee>
  <Permission>WRITE</Permission>
</Grant>
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
  </Grantee>
  <Permission>READ_ACP</Permission>
</Grant>
```

For examples of adding ACL grants programmatically, see [Configuring ACLs](#).

Important

When you enable Amazon S3 server access logging by using AWS CloudFormation on a bucket and you're using ACLs to grant access to the S3 log delivery group, you must also add "AccessControl": "LogDeliveryWrite" to your CloudFormation template. Doing so is important because you can grant those permissions only by creating an ACL for the bucket, but you can't create custom ACLs for buckets in CloudFormation. You can use only canned ACLs with CloudFormation.

To enable server access logging

To enable server access logging by using the Amazon S3 console, Amazon S3 REST API, AWS SDKs, and AWS CLI, use the following procedures.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to enable server access logging for.
3. Choose **Properties**.
4. In the **Server access logging** section, choose **Edit**.
5. Under **Server access logging**, choose **Enable**.
6. Under **Destination bucket**, specify a bucket and an optional prefix. If you specify a prefix, we recommend including a forward slash (/) after the prefix to make it easier to find your logs.

Note

Specifying a prefix with a slash (/) makes it simpler for you to locate the log objects. For example, if you specify the prefix value logs/, each log object that Amazon S3 creates begins with the logs/ prefix in its key, as follows:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

If you specify the prefix value logs, the log object appears as follows:

```
logs2013-11-01-21-32-16-E568B2907131C0C0
```

7. Under **Log object key format**, do one of the following:

- To choose non-date-based partitioning, choose **[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**.
- To choose date-based partitioning, choose **[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**, then choose **S3 event time** or **Log file delivery time**.

8. Choose **Save changes**.

When you enable server access logging on a bucket, the console both enables logging on the source bucket and updates the bucket policy for the destination bucket to grant the s3:PutObject permission to the logging service principal (logging.s3.amazonaws.com). For more information about this bucket policy, see [Grant permissions to the logging service principal by using a bucket policy](#).

You can view the logs in the destination bucket. After you enable server access logging, it might take a few hours before the logs are delivered to the target bucket. For more information about how and when logs are delivered, see [How are logs delivered?](#)

For more information, see [Viewing the properties for an S3 bucket](#).

Using the REST API

To enable logging, you submit a [PutBucketLogging](#) request to add the logging configuration on the source bucket. The request specifies the destination bucket (also known as a *target bucket*) and, optionally, the prefix to be used with all log object keys.

The following example identifies **DOC-EXAMPLE-DESTINATION-BUCKET** as the destination bucket and **logs/** as the prefix.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>DOC-EXAMPLE-DESTINATION-BUCKET</TargetBucket>
    <TargetPrefix>logs/</TargetPrefix>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The following example identifies **DOC-EXAMPLE-DESTINATION-BUCKET** as the destination bucket, **logs/** as the prefix, and EventTime as the log object key format.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>DOC-EXAMPLE-DESTINATION-BUCKET</TargetBucket>
    <TargetPrefix>logs/</TargetPrefix>
    <TargetObjectKeyFormat>
      <PartitionedPrefix>
        <PartitionDataSource>EventTime</PartitionDataSource>
      </PartitionedPrefix>
    </TargetObjectKeyFormat>
```

```
</LoggingEnabled>  
</BucketLoggingStatus>
```

The log objects are written and owned by the S3 log delivery account, and the bucket owner is granted full permissions on the log objects. You can optionally use destination grants (also known as *target grants*) to grant permissions to other users so that they can access the logs. For more information, see [PutBucketLogging](#).

 **Note**

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't use destination grants to grant permissions to other users. To grant permissions to others, you can update the bucket policy on the destination bucket. For more information, see [Permissions for log delivery](#).

To retrieve the logging configuration on a bucket, use the [GetBucketLogging](#) API operation.

To delete the logging configuration, you send a PutBucketLogging request with an empty BucketLoggingStatus:

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">  
</BucketLoggingStatus>
```

To enable logging on a bucket, you can use either the Amazon S3 API or the AWS SDK wrapper libraries.

Using the AWS SDKs

The following examples enable logging on a bucket. You must create two buckets, a source bucket and a destination (target) bucket. The examples update the bucket ACL on the destination bucket first. They then grant the log delivery group the necessary permissions to write logs to the destination bucket, and then they enable logging on the source bucket.

These examples won't work on destination buckets that use the Bucket owner enforced setting for Object Ownership.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your

[PutBucketLogging](#) configuration. You must use a bucket policy to grant access to the logging service principal (logging.s3.amazonaws.com). For more information, see [Permissions for log delivery](#).

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

        .build());
}

}
```

{

Using the AWS CLI

We recommend that you create a dedicated logging bucket in each AWS Region that you have S3 buckets in. Then have your Amazon S3 access logs delivered to that S3 bucket. For more information and examples, see [put-bucket-logging](#) in the *AWS CLI Reference*.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your [PutBucketLogging](#) configuration. You must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see [Permissions for log delivery](#).

Example — Enable access logs with five buckets across two Regions

In this example, you have the following five buckets:

- 1-DOC-EXAMPLE-BUCKET1-us-east-1

- 2-DOC-EXAMPLE-BUCKET1-us-east-1
- 3-DOC-EXAMPLE-BUCKET1-us-east-1
- 1-DOC-EXAMPLE-BUCKET1-us-west-2
- 2-DOC-EXAMPLE-BUCKET1-us-west-2

 **Note**

The final step of the following procedure provides example bash scripts that you can use to create your logging buckets and enable server access logging on these buckets. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in the following procedure.

1. Create two logging destination buckets in the US West (Oregon) and US East (N. Virginia) Regions and give them the following names:
 - DOC-EXAMPLE-BUCKET1-logs-us-east-1
 - DOC-EXAMPLE-BUCKET1-logs-us-west-2
2. Later in these steps, you will enable server access logging as follows:
 - 1-DOC-EXAMPLE-BUCKET1-us-east-1 logs to the S3 bucket DOC-EXAMPLE-BUCKET1-logs-us-east-1 with the prefix 1-DOC-EXAMPLE-BUCKET1-us-east-1
 - 2-DOC-EXAMPLE-BUCKET1-us-east-1 logs to the S3 bucket DOC-EXAMPLE-BUCKET1-logs-us-east-1 with the prefix 2-DOC-EXAMPLE-BUCKET1-us-east-1
 - 3-DOC-EXAMPLE-BUCKET1-us-east-1 logs to the S3 bucket DOC-EXAMPLE-BUCKET1-logs-us-east-1 with the prefix 3-DOC-EXAMPLE-BUCKET1-us-east-1
 - 1-DOC-EXAMPLE-BUCKET1-us-west-2 logs to the S3 bucket DOC-EXAMPLE-BUCKET1-logs-us-west-2 with the prefix 1-DOC-EXAMPLE-BUCKET1-us-west-2
 - 2-DOC-EXAMPLE-BUCKET1-us-west-2 logs to the S3 bucket DOC-EXAMPLE-BUCKET1-logs-us-west-2 with the prefix 2-DOC-EXAMPLE-BUCKET1-us-west-2
3. For each destination logging bucket, grant permissions for server access log delivery by using a bucket ACL or a bucket policy:

- **Update the bucket policy** (Recommended) – To grant permissions to the logging service principal, use the following put-bucket-policy command. Replace *DOC-EXAMPLE-DESTINATION-BUCKET-logs* with the name of your destination bucket.

```
aws s3api put-bucket-policy --bucket DOC-EXAMPLE-DESTINATION-BUCKET-logs --policy file://policy.json
```

Policy.json is a JSON document in the current folder that contains the following bucket policy. To use this bucket policy, replace the *user input placeholders* with your own information. In the following policy, *DOC-EXAMPLE-DESTINATION-BUCKET-logs* is the destination bucket where server access logs will be delivered, and *DOC-EXAMPLE-SOURCE-BUCKET* is the source bucket. *SOURCE-ACCOUNT-ID* is the AWS account that owns the source bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "S3ServerAccessLogsPolicy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "logging.s3.amazonaws.com"  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET-logs/*",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "SOURCE-ACCOUNT-ID"  
                }  
            }  
        }  
    ]  
}
```

- **Update the bucket ACL** – To grant permissions to the S3 log delivery group, use the following put-bucket-acl command. Replace *DOC-EXAMPLE-DESTINATION-BUCKET-logs* with the name of your destination (target) bucket.

```
aws s3api put-bucket-acl --bucket DOC-EXAMPLE-DESTINATION-BUCKET-logs --grant-write URI=http://acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp URI=http://acs.amazonaws.com/groups/s3/LogDelivery
```

4. Then, create a logging.json file that contains your logging configuration (based on one of the three examples that follow). After you create the logging.json file, you can apply the logging configuration by using the following put-bucket-logging command. Replace *DOC-EXAMPLE-DESTINATION-BUCKET-logs* with the name of your destination (target) bucket.

```
aws s3api put-bucket-logging --bucket DOC-EXAMPLE-DESTINATION-BUCKET-logs --bucket-logging-status file://logging.json
```

 **Note**

Instead of using this put-bucket-logging command to apply the logging configuration on each destination bucket, you can use one of the bash scripts provided in the next step. To use those scripts, you must create the policy.json and logging.json files, as described in this procedure.

The logging.json file is a JSON document in the current folder that contains your logging configuration. If a destination bucket uses the Bucket owner enforced setting for Object Ownership, your logging configuration can't contain destination (target) grants. For more information, see [Permissions for log delivery](#).

Example – logging.json without destination (target) grants

The following example logging.json file doesn't contain destination (target) grants. Therefore, you can apply this configuration to a destination (target) bucket that uses the Bucket owner enforced setting for Object Ownership.

```
{  
    "LoggingEnabled": {  
        "TargetBucket": "DOC-EXAMPLE-DESTINATION-BUCKET-logs",  
        "TargetPrefix": "DOC-EXAMPLE-DESTINATION-BUCKET/"  
    }  
}
```

Example – logging.json with destination (target) grants

The following example logging.json file contains destination (target) grants.

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't include destination (target) grants in your [PutBucketLogging](#) configuration. For more information, see [Permissions for log delivery](#).

```
{  
    "LoggingEnabled": {  
        "TargetBucket": "DOC-EXAMPLE-DESTINATION-BUCKET-logs",  
        "TargetPrefix": "DOC-EXAMPLE-DESTINATION-BUCKET/",  
        "TargetGrants": [  
            {  
                "Grantee": {  
                    "Type": "AmazonCustomerByEmail",  
                    "EmailAddress": "user@example.com"  
                },  
                "Permission": "FULL_CONTROL"  
            }  
        ]  
    }  
}
```

Example – logging.json with the log object key format set to S3 event time

The following logging.json file changes the log object key format to S3 event time. For more information about setting the log object key format, see [the section called “How do I enable log delivery?”](#)

```
{  
    "LoggingEnabled": {  
        "TargetBucket": "DOC-EXAMPLE-DESTINATION-BUCKET-logs",  
        "TargetPrefix": "DOC-EXAMPLE-DESTINATION-BUCKET/",  
        "TargetObjectKeyFormat": {  
            "PartitionedPrefix": {  
                "PartitionDataSource": "EventTime"  
            }  
        }  
    }  
}
```

5. Use one of the following bash scripts to add access logging for all the buckets in your account. Replace *DOC-EXAMPLE-DESTINATION-BUCKET-Logs* with the name of your destination (target) bucket, and replace *us-west-2* with the name of the Region that your buckets are located in.

 **Note**

This script works only if all of your buckets are in the same Region. If you have buckets in multiple Regions, you must adjust the script.

Example – Grant access with bucket policies and add logging for the buckets in your account

```
loggingBucket='DOC-EXAMPLE-DESTINATION-BUCKET-Logs'  
region='us-west-2'  
  
# Create the logging bucket.  
aws s3 mb s3://$loggingBucket --region $region  
  
aws s3api put-bucket-policy --bucket $loggingBucket --policy file://policy.json  
  
# List the buckets in this account.  
buckets="$(aws s3 ls | awk '{print $3}')"
```

```
# Put a bucket logging configuration on each bucket.
for bucket in $buckets
    do
        # This if statement excludes the logging bucket.
        if [ "$bucket" != "$loggingBucket" ] ; then
            continue;
        fi
        printf '{\n        "LoggingEnabled": {\n            "TargetBucket": "%s",\n            "TargetPrefix": "%s/"\n        }\n}' "$loggingBucket" "$bucket" > logging.json
        aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
        echo "$bucket done"
    done

    rm logging.json

echo "Complete"
```

Example – Grant access with bucket ACLs and add logging for the buckets in your account

```
loggingBucket='DOC-EXAMPLE-DESTINATION-BUCKET-logs'
region='us-west-2'

# Create the logging bucket.
aws s3 mb s3://$loggingBucket --region $region

aws s3api put-bucket-acl --bucket $loggingBucket --grant-write URI=http://
acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp URI=http://
acs.amazonaws.com/groups/s3/LogDelivery

# List the buckets in this account.
buckets="$(aws s3 ls | awk '{print $3}')"

# Put a bucket logging configuration on each bucket.
for bucket in $buckets
    do
```

```
# This if statement excludes the logging bucket.
if [ "$bucket" != "$loggingBucket" ] ; then
    continue;
fi
printf '{'
    "LoggingEnabled": {
        "TargetBucket": "%s",
        "TargetPrefix": "%s/"
    }
}' "$loggingBucket" "$bucket" > logging.json
aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
echo "$bucket done"
done

rm logging.json

echo "Complete"
```

Verifying your server access logs setup

After you enable server access logging, complete the following steps:

- Access the destination bucket and verify that the log files are being delivered. After the access logs are set up, it might take longer than an hour for all requests to be properly logged and delivered. You can also automatically verify log delivery by using Amazon S3 request metrics and setting up Amazon CloudWatch alarms for these metrics. For more information, see [Monitoring metrics with Amazon CloudWatch](#).
- Verify that you are able to open and read the contents of the log files.

For server access logging troubleshooting information, see [Troubleshoot server access logging](#).

Amazon S3 server access log format

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. You can use server access logs for the following purposes:

- Performing security and access audits
- Learning about your customer base

- Understanding your Amazon S3 bill

This section describes the format and other details about Amazon S3 server access log files.

Server access log files consist of a sequence of newline-delimited log records. Each log record represents one request and consists of space-delimited fields.

The following is an example log consisting of five log records.

```

Log record fields

The following list describes the log record fields.

Bucket Owner

The canonical user ID of the owner of the source bucket. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see [AWS account identifiers](#) in the *AWS General Reference*. For information about how to find the canonical user ID for your account, see [Finding the canonical user ID for your AWS account](#).

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that the request was processed against. If the system receives a malformed request and cannot determine the bucket, the request will not appear in any server access log.

Example entry

DOC-EXAMPLE-BUCKET1**Time**

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: [%d/%b/%Y:%H:%M:%S %z]

Example entry

[06/Feb/2019:00:00:38 +0000]

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

192.0.2.3

Requester

The canonical user ID of the requester, or a - for unauthenticated requests. If the requester was an IAM user, this field returns the requester's IAM user name along with the AWS account root user that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be

Request ID

A string generated by Amazon S3 to uniquely identify each request.

Example entry

3E57427F33A59F07

Operation

The operation listed here is declared as SOAP.*operation*, REST.*HTTP_method.resource_type*, WEBSITE.*HTTP_method.resource_type*, or BATCH.DELETE.OBJECT, or S3.action.resource_type for [Lifecycle and logging](#).

Example entry

```
REST.PUT.OBJECT
```

Key

The key (object name) part of the request.

Example entry

```
/photos/2019/08/puppy.jpg
```

Request-URI

The Request-URI part of the HTTP request message.

Example Entry

```
"GET /DOC-EXAMPLE-BUCKET1/photos/2019/08/puppy.jpg?x-foo=bar HTTP/1.1"
```

HTTP status

The numeric HTTP status code of the response.

Example entry

```
200
```

Error Code

The Amazon S3 [Error code](#), or - if no error occurred.

Example entry

NoSuchBucket

Bytes Sent

The number of response bytes sent, excluding HTTP protocol overhead, or - if zero.

Example entry

2662992

Object Size

The total size of the object in question.

Example entry

3462992

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

70

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

10

Referer

The value of the HTTP Referer header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP User-Agent header.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID in the request, or - if the operation doesn't take a `versionId` parameter.

Example entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The `x-amz-id-2` or Amazon S3 extended request ID.

Example entry

```
s9lzHYrFp76ZVxRcpX9+5cjAnEH2ROuNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsip/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request or a - for unauthenticated requests.

Example entry

SigV2

Cipher Suite

The Secure Sockets Layer (SSL) cipher that was negotiated for an HTTPS request or a - for HTTP.

Example entry

ECDHE-RSA-AES128-GCM-SHA256

Authentication Type

The type of request authentication used: AuthHeader for authentication headers, QueryString for query string (presigned URL), or a - for unauthenticated requests.

Example entry

AuthHeader

Host Header

The endpoint used to connect to Amazon S3.

Example entry

s3.us-west-2.amazonaws.com

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see [Legacy endpoints](#). For a complete list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: TLSv1.1, TLSv1.2, TLSv1.3, or - if TLS wasn't used.

Example entry

TLSv1.2

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a -. For more information about access points, see [Using access points](#). For more information about ARNs, see [Amazon Resource Name \(ARN\)](#) in the [AWS Reference Guide](#).

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is Yes. If no ACLs were required, the string is -. For more information about ACLs, see [Access control list \(ACL\) overview](#). For more information about using the aclRequired field to disable ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Example entry

```
Yes
```

Additional logging for copy operations

A copy operation involves a GET and a PUT. For that reason, we log two records when performing a copy operation. The previous section describes the fields related to the PUT part of the operation. The following list describes the fields in the record that relate to the GET part of the copy operation.

Bucket Owner

The canonical user ID of the bucket that stores the object being copied. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see [AWS account identifiers](#) in the [AWS General Reference](#). For information about how to find the canonical user ID for your account, see [Finding the canonical user ID for your AWS account](#).

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that stores the object that's being copied.

Example entry

```
DOC-EXAMPLE-BUCKET1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: [%d/%B/%Y:%H:%M:%S %z]

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a - for unauthenticated requests. If the requester was an IAM user, this field will return the requester's IAM user name along with the AWS account root user that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be

Request ID

A string generated by Amazon S3 to uniquely identify each request.

Example entry

3E57427F33A59F07

Operation

The operation listed here is declared as SOAP.*operation*, REST.*HTTP_method.resource_type*, WEBSITE.*HTTP_method.resource_type*, or BATCH.DELETE.OBJECT.

Example entry

REST.COPY.OBJECT_GET

Key

The key (object name) of the object being copied, or - if the operation doesn't take a key parameter.

Example entry

/photos/2019/08/puppy.jpg

Request-URI

The Request-URI part of the HTTP request message.

Example entry

"GET /DOC-EXAMPLE-BUCKET1/photos/2019/08/puppy.jpg?x-foo=bar"

HTTP status

The numeric HTTP status code of the GET portion of the copy operation.

Example entry

200

Error Code

The Amazon S3 [Error code](#) of the GET portion of the copy operation, or - if no error occurred.

Example entry

NoSuchBucket

Bytes Sent

The number of response bytes sent, excluding the HTTP protocol overhead, or - if zero.

Example entry

2662992

Object Size

The total size of the object in question.

Example entry

3462992

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

70

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

```
10
```

Referer

The value of the HTTP Referer header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP User-Agent header.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID of the object being copied, or - if the x-amz-copy-source header didn't specify a versionId parameter as part of the copy source.

Example Entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The x-amz-id-2 or Amazon S3 extended request ID.

Example entry

```
s9lzMHyxFp76ZVxRcpX9+5cjAnEH2R0uNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request, or a `-` for unauthenticated requests.

Example entry

```
SigV4
```

Cipher Suite

The Secure Sockets Layer (SSL) cipher that was negotiated for an HTTPS request, or a `-` for HTTP.

Example entry

```
ECDHE-RSA-AES128-GCM-SHA256
```

Authentication Type

The type of request authentication used: `AuthHeader` for authentication headers, `QueryString` for query strings (presigned URLs), or a `-` for unauthenticated requests.

Example entry

```
AuthHeader
```

Host Header

The endpoint that was used to connect to Amazon S3.

Example entry

```
s3.us-west-2.amazonaws.com
```

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see [Legacy endpoints](#). For a complete

list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: TLSv1.1, TLSv1.2, TLSv1.3, or - if TLS wasn't used.

Example entry

```
TLSv1.2
```

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a -. For more information about access points, see [Using access points](#). For more information about ARNs, see [Amazon Resource Name \(ARN\)](#) in the *AWS Reference Guide*.

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is Yes. If no ACLs were required, the string is -. For more information about ACLs, see [Access control list \(ACL\) overview](#). For more information about using the aclRequired field to disable ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Example entry

```
Yes
```

Custom access log information

You can include custom information to be stored in the access log record for a request. To do this, add a custom query-string parameter to the URL for the request. Amazon S3 ignores query-string

parameters that begin with x-, but includes those parameters in the access log record for the request, as part of the Request-URI field of the log record.

For example, a GET request for "s3.amazonaws.com/DOC-EXAMPLE-BUCKET1/photos/2019/08/puppy.jpg?x-user=johndoe" works the same as the request for "s3.amazonaws.com/DOC-EXAMPLE-BUCKET1/photos/2019/08/puppy.jpg", except that the "x-user=johndoe" string is included in the Request-URI field for the associated log record. This functionality is available in the REST interface only.

Programming considerations for extensible server access log format

Occasionally, we might extend the access log record format by adding new fields to the end of each line. Therefore, make sure that any of your code that parses server access logs can handle trailing fields that it might not understand.

Deleting Amazon S3 log files

An Amazon S3 bucket with server access logging enabled can accumulate many server log objects over time. Your application might need these access logs for a specific period after they are created, and after that, you might want to delete them. You can use Amazon S3 Lifecycle configuration to set rules so that Amazon S3 automatically queues these objects for deletion at the end of their life.

You can define a lifecycle configuration for a subset of objects in your S3 bucket by using a shared prefix. If you specified a prefix in your server access logging configuration, you can set a lifecycle configuration rule to delete log objects that have that prefix.

For example, suppose that your log objects have the prefix logs/. You can set a lifecycle configuration rule to delete all objects in the bucket that have the prefix logs/ after a specified period of time.

For more information about lifecycle configuration, see [Managing your storage lifecycle](#).

For general information about server access logging, see [Logging requests with server access logging](#).

Using Amazon S3 server access logs to identify requests

You can identify Amazon S3 requests by using Amazon S3 server access logs.

Note

- To identify Amazon S3 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to set up and contain more information. For more information, see [Identifying Amazon S3 requests using CloudTrail](#).
- Depending on how many access requests you get, analyzing your logs might require more resources or time than using CloudTrail data events.

Topics

- [Querying access logs for requests by using Amazon Athena](#)
- [Identifying Signature Version 2 requests by using Amazon S3 access logs](#)
- [Identifying object access requests by using Amazon S3 access logs](#)

Querying access logs for requests by using Amazon Athena

You can identify Amazon S3 requests with Amazon S3 access logs by using Amazon Athena.

Amazon S3 stores server access logs as objects in an S3 bucket. It is often easier to use a tool that can analyze the logs in Amazon S3. Athena supports analysis of S3 objects and can be used to query Amazon S3 access logs.

Example

The following example shows how you can query Amazon S3 server access logs in Amazon Athena. Replace the *user input placeholders* used in the following examples with your own information.

Note

To specify an Amazon S3 location in an Athena query, you must provide an S3 URI for the bucket where your logs are delivered to. This URI must include the bucket name and prefix in the following format: s3://*DOC-EXAMPLE-BUCKET1*-logs/*prefix*/

1. Open the Athena console at <https://console.aws.amazon.com/athena/>.

2. In the Query Editor, run a command similar to the following. Replace `s3_access_logs_db` with the name that you want to give to your database.

```
CREATE DATABASE s3_access_logs_db
```

 **Note**

It's a best practice to create the database in the same AWS Region as your S3 bucket.

3. In the Query Editor, run a command similar to the following to create a table schema in the database that you created in step 2. Replace `s3_access_logs_db.mybucket_logs` with the name that you want to give to your table. The STRING and BIGINT data type values are the access log properties. You can query these properties in Athena. For LOCATION, enter the S3 bucket and prefix path as noted earlier.

```
CREATE EXTERNAL TABLE `s3_access_logs_db.mybucket_logs`(  
`bucketowner` STRING,  
`bucket_name` STRING,  
`requestdatetime` STRING,  
`remoteip` STRING,  
`requester` STRING,  
`requestid` STRING,  
`operation` STRING,  
`key` STRING,  
`request_uri` STRING,  
`httpstatus` STRING,  
`errorcode` STRING,  
`bytesent` BIGINT,  
`objectsize` BIGINT,  
`totaltime` STRING,  
`turnaroundtime` STRING,  
`referrer` STRING,  
`useragent` STRING,  
`versionid` STRING,  
`hostid` STRING,  
`sigv` STRING,  
`ciphersuite` STRING,  
`authtype` STRING,  
`endpoint` STRING,  
`tlsversion` STRING,  
`accesspointarn` STRING,
```

4. In the navigation pane, under **Database**, choose your database.
 5. Under **Tables**, choose **Preview table** next to your table name.

In the **Results** pane, you should see data from the server access logs, such as `bucketowner`, `bucket`, `requestdatetime`, and so on. This means that you successfully created the Athena table. You can now query the Amazon S3 server access logs.

Example — Show who deleted an object and when (timestamp, IP address, and IAM user)

```
SELECT requestdatetime, remoteip, requester, key  
FROM s3_access_logs_db.mybucket_logs  
WHERE key = 'images/picture.jpg' AND operation like '%DELETE%';
```

Example — Show all operations that were performed by an IAM user

```
SELECT *  
FROM s3_access_logs_db.mybucket_logs  
WHERE requester='arn:aws:iam::123456789123:user/user_name';
```

Example — Show all operations that were performed on an object in a specific time period

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE Key='prefix/images/picture.jpg'
    AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
    BETWEEN parse_datetime('2017-02-18:07:00:00','yyyy-MM-dd:HH:mm:ss')
    AND parse_datetime('2017-02-18:08:00:00','yyyy-MM-dd:HH:mm:ss');
```

Example — Show how much data was transferred to a specific IP address in a specific time period

```
SELECT coalesce(SUM(bytessent), 0) AS bytessenttotal
FROM s3_access_logs_db.mybucket_logs
WHERE remoteip='192.0.2.1'
    AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
    BETWEEN parse_datetime('2022-06-01','yyyy-MM-dd')
    AND parse_datetime('2022-07-01','yyyy-MM-dd');
```

Note

To reduce the time that you retain your logs, you can create an S3 Lifecycle configuration for your server access logs bucket. Create lifecycle configuration rules to remove log files periodically. Doing so reduces the amount of data that Athena analyzes for each query. For more information, see [Setting lifecycle configuration on a bucket](#).

Identifying Signature Version 2 requests by using Amazon S3 access logs

Amazon S3 support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use Signature Version 4 signing. You can identify Signature Version 2 access requests by using Amazon S3 access logs.

Note

To identify Signature Version 2 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to

set up and contain more information than server access logs. For more information, see [Identifying Amazon S3 Signature Version 2 requests by using CloudTrail](#).

Example — Show all requesters that are sending Signature Version 2 traffic

```
SELECT requester, sigv, Count(sigv) as sigcount
FROM s3_access_logs_db.mybucket_logs
GROUP BY requester, sigv;
```

Identifying object access requests by using Amazon S3 access logs

You can use queries on Amazon S3 server access logs to identify Amazon S3 object access requests, for operations such as GET, PUT, and DELETE, and discover further information about those requests.

The following Amazon Athena query example shows how to get all PUT object requests for Amazon S3 from a server access log.

Example — Show all requesters that are sending PUT object requests in a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db
WHERE operation='REST.PUT.OBJECT' AND
parse_datetime(requestdatetime, 'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
AND
parse_datetime('2019-07-02:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query example shows how to get all GET object requests for Amazon S3 from the server access log.

Example — Show all requesters that are sending GET object requests in a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db
WHERE operation='REST.GET.OBJECT' AND
```

```
parse_datetime(requestdatetime, 'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
AND
parse_datetime('2019-07-02:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query example shows how to get all anonymous requests to your S3 buckets from the server access log.

Example — Show all anonymous requesters that are making requests to a bucket during a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE requester IS NULL AND
parse_datetime(requestdatetime, 'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
AND
parse_datetime('2019-07-02:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. You can use this information to migrate those ACL permissions to the appropriate bucket policies and disable ACLs. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see [Prerequisites for disabling ACLs](#).

Example — Identify all requests that required an ACL for authorization

```
SELECT bucket_name, requester, key, operation, aclrequired, requestdatetime
FROM s3_access_logs_db
WHERE aclrequired = 'Yes' AND
parse_datetime(requestdatetime, 'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2022-05-10:00:00:00', 'yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2022-08-10:00:00:00', 'yyyy-MM-dd:HH:mm:ss')
```

Note

- You can modify the date range as needed to suit your needs.

- These query examples might also be useful for security monitoring. You can review the results for PutObject or GetObject calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.
- If you are using AWS CloudTrail logs, see [Identifying access to S3 objects by using CloudTrail](#).

Monitoring metrics with Amazon CloudWatch

Amazon CloudWatch metrics for Amazon S3 can help you understand and improve the performance of applications that use Amazon S3. There are several ways that you can use CloudWatch with Amazon S3.

Daily storage metrics for buckets

Monitor bucket storage using CloudWatch, which collects and processes storage data from Amazon S3 into readable, daily metrics. These storage metrics for Amazon S3 are reported once per day and are provided to all customers at no additional cost.

Request metrics

Monitor Amazon S3 requests to quickly identify and act on operational issues. The metrics are available at 1-minute intervals after some latency for processing. These CloudWatch metrics are billed at the same rate as the Amazon CloudWatch custom metrics. For information about CloudWatch pricing, see [Amazon CloudWatch pricing](#). To learn how to opt in to getting these metrics, see [CloudWatch metrics configurations](#).

When enabled, request metrics are reported for all object operations. By default, these 1-minute metrics are available at the Amazon S3 bucket level. You can also define a filter for the metrics using a shared prefix, object tag, or access point:

- **Access point** – Access points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. With the access point filter, you can gain insights into your access point usage. For more information about access points, see [Monitoring and logging access points](#).
- **Prefix** – Although the Amazon S3 data model is a flat structure, you can use prefixes to infer a hierarchy. A prefix is similar to a directory name that enables you to group similar objects together in a bucket. The S3 console supports prefixes with the concept of folders. If you

filter by prefix, objects that have the same prefix are included in the metrics configuration.

For more information about prefixes, see [Organizing objects using prefixes](#).

- **Tags** – Tags are key-value name pairs that you can add to objects. Tags help you find and organize objects easily. You can also use tags as a filter for metrics configurations so that only objects with those tags are included in the metrics configuration. For more information about object tags, see [Categorizing your storage using tags](#).

To align these metrics to specific business applications, workflows, or internal organizations, you can filter on a shared prefix, object tag, or access point.

Replication metrics

Replication metrics – Monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination AWS Region, and the total number of operations that failed replication. Replication rules that have S3 Replication Time Control (S3 RTC) or S3 Replication metrics enabled will publish replication metrics.

For more information, see [Monitoring progress with replication metrics and S3 Event Notifications](#) or [Meeting compliance requirements using S3 Replication Time Control \(S3 RTC\)](#).

Amazon S3 Storage Lens metrics

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). S3 Storage Lens metrics are available in the AWS/S3/Storage-Lens namespace. The CloudWatch publishing option is available for S3 Storage Lens dashboards upgraded to *advanced metrics and recommendations*. You can enable the CloudWatch publishing option for a new or existing dashboard configuration in S3 Storage Lens.

For more information, see [Monitor S3 Storage Lens metrics in CloudWatch](#).

All CloudWatch statistics are retained for a period of 15 months so that you can access historical information and gain a better perspective on how your web application or service is performing.

For more information about CloudWatch, see [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*. You may need some additional configurations to your CloudWatch alarms, depending on your use cases. For example, you can use metric math expression to create an alarm. For more information, see [Use CloudWatch metrics](#), [Use metric math](#), [Using Amazon CloudWatch alarms](#), and [Create a CloudWatch alarm based on a metric math expression](#) in the *Amazon CloudWatch User Guide*.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the [Billing & Cost Management Dashboard](#) might include one or more access requests that do not appear in the bucket metrics.

For more information, see the following topics.

Topics

- [Metrics and dimensions](#)

Amazon S3 daily storage metrics for buckets in CloudWatch

The AWS/S3 namespace includes the following daily storage metrics for buckets.

Metric	Description
BucketSizeBytes	<p>The amount of data in bytes that is stored in a bucket in the following storage classes:</p> <ul style="list-style-type: none">• S3 Standard (STANDARD)• S3 Intelligent-Tiering (INTELLIGENT_TIERING)• S3 Standard-Infrequent Access (STANDARD_IA)• S3 One Zone-Infrequent Access (ONEZONE_IA)• Reduced Redundancy Storage (RRS) (REDUCED_REDUNDANCY)• S3 Glacier Instant Retrieval (GLACIER_IR)• S3 Glacier Deep Archive (DEEP_ARCHIVE)• S3 Glacier Flexible Retrieval (GLACIER)

Metric	Description
	<ul style="list-style-type: none">• S3 Express One Zone (EXPRESS_ONEZONE) <p>This value is calculated by summing the size of all objects and metadata in the bucket (both current and noncurrent objects), including the size of all parts for all incomplete multipart uploads to the bucket.</p> <p>Valid storage-type filters: StandardStorage , IntelligentTieringFAStorage , IntelligentTieringIAStorage , IntelligentTieringAAStorage , IntelligentTieringAIAStorage , IntelligentTieringDAAStrage , StandardIAStorage , StandardIASizeOverhead , StandardIAObjectOverhead , OneZoneIAStorage , OneZoneIASizeOverhead , ReducedRedundancyStorage , GlacierInstantRetrievalSizeOverhead , GlacierInstantRetrievalStorage , GlacierStorage , GlacierStagingStorage , GlacierObjectOverhead , GlacierS3ObjectOverhead , DeepArchiveStorage , DeepArchiveObjectOverhead , DeepArchiveS3ObjectOverhead , DeepArchiveStagingStorage , and ExpressOneZone (see the StorageType dimension)</p> <p>Units: Bytes</p> <p>Valid statistics: Average</p>

Metric	Description
NumberOfObjects	<p>The total number of objects stored in a general purpose bucket for all storage classes. This value is calculated by counting all objects in the bucket, which includes current and noncurrent objects, delete markers, and the total number of parts for all incomplete multipart uploads to the bucket. For directory buckets with objects in the S3 Express One Zone storage class, this value is calculated by counting all objects in the bucket, but it doesn't include incomplete multiple uploads to the bucket.</p> <p>Valid storage type filters: AllStorageTypes (see the StorageType dimension)</p> <p>Units: Count</p> <p>Valid statistics: Average</p>

Amazon S3 request metrics in CloudWatch

The AWS/S3 namespace includes the following request metrics. These metrics include non-billable requests (in the case of GET requests from CopyObject and Replication).

 **Note**

Amazon S3 request metrics in CloudWatch aren't supported for directory buckets.

Metric	Description
AllRequests	<p>The total number of HTTP requests made to an Amazon S3 bucket, regardless of type. If you're using a metrics configuration with a filter, then this metric returns only the HTTP requests that meet the filter's requirements.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
GetRequests	<p>The number of HTTP GET requests made for objects in an Amazon S3 bucket. This doesn't include list operations. This metric is incremented for the source of each <code>CopyObject</code> request.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p> Note</p><p>Paginated list-oriented requests, such as ListMultipartUploads, ListParts, ListObjectVersions, and others, are not included in this metric.</p></div>
PutRequests	<p>The number of HTTP PUT requests made for objects in an Amazon S3 bucket. This metric is incremented for the destination of each <code>CopyObject</code> request.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
DeleteRequests	<p>The number of HTTP DELETE requests made for objects in an Amazon S3 bucket. This metric also includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
HeadRequests	<p>The number of HTTP HEAD requests made to an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
PostRequests	<p>The number of HTTP POST requests made to an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p>Note</p><p>DeleteObjects and SelectObjectContent requests are not included in this metric.</p></div>
SelectRequests	<p>The number of Amazon S3 SelectObjectContent requests made for objects in an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
SelectBytesScanned	<p>The number of bytes of data scanned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
SelectBytesReturned	<p>The number of bytes of data returned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
ListRequests	<p>The number of HTTP requests that list the contents of a bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
BytesDownloaded	<p>The number of bytes downloaded for requests made to an Amazon S3 bucket, where the response includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
BytesUploaded	<p>The number of bytes uploaded for requests made to an Amazon S3 bucket, where the request includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
4xxErrors	<p>The number of HTTP 4xx client error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>

Metric	Description
5xxErrors	<p>The number of HTTP 5xx server error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
FirstByteLatency	<p>The per-request time from the complete request being received by an Amazon S3 bucket to when the response starts to be returned.</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
TotalRequestLatency	<p>The elapsed per-request time from the first byte received to the last byte sent to an Amazon S3 bucket. This metric includes the time taken to receive the request body and send the response body, which is not included in FirstByteLatency .</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>

S3 Replication metrics in CloudWatch

You can monitor the progress of replication with S3 Replication metrics by tracking bytes pending, operations pending, and replication latency. For more information, see [Monitoring progress with replication metrics](#).

Note

You can enable alarms for your replication metrics in Amazon CloudWatch. When you set up alarms for your replication metrics, set the **Missing data treatment** field to **Treat missing data as ignore (maintain the alarm state)**.

Metric	Description
ReplicationLatency	<p>The maximum number of seconds by which the replication destination AWS Region is behind the source AWS Region for a given replication rule.</p> <p>Units: Seconds</p> <p>Valid statistics: Max</p>
BytesPendingReplication	<p>The total number of bytes of objects pending replication for a given replication rule.</p> <p>Units: Bytes</p> <p>Valid statistics: Max</p>
OperationsPendingReplication	<p>The number of operations pending replication for a given replication rule.</p> <p>Units: Count</p> <p>Valid statistics: Max</p>
OperationsFailedReplication	<p>The number of operations that failed to replicate for a given replication rule.</p> <p>Units: Count</p> <p>Valid statistics: Sum (total number of failed operations), Average (failure rate), Sample Count (total number of replication operations)</p>

S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). S3 Storage Lens metrics are published to the AWS/S3/Storage-Lens namespace in CloudWatch. The CloudWatch publishing option is available for S3 Storage Lens dashboards that have been upgraded to advanced metrics and recommendations.

For a list of S3 Storage Lens metrics that are published to CloudWatch, see [Amazon S3 Storage Lens metrics glossary](#). For a complete list of dimensions, see [Dimensions](#).

S3 Object Lambda request metrics in CloudWatch

S3 Object Lambda includes the following request metrics.

Metric	Description
AllRequests	<p>The total number of HTTP requests made to an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
GetRequests	<p>The number of HTTP GET requests made for objects by using an Object Lambda Access Point. This metric does not include list operations.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
BytesUploaded	<p>The number of bytes uploaded to an Amazon S3 bucket by using an Object Lambda Access Point, where the request includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
PostRequests	<p>The number of HTTP POST requests made to an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
PutRequests	<p>The number of HTTP PUT requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
DeleteRequests	<p>The number of HTTP DELETE requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point. This metric includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
BytesDownloaded	<p>The number of bytes downloaded for requests made to an Amazon S3 bucket by using an Object Lambda Access Point, where the response includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
FirstByteLatency	<p>The per-request time from the complete request being received by an Amazon S3 bucket through an Object Lambda Access Point to when the response starts to be returned. This metric is dependent on the AWS Lambda function's running time to transform the object before the function returns the bytes to the Object Lambda Access Point.</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
TotalRequestLatency	<p>The elapsed per-request time from the first byte received to the last byte sent to an Object Lambda Access Point. This metric includes the time taken to receive the request body and send the response body, which is not included in FirstByteLatency .</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
HeadRequests	<p>The number of HTTP HEAD requests made to an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
ListRequests	<p>The number of HTTP GET requests that list the contents of an Amazon S3 bucket. This metric includes both ListObjects and ListObjectsV2 operations.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
4xxErrors	<p>The number of HTTP 4xx server error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
5xxErrors	<p>The number of HTTP 5xx server error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
ProxiedRequests	<p>The number of HTTP requests to an Object Lambda Access Point that return the standard Amazon S3 API response. (Such requests do not have a Lambda function configured.)</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
InvokedLambda	<p>The number of HTTP requests to an S3 object where a Lambda function was invoked.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
LambdaResponseRequests	The number of <code>WriteGetObjectResponse</code> requests made by the Lambda function. This metric applies only to <code>GetObject</code> requests.
LambdaResponse4xx	The number of HTTP 4xx client errors that occur when calling <code>WriteGetObjectResponse</code> from a Lambda function. This metric provides the same information as <code>4xxErrors</code> , but only for <code>WriteGetObjectResponse</code> calls.
LambdaResponse5xx	The number of HTTP 5xx server errors that occur when calling <code>WriteGetObjectResponse</code> from a Lambda function. This metric provides the same information as <code>5xxErrors</code> , but only for <code>WriteGetObjectResponse</code> calls.

Amazon S3 on Outposts metrics in CloudWatch

For a list of metrics in CloudWatch that are used for S3 on Outposts buckets, see [CloudWatch metrics](#).

Amazon S3 dimensions in CloudWatch

The following dimensions are used to filter Amazon S3 metrics.

Dimension	Description
BucketName	This dimension filters the data that you request for the identified bucket only.
StorageType	This dimension filters the data that you have stored in a bucket by the following types of storage: <ul style="list-style-type: none"> <code>StandardStorage</code> – The number of bytes used for objects in the STANDARD storage class. <code>IntelligentTieringAAStorage</code> – The number of bytes used for objects in the Archive Access tier of the INTELLIGENT_TIERING storage class.

Dimension	Description
	<ul style="list-style-type: none"> • IntelligentTieringAIAStorage – The number of bytes used for objects in the Archive Instant Access tier of the INTELLIGENT_TIERING storage class. • IntelligentTieringDAAStorage – The number of bytes used for objects in the Deep Archive Access tier of the INTELLIGENT_TIERING storage class. • IntelligentTieringFAStorage – The number of bytes used for objects in the Frequent Access tier of the INTELLIGENT_TIERING storage class. • IntelligentTieringIAStorage – The number of bytes used for objects in the Infrequent Access tier of the INTELLIGENT_TIERING storage class. • StandardIAStorage – The number of bytes used for objects in the S3 Standard-Infrequent Access (STANDARD_IA) storage class. • StandardIASizeOverhead – The number of bytes used for objects smaller than 128 KB in the STANDARD_IA storage class. • IntAAObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Archive Access tier, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage. • IntAAS3ObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Archive Access tier, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage. • IntDAAObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Deep Archive Access tier, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to

You are charged S3 Standard rates for this additional storage. • DeepArchiveStagingStorage – The number of bytes used for parts of multipart objects before the <code>CompleteMultipartUpload</code> request is completed on objects in the S3 Glacier Deep Archive storage class. • ExpressOneZone – The number of bytes used for objects in the S3 Express One Zone storage class.
FilterId	<p>This dimension filters metrics configurations that you specify for the request metrics on a bucket. When you create a metrics configuration, you specify a filter ID (for example, a prefix, a tag, or an access point). For more information, see Creating a metrics configuration.</p>

S3 Replication dimensions in CloudWatch

The following dimensions are used to filter S3 Replication metrics.

Dimension	Description
SourceBucket	The name of the bucket objects are replicated from.
DestinationBucket	The name of the bucket objects are replicated to.
RuleId	A unique identifier for the rule that triggered this replication metric to update.

S3 Storage Lens dimensions in CloudWatch

For a list of dimensions that are used to filter S3 Storage Lens metrics in CloudWatch, see [Dimensions](#).

S3 Object Lambda request dimensions in CloudWatch

The following dimensions are used to filter data from an Object Lambda Access Point.

Dimension	Description
AccessPointName	The name of the access point of which requests are being made.
DataSourceARN	The source the Object Lambda Access Point is retrieving the data from. If the request invokes a Lambda function this refers to the Lambda Amazon Resource Name (ARN). Otherwise this refers to the access point ARN.

Accessing CloudWatch metrics

You can use the following procedures to view the storage metrics for Amazon S3. To get the Amazon S3 metrics involved, you must set a start and end timestamp. For metrics for any given 24-hour period, set the time period to 86400 seconds, the number of seconds in a day. Also, remember to set the BucketName and StorageType dimensions.

Using the AWS CLI

For example, if you want to use the AWS CLI to get the average of a specific bucket's size in bytes, you could use the following command:

```
aws cloudwatch get-metric-statistics --metric-name BucketSizeBytes --namespace AWS/S3  
--start-time 2016-10-19T00:00:00Z --end-time 2016-10-20T00:00:00Z --statistics Average  
--unit Bytes --region us-west-2 --dimensions Name=BucketName,Value=DOC-EXAMPLE-BUCKET  
Name=StorageType,Value=StandardStorage --period 86400 --output json
```

This example produces the following output.

```
{  
    "Datapoints": [  
        {  
            "Timestamp": "2016-10-19T00:00:00Z",  
            "Average": 1025328.0,  
            "Unit": "Bytes"  
        }  
    ],  
    "Label": "BucketSizeBytes"  
}
```

Using the S3 console

To view metrics by using the Amazon CloudWatch console

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the left navigation pane, choose **Metrics**.
3. Choose the **S3** namespace.
4. (Optional) To view a metric, enter the metric name in the search box.
5. (Optional) To filter by the **StorageType** dimension, enter the name of the storage class in the search box.

To view a list of valid metrics stored for your AWS account by using the AWS CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace "AWS/S3"
```

For more information about the permissions required to access CloudWatch dashboards, see [Amazon CloudWatch dashboard permissions](#) in the *Amazon CloudWatch User Guide*.

CloudWatch metrics configurations

With Amazon CloudWatch request metrics for Amazon S3, you can receive 1-minute CloudWatch metrics, set CloudWatch alarms, and access CloudWatch dashboards to view near-real-time operations and performance of your Amazon S3 storage. For applications that depend on cloud storage, these metrics let you quickly identify and act on operational issues. When enabled, these 1-minute metrics are available at the Amazon S3 bucket-level, by default.

If you want to get the CloudWatch request metrics for the objects in a bucket, you must create a metrics configuration for the bucket. For more information, see [Creating a CloudWatch metrics configuration for all the objects in your bucket](#).

You can also use a shared prefix, object tags, or an access point to define a filter for the metrics collected. This method of defining a filter allows you to align metrics filters to specific business applications, workflows, or internal organizations. For more information, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#). For more information about the CloudWatch metrics that are available and the differences between storage and request metrics, see [Monitoring metrics with Amazon CloudWatch](#).

Keep the following in mind when using metrics configurations:

- You can have a maximum of 1,000 metrics configurations per bucket.
- You can choose which objects in a bucket to include in metrics configurations by using filters. You can filter on a shared prefix, object tag, or access point to align metrics filters to specific business applications, workflows, or internal organizations. To request metrics for the entire bucket, create a metrics configuration without a filter.
- Metrics configurations are necessary only to enable request metrics. Bucket-level daily storage metrics are always turned on, and are provided at no additional cost. Currently, it's not possible to get daily storage metrics for a filtered subset of objects.
- Each metrics configuration enables the full set of [available request metrics](#). Operation-specific metrics (such as PostRequests) are reported only if there are requests of that type for your bucket or your filter.
- Request metrics are reported for object-level operations. They are also reported for operations that list bucket contents, like [GET Bucket \(List Objects\)](#), [GET Bucket Object Versions](#), and [List Multipart Uploads](#), but they are not reported for other operations on buckets.
- Request metrics support filtering by prefix, object tags, or access point, but storage metrics do not.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the [Billing & Cost Management Dashboard](#) might include one or more access requests that do not appear in the bucket metrics.

For more information about working with CloudWatch metrics in Amazon S3, see the following topics.

Topics

- [Creating a CloudWatch metrics configuration for all the objects in your bucket](#)
- [Creating a metrics configuration that filters by prefix, object tag, or access point](#)
- [Deleting a metrics filter](#)

Creating a CloudWatch metrics configuration for all the objects in your bucket

When you configure request metrics, you can create a CloudWatch metrics configuration for all the objects in your bucket, or you can filter by prefix, object tag, or access point. The procedures in this topic show you how to create a configuration for all the objects in your bucket. To create a configuration that filters by object tag, prefix, or access point, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#).

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. [S3 Replication](#)

[metrics](#) provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

You can add metrics configurations to a bucket using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the objects you want request metrics for.
3. Choose the **Metrics** tab.
4. Under **Bucket metrics**, choose **View additional charts**.
5. Choose the **Request metrics** tab.
6. Choose **Create filter**.
7. In the **Filter name** box, enter your filter name.

Names can only contain letters, numbers, periods, dashes, and underscores. We recommend using the name `EntireBucket` for a filter that applies to all objects.

8. Under **Filter scope**, choose **This filter applies to all objects in the bucket**.

You can also define a filter so that the metrics are only collected and reported on a subset of objects in the bucket. For more information, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#).

9. Choose **Save changes**.
10. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

After about 15 minutes, CloudWatch begins tracking these request metrics. You can see them on the **Request metrics** tab. You can see graphs for the metrics on the Amazon S3 or CloudWatch console. Request metrics are billed at the standard CloudWatch rate. For more information, see [Amazon CloudWatch pricing](#).

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see [Installing, updating, and uninstalling the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. Run the following command to add a metrics configuration.

```
aws s3api put-bucket-metrics-configuration --endpoint https://s3.us-west-2.amazonaws.com --bucket bucket-name --id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'}'
```

Creating a metrics configuration that filters by prefix, object tag, or access point

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. [S3 Replication metrics](#) provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

When you configure CloudWatch metrics, you can create a filter for all the objects in your bucket, or you can filter the configuration into groups of related objects within a single bucket. You can filter objects in a bucket for inclusion in a metrics configuration based on one or more of the following filter types:

- **Object key name prefix** – Although the Amazon S3 data model is a flat structure, you can infer a hierarchy by using a prefix. The Amazon S3 console supports these prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see [Organizing objects using prefixes](#).
- **Tag** – You can add tags, which are key-value name pairs, to objects. Tags help you find and organize objects easily. You can also use tags as filters for metrics configurations. For more information about object tags, see [Categorizing your storage using tags](#).
- **Access point** – S3 Access Points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. When you create an access point filter, Amazon S3 includes requests to the access point that you specify in the metrics configuration. For more information, see [Monitoring and logging access points](#).

 **Note**

When you create a metrics configuration that filters by access point, you must use the access point Amazon Resource Name (ARN), not the access point alias. Make sure that you use the ARN for the access point itself, not the ARN for a specific object. For more information about access point ARNs, see [Using access points](#).

If you specify a filter, only requests that operate on single objects can match the filter and be included in the reported metrics. Requests like [DeleteObjects](#) and [ListObjects](#) requests don't return any metrics for configurations with filters.

To request more complex filtering, choose two or more elements. Only objects that have all of those elements are included in the metrics configuration. If you don't set filters, all of the objects in the bucket are included in the metrics configuration.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the **Buckets** list, choose the name of the bucket that contains the objects that you want request metrics for.
3. Choose the **Metrics** tab.
4. Under **Bucket metrics**, choose **View additional charts**.
5. Choose the **Request metrics** tab.
6. Choose **Create filter**.
7. In the **Filter name** box, enter your filter name.

Names can contain only letters, numbers, periods, dashes, and underscores.
8. Under **Filter scope**, choose **Limit the scope of this filter using a prefix, object tags, and an S3 Access Point, or a combination of all three**.
9. Under **Filter type**, choose at least one filter type: **Prefix**, **Object tags**, or **Access Point**.
10. To define a prefix filter and limit the scope of the filter to a single path, in the **Prefix** box, enter a prefix.
11. To define an object tags filter, under **Object tags**, choose **Add tag**, and then enter a tag **Key** and **Value**.
12. To define an access point filter, in the **S3 Access Point** field, enter the access point ARN, or choose **Browse S3** to navigate to the access point.

⚠ Important

You cannot enter an access point alias. You must enter the ARN for the access point itself, not the ARN for a specific object.

13. Choose **Save changes**.

Amazon S3 creates a filter that uses the prefix, tags, or access point that you specified.

14. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

You have now created a filter that limits the request metrics scope by prefix, object tags, or access point. About 15 minutes after CloudWatch begins tracking these request metrics, you can see charts for the metrics on both the Amazon S3 and CloudWatch consoles. Request metrics are billed at the standard CloudWatch rate. For more information, see [Amazon CloudWatch pricing](#).

You can also configure request metrics at the bucket level. For information, see [Creating a CloudWatch metrics configuration for all the objects in your bucket](#).

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see [Installing, updating, and uninstalling the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. To add a metrics configuration, run one of the following commands:

Example : To filter by prefix

```
aws s3api put-bucket-metrics-configuration --bucket DOC-EXAMPLE-BUCKET1 --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"Prefix":"'prefix1'"}' '
```

Example : To filter by tags

```
aws s3api put-bucket-metrics-configuration --bucket DOC-EXAMPLE-BUCKET1 --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"Tag": {"Key": "string", "Value": "string"} }' '
```

Example : To filter by access point

```
aws s3api put-bucket-metrics-configuration --bucket DOC-EXAMPLE-BUCKET1 --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"AccessPointArn":":arn:aws:s3:Region:account-id:accesspoint/access-point-name"} }' '
```

Example : To filter by prefix, tags, and access point

```
aws s3api put-bucket-metrics-configuration --endpoint https://  
s3.Region.amazonaws.com --bucket DOC-EXAMPLE-BUCKET1 --id metrics-config-id --  
metrics-configuration '  
{  
    "Id": "metrics-config-id",  
    "Filter": {  
        "And": {  
            "Prefix": "string",  
            "Tag": {"Key": "string", "Value": "string"}  
        }  
    }  
}'
```

```
"Tags": [  
    {  
        "Key": "string",  
        "Value": "string"  
    }  
,  
    "AccessPointArn": "arn:aws:s3:Region:account-id:accesspoint/access-point-name"  
}  
}  
}'
```

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Deleting a metrics filter

You can delete an Amazon CloudWatch request metrics filter if you no longer need it. When you delete a filter, you are no longer charged for request metrics that use that *specific filter*. However, you will continue to be charged for any other filter configurations that exist.

When you delete a filter, you can no longer use the filter for request metrics. Deleting a filter cannot be undone.

For information about creating a request metrics filter, see the following topics:

- [Creating a CloudWatch metrics configuration for all the objects in your bucket](#)
- [Creating a metrics configuration that filters by prefix, object tag, or access point](#)

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose your bucket name.
3. Choose the **Metrics** tab.
4. Under **Bucket metrics**, choose **View additional charts**.
5. Choose the **Request metrics** tab.
6. Choose **Manage filters**.
7. Choose your filter.

 **Important**

Deleting a filter cannot be undone.

8. Choose **Delete**.

Amazon S3 deletes your filter.

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Amazon S3 Event Notifications

You can use the Amazon S3 Event Notifications feature to receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that identifies the events that you want Amazon S3 to publish. Make sure that it also identifies the

destinations where you want Amazon S3 to send the notifications. You store this configuration in the *notification* subresource that's associated with a bucket. For more information, see [Bucket configuration options](#). Amazon S3 provides an API for you to manage this subresource.

 **Important**

Amazon S3 event notifications are designed to be delivered at least once. Typically, event notifications are delivered in seconds but can sometimes take a minute or longer.

Overview of Amazon S3 Event Notifications

Currently, Amazon S3 can publish notifications for the following events:

- New object created events
- Object removal events
- Restore object events
- Reduced Redundancy Storage (RRS) object lost events
- Replication events
- S3 Lifecycle expiration events
- S3 Lifecycle transition events
- S3 Intelligent-Tiering automatic archival events
- Object tagging events
- Object ACL PUT events

For full descriptions of all the supported event types, see [Supported event types for SQS, SNS, and Lambda](#).

Amazon S3 can send event notification messages to the following destinations. You specify the Amazon Resource Name (ARN) value of these destinations in the notification configuration.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda function

- Amazon EventBridge

For more information, see [Supported event destinations](#).

 **Note**

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

 **Warning**

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.

For more information and an example of using Amazon S3 notifications with AWS Lambda, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

For more information about the number of event notification configurations that you can create per bucket, see [Amazon S3 service quotas](#) in *AWS General Reference*.

For more information about event notifications, see the following sections.

Topics

- [Event notification types and destinations](#)
- [Using Amazon SQS, Amazon SNS, and Lambda](#)
- [Using EventBridge](#)

Event notification types and destinations

Amazon S3 supports several event notification types and destinations where the notifications can be published. You can specify the event type and destination when configuring your event

notifications. Only one destination can be specified for each event notification. Amazon S3 event notifications send one event entry for each notification message.

Topics

- [Supported event destinations](#)
- [Supported event types for SQS, SNS, and Lambda](#)
- [Supported event types for Amazon EventBridge](#)

Supported event destinations

Amazon S3 can send event notification messages to the following destinations.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda
- Amazon EventBridge

However, only one destination type can be specified for each event notification.

Note

You must grant Amazon S3 permissions to post messages to an Amazon SNS topic or an Amazon SQS queue. You must also grant Amazon S3 permission to invoke an AWS Lambda function on your behalf. For instructions on how to grant these permissions, see [Granting permissions to publish event notification messages to a destination](#).

Amazon SNS topic

Amazon SNS is a flexible, fully managed push messaging service. You can use this service to push messages to mobile devices or distributed services. With SNS, you can publish a message once, and deliver it one or more times. Currently, Standard SNS is only allowed as an S3 event notification destination, whereas SNS FIFO is not allowed.

Amazon SNS both coordinates and manages sending and delivering messages to subscribing endpoints or clients. You can use the Amazon SNS console to create an Amazon SNS topic that your notifications can be sent to.

The topic must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SNS topic, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide* and the [Amazon SNS FAQ](#).

Before you can use the Amazon SNS topic that you created as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SNS topic
- A valid Amazon SNS topic subscription. With it, topic subscribers are notified when a message is published to your Amazon SNS topic.

Amazon SQS queue

Amazon SQS offers reliable and scalable hosted queues for storing messages as they travel between computers. You can use Amazon SQS to transmit any volume of data without requiring other services to be always available. You can use the Amazon SQS console to create an Amazon SQS queue that your notifications can be sent to.

The Amazon SQS queue must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SQS queue, see [What is Amazon Simple Queue Service](#) and [Getting started with Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*.

Before you can use the Amazon SQS queue as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SQS queue

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Lambda function

You can use AWS Lambda to extend other AWS services with custom logic, or create your own backend that operates at AWS scale, performance, and security. With Lambda, you can create

discrete, event-driven applications that run only when needed. You can also use it to scale these applications automatically from a few requests a day to thousands a second.

Lambda can run custom code in response to Amazon S3 bucket events. You upload your custom code to Lambda and create what's called a Lambda function. When Amazon S3 detects an event of a specific type, it can publish the event to AWS Lambda and invoke your function in Lambda. In response, Lambda runs your function. One event type it might detect, for example, is an object created event.

You can use the AWS Lambda console to create a Lambda function that uses the AWS infrastructure to run the code on your behalf. The Lambda function must be in the same Region as your S3 bucket. You must also have the name or the ARN of a Lambda function to set up the Lambda function as an event notification destination.

Warning

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.

For more information and an example of using Amazon S3 notifications with AWS Lambda, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Amazon EventBridge

Amazon EventBridge is a serverless event bus, which receives events from AWS services. You can set up rules to match events and deliver them to targets, such as an AWS service or an HTTP endpoint. For more information, see [What is EventBridge](#) in the *Amazon EventBridge User Guide*.

Unlike other destinations, you can either enable or disable events to be delivered to EventBridge for a bucket. If you enable delivery, all events are sent to EventBridge. Moreover, you can use EventBridge rules to route events to additional targets.

Supported event types for SQS, SNS, and Lambda

Amazon S3 can publish events of the following types. You specify these event types in the notification configuration.

Event types	Description
<i>s3:TestEvent</i>	<p>When a notification is enabled, Amazon S3 publishes a test notification. This is to ensure that the topic exists and that the bucket owner has permission to publish the specified topic.</p> <p>If enabling the notification fails, you don't receive a test notification.</p>
<i>s3:ObjectCreated:*</i> <i>s3:ObjectCreated:Put</i> <i>s3:ObjectCreated:Post</i> <i>s3:ObjectCreated:Copy</i> <i>s3:ObjectCreated:CompleteMultipartUpload</i>	<p>Amazon S3 API operations such as PUT, POST, and COPY can create an object. With these event types, you can enable notifications when an object is created using a specific API operation. Alternatively, you can use the <i>s3:ObjectCreated:*</i> event type to request notification regardless of the API that was used to create an object.</p> <p><i>s3:ObjectCreated:CompleteMultipartUpload</i> includes objects that are created using UploadPartCopy for Copy operations.</p>
<i>s3:ObjectRemoved:*</i> <i>s3:ObjectRemoved:Delete</i> <i>s3:ObjectRemoved:DeleteMarkerCreated</i>	<p>By using the <i>ObjectRemoved</i> event types, you can enable notification when an object or a batch of objects is removed from a bucket.</p> <p>You can request notification when an object is deleted or a versioned object is permanently deleted by using the <i>s3:ObjectRemoved:Delete</i> event type. Alternatively, you can request notification when a delete marker is created for a versioned object using <i>s3:ObjectRemoved:DeleteMarkerCreated</i>. For instructions on how to delete versioned objects, see Deleting object versions from a versioning-enabled bucket. You can also use a wildcard <i>s3:ObjectRemoved:*</i> to request notification anytime an object is deleted.</p>

Event types	Description
	These event notifications don't alert you for automatic deletes from lifecycle configurations or from failed operations.
<i>s3:ObjectRestore:*</i> <i>s3:ObjectRestore:Post</i> <i>s3:ObjectRestore:Completed</i> <i>s3:ObjectRestore:Delete</i>	By using the <i>ObjectRestore</i> event types, you can receive notifications for event initiation and completion when restoring objects from the S3 Glacier Flexible Retrieval storage class, S3 Glacier Deep Archive storage class, S3 Intelligent-Tiering Archive Access tier, and S3 Intelligent-Tiering Deep Archive Access tier. You can also receive notifications for when the restored copy of an object expires.
	The <i>s3:ObjectRestore:Post</i> event type notifies you of object restoration initiation. The <i>s3:ObjectRestore:Completed</i> event type notifies you of restoration completion. The <i>s3:ObjectRestore:Delete</i> event type notifies you when the temporary copy of a restored object expires.
<i>s3:ReducedRedundancyLostObject</i>	You receive this notification event when Amazon S3 detects that an object of the RRS storage class is lost.

Event types	Description
<p><i>s3:Replication:*</i></p> <p><i>s3:Replication:OperationFailedReplication</i></p> <p><i>s3:Replication:OperationMissedThreshold</i></p> <p><i>s3:Replication:OperationReplicatedAfterThreshold</i></p> <p><i>s3:Replication:OperationNotTracked</i></p>	<p>By using the <i>Replication</i> event types, you can receive notifications for replication configurations that have S3 Replication metrics or S3 Replication Time Control (S3 RTC) enabled. You can monitor the minute-by-minute progress of replication events by tracking bytes pending, operations pending, and replication latency. For information about replication metrics, see Monitoring progress with replication metrics and S3 Event Notifications</p> <p>The <i>s3:Replication:OperationFailedReplication</i> event type notifies you when an object that was eligible for replication failed to replicate. The <i>s3:Replication:OperationMissedThreshold</i> event type notifies you when an object that was eligible for replication exceeds the 15-minute threshold for replication.</p> <p>The <i>s3:Replication:OperationReplicatedAfterThreshold</i> event type notifies you when an object that was eligible for replication that uses S3 Replication Time Control replicates after the 15-minute threshold. The <i>s3:Replication:OperationNotTracked</i> event type notifies you when an object that was eligible for replication that uses S3 Replication Time Control but is no longer tracked by replication metrics.</p>

Event types	Description
<i>s3:LifecycleExpiration:*</i>	By using the <i>LifecycleExpiration</i> event types, you can receive a notification when Amazon S3 deletes an object based on your S3 Lifecycle configuration.
<i>s3:LifecycleExpiration:Delete</i>	
<i>s3:LifecycleExpiration:DeleteMarkerCreated</i>	The <i>s3:LifecycleExpiration:Delete</i> event type notifies you when an object in an unversioned bucket is deleted. It also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration. The <i>s3:LifecycleExpiration:DeleteMarkerCreated</i> event type notifies you when S3 Lifecycle creates a delete marker when a current version of an object in versioned bucket is deleted.
<i>s3:LifecycleTransition</i>	You receive this notification event when an object is transitioned to another Amazon S3 storage class by an S3 Lifecycle configuration.
<i>s3:IntelligentTiering</i>	You receive this notification event when an object within the S3 Intelligent-Tiering storage class moved to the Archive Access tier or Deep Archive Access tier.
<i>s3:ObjectTagging:*</i>	By using the <i>ObjectTagging</i> event types, you can enable notification when an object tag is added or deleted from an object.
<i>s3:ObjectTagging:Put</i>	
<i>s3:ObjectTagging:Delete</i>	The <i>s3:ObjectTagging:Put</i> event type notifies you when a tag is PUT on an object or an existing tag is updated. The <i>s3:ObjectTagging:Delete</i> event type notifies you when a tag is removed from an object.
<i>s3:ObjectAcl:Put</i>	You receive this notification event when an ACL is PUT on an object or when an existing ACL is changed. An event is not generated when a request results in no change to an object's ACL.

Supported event types for Amazon EventBridge

For a list of event types Amazon S3 will send to Amazon EventBridge, see [Using EventBridge](#).

Using Amazon SQS, Amazon SNS, and Lambda

Enabling notifications is a bucket-level operation. You store notification configuration information in the *notification* subresource that's associated with a bucket. After you create or change the bucket notification configuration, it usually takes about five minutes for the changes to take effect. When the notification is first enabled, an s3:TestEvent occurs. You can use any of the following methods to manage notification configuration:

- **Using the Amazon S3 console** — You can use the console UI to set a notification configuration on a bucket without having to write any code. For more information, see [Enabling and configuring event notifications using the Amazon S3 console](#).
- **Programmatically using the AWS SDKs** — Internally, both the console and the SDKs call the Amazon S3 REST API to manage *notification* subresources that are associated with the bucket. For examples of notification configurations that use AWS SDK, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

 **Note**

You can also make the Amazon S3 REST API calls directly from your code. However, this can be cumbersome because to do so you must write code to authenticate your requests.

Regardless of the method that you use, Amazon S3 stores the notification configuration as XML in the *notification* subresource that's associated with a bucket. For information about bucket subresources, see [Bucket configuration options](#).

Topics

- [Granting permissions to publish event notification messages to a destination](#)
- [Enabling and configuring event notifications using the Amazon S3 console](#)
- [Configuring event notifications programmatically](#)
- [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#)
- [Configuring event notifications using object key name filtering](#)
- [Event message structure](#)

Granting permissions to publish event notification messages to a destination

You must grant the Amazon S3 principal the necessary permissions to call the relevant API to publish messages to an SNS topic, an SQS queue, or a Lambda function. This is so that Amazon S3 can publish event notification messages to a destination.

To troubleshoot publishing event notification messages to a destination, see [Troubleshoot to publish Amazon S3 event notifications to an Amazon Simple Notification Service topic](#).

Topics

- [Granting permissions to invoke an AWS Lambda function](#)
- [Granting permissions to publish messages to an SNS topic or an SQS queue](#)

Granting permissions to invoke an AWS Lambda function

Amazon S3 publishes event messages to AWS Lambda by invoking a Lambda function and providing the event message as an argument.

When you use the Amazon S3 console to configure event notifications on an Amazon S3 bucket for a Lambda function, the console sets up the necessary permissions on the Lambda function. This is so that Amazon S3 has permissions to invoke the function from the bucket. For more information, see [Enabling and configuring event notifications using the Amazon S3 console](#).

You can also grant Amazon S3 permissions from AWS Lambda to invoke your Lambda function. For more information, see [Tutorial: Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Granting permissions to publish messages to an SNS topic or an SQS queue

To grant Amazon S3 permissions to publish messages to the SNS topic or SQS queue, attach an AWS Identity and Access Management (IAM) policy to the destination SNS topic or SQS queue.

For an example of how to attach a policy to an SNS topic or an SQS queue, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#). For more information about permissions, see the following topics:

- [Example cases for Amazon SNS access control](#) in the *Amazon Simple Notification Service Developer Guide*
- [Identity and access management in Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*

IAM policy for a destination SNS topic

The following is an example of an AWS Identity and Access Management (IAM) policy that you attach to the destination SNS topic. For instructions on how to use this policy to set up a destination Amazon SNS topic for event notifications, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "Example SNS topic policy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "SNS:Publish"  
            ],  
            "Resource": "SNS-topic-ARN",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3::*:*:bucket-name"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "bucket-owner-account-id"  
                }  
            }  
        }  
    ]  
}
```

IAM policy for a destination SQS queue

The following is an example of an IAM policy that you attach to the destination SQS queue. For instructions on how to use this policy to set up a destination Amazon SQS queue for event notifications, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

To use this policy, you must update the Amazon SQS queue ARN, bucket name, and bucket owner's AWS account ID.

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "example-statement-ID",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "SQS:SendMessage"  
            ],  
            "Resource": "arn:aws:sqs:Region:account-id:queue-name",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:*.*:awsexamplebucket1"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "bucket-owner-account-id"  
                }  
            }  
        }  
    ]  
}
```

For both the Amazon SNS and Amazon SQS IAM policies, you can specify the `StringLike` condition in the policy instead of the `ArnLike` condition.

When `ArnLike` is used, the partition, service, account-id, resource-type, and partial resource-id portions of the ARN must have exact matching to the ARN in the request context. Only the region and resource path allow partial matching.

When `StringLike` is used instead of `ArnLike`, matching ignores the ARN structure and allows partial matching, regardless of the portion that was wildcarded. For more information, see [IAM JSON policy elements](#) in the *IAM User Guide*.

```
"Condition": {  
    "StringLike": { "aws:SourceArn": "arn:aws:s3:*.*:bucket-name" }  
}
```

AWS KMS key policy

If the SQS queue or SNS topics are encrypted with an AWS Key Management Service (AWS KMS) customer managed key, you must grant the Amazon S3 service principal permission to work with the encrypted topics or queue. To grant the Amazon S3 service principal permission, add the following statement to the key policy for the customer managed key.

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "example-statement-ID",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "kms:GenerateDataKey",  
                "kms:Decrypt"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

For more information about AWS KMS key policies, see [Using key policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

For more information about using server-side encryption with AWS KMS for Amazon SQS and Amazon SNS, see the following:

- [Key management](#) in the *Amazon Simple Notification Service Developer Guide*.
- [Key management](#) in the *Amazon Simple Queue Service Developer Guide*.
- [Encrypting messages published to Amazon SNS with AWS KMS](#) in the *AWS Compute Blog*.

Enabling and configuring event notifications using the Amazon S3 console

You can enable certain Amazon S3 bucket events to send a notification message to a destination whenever those events occur. This section explains how to use the Amazon S3 console to enable

event notifications. For information about how to use event notifications with the AWS SDKs and the Amazon S3 REST APIs, see [Configuring event notifications programmatically](#).

Prerequisites: Before you can enable event notifications for your bucket, you must set up one of the destination types and then configure permissions. For more information, see [Supported event destinations](#) and [Granting permissions to publish event notification messages to a destination](#).

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Topics

- [Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console](#)

Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console

To enable and configure event notifications for an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to enable events for.
3. Choose **Properties**.
4. Navigate to the **Event Notifications** section and choose **Create event notification**.
5. In the **General configuration** section, specify descriptive event name for your event notification. Optionally, you can also specify a prefix and a suffix to limit the notifications to objects with keys ending in the specified characters.
 - a. Enter a description for the **Event name**.
If you don't enter a name, a globally unique identifier (GUID) is generated and used for the name.
 - b. (Optional) To filter event notifications by prefix, enter a **Prefix**.

For example, you can set up a prefix filter so that you receive notifications only when files are added to a specific folder (for example, `images/`).

- c. (Optional) To filter event notifications by suffix, enter a **Suffix**.

For more information, see [Configuring event notifications using object key name filtering](#).

6. In the **Event types** section, select one or more event types that you want to receive notifications for.

For a list of the different event types, see [Supported event types for SQS, SNS, and Lambda](#).

7. In the **Destination** section, choose the event notification destination.

 **Note**

Before you can publish event notifications, you must grant the Amazon S3 principal the necessary permissions to call the relevant API. This is so that it can publish notifications to a Lambda function, SNS topic, or SQS queue.

- a. Select the destination type: **Lambda Function, SNS Topic, or SQS Queue**.
- b. After you choose your destination type, choose a function, topic, or queue from the list.
- c. Or, if you prefer to specify an Amazon Resource Name (ARN), select **Enter ARN** and enter the ARN.

For more information, see [Supported event destinations](#).

8. Choose **Save changes**, and Amazon S3 sends a test message to the event notification destination.

Configuring event notifications programmatically

By default, notifications aren't enabled for any type of event. Therefore, the *notification* subresource initially stores an empty configuration.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</NotificationConfiguration>
```

To enable notifications for events of specific types, you replace the XML with the appropriate configuration that identifies the event types you want Amazon S3 to publish and the destination where you want the events published. For each destination, you add a corresponding XML configuration.

To publish event messages to an SQS queue

To set an SQS queue as the notification destination for one or more event types, add the QueueConfiguration.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>optional-id-string</Id>
    <Queue>sqs-queue-arn</Queue>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </QueueConfiguration>
  ...
</NotificationConfiguration>
```

To publish event messages to an SNS topic

To set an SNS topic as the notification destination for specific event types, add the TopicConfiguration.

```
<NotificationConfiguration>
  <TopicConfiguration>
    <Id>optional-id-string</Id>
    <Topic>sns-topic-arn</Topic>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </TopicConfiguration>
  ...
</NotificationConfiguration>
```

To invoke the AWS Lambda function and provide an event message as an argument

To set a Lambda function as the notification destination for specific event types, add the CloudFunctionConfiguration.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
    <Id>optional-id-string</Id>
    <CloudFunction>cloud-function-arn</CloudFunction>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </CloudFunctionConfiguration>
  ...
</NotificationConfiguration>
```

To remove all notifications configured on a bucket

To remove all notifications configured on a bucket, save an empty `<NotificationConfiguration/>` element in the *notification* subresource.

When Amazon S3 detects an event of the specific type, it publishes a message with the event information. For more information, see [Event message structure](#).

For more information about configuring event notifications, see the following topics:

- [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).
- [Configuring event notifications using object key name filtering](#)

Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue)

You can receive Amazon S3 notifications using Amazon Simple Notification Service (Amazon SNS) or Amazon Simple Queue Service (Amazon SQS). In this walkthrough, you add a notification configuration to your bucket using an Amazon SNS topic and an Amazon SQS queue.

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Topics

- [Walkthrough summary](#)
- [Step 1: Create an Amazon SQS queue](#)
- [Step 2: Create an Amazon SNS topic](#)
- [Step 3: Add a notification configuration to your bucket](#)
- [Step 4: Test the setup](#)

Walkthrough summary

This walkthrough helps you do the following:

- Publish events of the s3:ObjectCreated:* type to an Amazon SQS queue.
- Publish events of the s3:ReducedRedundancyLostObject type to an Amazon SNS topic.

For information about notification configuration, see [Using Amazon SQS, Amazon SNS, and Lambda](#).

You can do all these steps using the console, without writing any code. In addition, code examples using AWS SDKs for Java and .NET are also provided to help you add notification configurations programmatically.

The procedure includes the following steps:

1. Create an Amazon SQS queue.

Using the Amazon SQS console, create an SQS queue. You can access any messages Amazon S3 sends to the queue programmatically. But, for this walkthrough, you verify notification messages in the console.

You attach an access policy to the queue to grant Amazon S3 permission to post messages.

2. Create an Amazon SNS topic.

Using the Amazon SNS console, create an SNS topic and subscribe to the topic. That way, any events posted to it are delivered to you. You specify email as the communications protocol. After you create a topic, Amazon SNS sends an email. You use the link in the email to confirm the topic subscription.

You attach an access policy to the topic to grant Amazon S3 permission to post messages.

3. Add notification configuration to a bucket.

Step 1: Create an Amazon SQS queue

Follow the steps to create and subscribe to an Amazon Simple Queue Service (Amazon SQS) queue.

1. Using the Amazon SQS console, create a queue. For instructions, see [Getting Started with Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*.
2. Replace the access policy that's attached to the queue with the following policy.
 - a. In the Amazon SQS console, in the **Queues** list, choose the queue name.
 - b. On the **Access policy** tab, choose **Edit**.
 - c. Replace the access policy that's attached to the queue. In it, provide your Amazon SQS ARN, source bucket name, and bucket owner account ID.

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "example-statement-ID",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "SQS:SendMessage"  
            ],  
            "Resource": "SQS-queue-ARN",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::awsexamplebucket1"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "bucket-owner-account-id"  
                }  
            }  
        }  
    ]  
}
```

- d. Choose **Save**.
3. (Optional) If the Amazon SQS queue or the Amazon SNS topic is server-side encryption enabled with AWS Key Management Service (AWS KMS), add the following policy to the associated symmetric encryption customer managed key.

You must add the policy to a customer managed key because you cannot modify the AWS managed key for Amazon SQS or Amazon SNS.

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "example-statement-ID",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "kms:GenerateDataKey",  
                "kms:Decrypt"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

For more information about using SSE for Amazon SQS and Amazon SNS with AWS KMS, see the following:

- [Key management in the Amazon Simple Notification Service Developer Guide](#).
- [Key management in the Amazon Simple Queue Service Developer Guide](#).

4. Note the queue ARN.

The SQS queue that you created is another resource in your AWS account. It has a unique Amazon Resource Name (ARN). You need this ARN in the next step. The ARN is of the following format:

`arn:aws:sqs:aws-region:account-id:queue-name`

Step 2: Create an Amazon SNS topic

Follow the steps to create and subscribe to an Amazon SNS topic.

1. Using Amazon SNS console, create a topic. For instructions, see [Creating an Amazon SNS topic](#) in the *Amazon Simple Notification Service Developer Guide*.
2. Subscribe to the topic. For this exercise, use email as the communications protocol. For instructions, see [Subscribing to an Amazon SNS topic](#) in the *Amazon Simple Notification Service Developer Guide*.

You get an email requesting you to confirm your subscription to the topic. Confirm the subscription.

3. Replace the access policy attached to the topic with the following policy. In it, provide your SNS topic ARN, bucket name, and bucket owner's account ID.

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "Example SNS topic policy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "SNS:Publish"  
            ],  
            "Resource": "SNS-topic-ARN",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::bucket-name"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "bucket-owner-account-id"  
                }  
            }  
        }  
    ]  
}
```

4. Note the topic ARN.

The SNS topic you created is another resource in your AWS account, and it has a unique ARN. You will need this ARN in the next step. The ARN will be of the following format:

```
arn:aws:sns:aws-region:account-id:topic-name
```

Step 3: Add a notification configuration to your bucket

You can enable bucket notifications either by using the Amazon S3 console or programmatically by using AWS SDKs. Choose any one of the options to configure notifications on your bucket. This section provides code examples using the AWS SDKs for Java and .NET.

Option A: Enable notifications on a bucket using the console

Using the Amazon S3 console, add a notification configuration requesting Amazon S3 to do the following:

- Publish events of the **All object create events** type to your Amazon SQS queue.
- Publish events of the **Object in RRS lost** type to your Amazon SNS topic.

After you save the notification configuration, Amazon S3 posts a test message, which you get via email.

For instructions, see [Enabling and configuring event notifications using the Amazon S3 console](#).

Option B: Enable notifications on a bucket using the AWS SDKs

.NET

The following C# code example provides a complete code listing that adds a notification configuration to a bucket. You must update the code and provide your bucket name and SNS topic ARN. For instructions on how to create and test a working sample, see [Running the Amazon S3 .NET Code Examples](#).

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
```

```
namespace Amazon.DocSamples.S3
{
    class EnableNotificationsTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string snsTopic = "*** SNS topic ARN ***";
        private const string sqsQueue = "*** SQS topic ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            EnableNotificationAsync().Wait();
        }

        static async Task EnableNotificationAsync()
        {
            try
            {
                PutBucketNotificationRequest request = new
PutBucketNotificationRequest
                {
                    BucketName = bucketName
                };

                TopicConfiguration c = new TopicConfiguration
                {
                    Events = new List<EventType> { EventType.ObjectCreatedCopy },
                    Topic = snsTopic
                };
                request.TopicConfigurations = new List<TopicConfiguration>();
                request.TopicConfigurations.Add(c);
                request.QueueConfigurations = new List<QueueConfiguration>();
                request.QueueConfigurations.Add(new QueueConfiguration()
                {
                    Events = new List<EventType> { EventType.ObjectCreatedPut },
                    Queue = sqsQueue
                });
            
```

```
        PutBucketNotificationResponse response = await
client.PutBucketNotificationAsync(request);
    }
    catch (AmazonS3Exception e)
    {
        Console.WriteLine("Error encountered on server. Message:'{0}' ",
e.Message);
    }
    catch (Exception e)
    {
        Console.WriteLine("Unknown error encountered on server.
Message:'{0}' ", e.Message);
    }
}
}
```

Java

The following example shows how to add a notification configuration to a bucket. For instructions on how to create and test a working sample, see [Testing the Amazon S3 Java Code Examples](#).

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.io.IOException;
import java.util.EnumSet;

public class EnableNotificationOnABucket {

    public static void main(String[] args) throws IOException {
        String bucketName = "*** Bucket name ***";
        Regions clientRegion = Regions.DEFAULT_REGION;
        String snsTopicARN = "*** SNS Topic ARN ***";
        String sqsQueueARN = "*** SQS Queue ARN ***";
    }
}
```

```
try {
    AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
        .withCredentials(new ProfileCredentialsProvider())
        .withRegion(clientRegion)
        .build();
    BucketNotificationConfiguration notificationConfiguration = new
BucketNotificationConfiguration();

    // Add an SNS topic notification.
    notificationConfiguration.addConfiguration("snsTopicConfig",
        new TopicConfiguration(snsTopicARN,
EnumSet.of(S3Event.ObjectCreated)));

    // Add an SQS queue notification.
    notificationConfiguration.addConfiguration("sqSQueueConfig",
        new QueueConfiguration(sqSQueueARN,
EnumSet.of(S3Event.ObjectCreated)));

    // Create the notification configuration request and set the bucket
notification
    // configuration.
    SetBucketNotificationConfigurationRequest request = new
SetBucketNotificationConfigurationRequest(
        bucketName, notificationConfiguration);
    s3Client.setBucketNotificationConfiguration(request);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Step 4: Test the setup

Now, you can test the setup by uploading an object to your bucket and verifying the event notification in the Amazon SQS console. For instructions, see [Receiving a Message](#) in the *Amazon Simple Queue Service Developer Guide "Getting Started"* section.

Configuring event notifications using object key name filtering

When configuring an Amazon S3 event notification, you must specify which supported Amazon S3 event types cause Amazon S3 to send the notification. If an event type that you didn't specify occurs in your S3 bucket, Amazon S3 doesn't send the notification.

You can configure notifications to be filtered by the prefix and suffix of the key name of objects. For example, you can set up a configuration where you're sent a notification only when image files with a ".jpg" file name extension are added to a bucket. Or, you can have a configuration that delivers a notification to an Amazon SNS topic when an object with the prefix "images/" is added to the bucket, while having notifications for objects with a "logs/" prefix in the same bucket delivered to an AWS Lambda function.

Note

A wildcard character ("*") can't be used in filters as a prefix or suffix. If your prefix or suffix contains a space, you must replace it with the "+" character. If you use any other special characters in the value of the prefix or suffix, you must enter them in [URL-encoded \(percent-encoded\) format](#). For a complete list of special characters that must be converted to URL-encoded format when used in a prefix or suffix for event notifications, see [Safe characters](#).

You can set up notification configurations that use object key name filtering in the Amazon S3 console. You can do so by using Amazon S3 APIs through the AWS SDKs or the REST APIs directly. For information about using the console UI to set a notification configuration on a bucket, see [Enabling and configuring event notifications using the Amazon S3 console](#).

Amazon S3 stores the notification configuration as XML in the *notification* subresource associated with a bucket as described in [Using Amazon SQS, Amazon SNS, and Lambda](#). You use the Filter XML structure to define the rules for notifications to be filtered by the prefix or suffix of an object key name. For information about the Filter XML structure, see [PUT Bucket notification](#) in the *Amazon Simple Storage Service API Reference*.

Notification configurations that use `Filter` cannot define filtering rules with overlapping prefixes, overlapping suffixes, or prefix and suffix overlapping. The following sections have examples of valid notification configurations with object key name filtering. They also contain examples of notification configurations that are not valid because of prefix and suffix overlapping.

Topics

- [Examples of valid notification configurations with object key name filtering](#)
- [Examples of notification configurations with invalid prefix and suffix overlapping](#)

Examples of valid notification configurations with object key name filtering

The following notification configuration contains a queue configuration identifying an Amazon SQS queue for Amazon S3 to publish events to of the `s3:ObjectCreated:Put` type. The events are published whenever an object that has a prefix of `images/` and a `.jpg` suffix is PUT to a bucket.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>images/</Value>
        </FilterRule>
        <FilterRule>
          <Name>suffix</Name>
          <Value>.jpg</Value>
        </FilterRule>
      </S3Key>
    </Filter>
    <Queue>arn:aws:sqs:us-west-2:44445556666:s3notificationqueue</Queue>
    <Event>s3:ObjectCreated:Put</Event>
  </QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping prefixes. The configuration defines that notifications for PUT requests in the `images/` folder go to queue-A, while notifications for PUT requests in the `logs/` folder go to queue-B.

```
<NotificationConfiguration>
```

```
<QueueConfiguration>
  <Id>1</Id>
  <Filter>
    <S3Key>
      <FilterRule>
        <Name>prefix</Name>
        <Value>images/</Value>
      </FilterRule>
    </S3Key>
  </Filter>
  <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-A</Queue>
  <Event>s3:ObjectCreated:Put</Event>
</QueueConfiguration>
<QueueConfiguration>
  <Id>2</Id>
  <Filter>
    <S3Key>
      <FilterRule>
        <Name>prefix</Name>
        <Value>logs/</Value>
      </FilterRule>
    </S3Key>
  </Filter>
  <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-B</Queue>
  <Event>s3:ObjectCreated:Put</Event>
</QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping suffixes. The configuration defines that all .jpg images newly added to the bucket are processed by Lambda cloud-function-A, and all newly added .png images are processed by cloud-function-B. The .png and .jpg suffixes aren't overlapping even though they have the same last letter. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can't end with both .png and .jpg, so the suffixes in the example configuration aren't overlapping suffixes.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>suffix</Name>
```

```
<Value>.jpg</Value>
</FilterRule>
</S3Key>
</Filter>
<CloudFunction>arn:aws:lambda:us-west-2:44445556666:cloud-function-A</
CloudFunction>
<Event>s3:ObjectCreated:Put</Event>
</CloudFunctionConfiguration>
<CloudFunctionConfiguration>
<Id>2</Id>
<Filter>
<S3Key>
<FilterRule>
<Name>suffix</Name>
<Value>.png</Value>
</FilterRule>
</S3Key>
</Filter>
<CloudFunction>arn:aws:lambda:us-west-2:44445556666:cloud-function-B</
CloudFunction>
<Event>s3:ObjectCreated:Put</Event>
</CloudFunctionConfiguration>
</NotificationConfiguration>
```

Your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes for the same event types. They can only do so, if the overlapping prefixes that are used with suffixes that don't overlap. The following example configuration shows how objects created with a common prefix but non-overlapping suffixes can be delivered to different destinations.

```
<NotificationConfiguration>
<CloudFunctionConfiguration>
<Id>1</Id>
<Filter>
<S3Key>
<FilterRule>
<Name>prefix</Name>
<Value>images</Value>
</FilterRule>
<FilterRule>
<Name>suffix</Name>
<Value>.jpg</Value>
</FilterRule>
</S3Key>
```

```
</Filter>
<CloudFunction>arn:aws:lambda:us-west-2:44445556666:cloud-function-A</
CloudFunction>
<Event>s3:ObjectCreated:Put</Event>
</CloudFunctionConfiguration>
<CloudFunctionConfiguration>
<Id>2</Id>
<Filter>
<S3Key>
<FilterRule>
<Name>prefix</Name>
<Value>images</Value>
</FilterRule>
<FilterRule>
<Name>suffix</Name>
<Value>.png</Value>
</FilterRule>
</S3Key>
</Filter>
<CloudFunction>arn:aws:lambda:us-west-2:44445556666:cloud-function-B</
CloudFunction>
<Event>s3:ObjectCreated:Put</Event>
</CloudFunctionConfiguration>
</NotificationConfiguration>
```

Examples of notification configurations with invalid prefix and suffix overlapping

For the most part, your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes, overlapping suffixes, or overlapping combinations of prefixes and suffixes for the same event types. You can have overlapping prefixes as long as the suffixes don't overlap. For an example, see [Configuring event notifications using object key name filtering](#).

You can use overlapping object key name filters with different event types. For example, you can create a notification configuration that uses the prefix `image/` for the `ObjectCreated:Put` event type and the prefix `image/` for the `ObjectRemoved:*` event type.

You get an error if you try to save a notification configuration that has invalid overlapping name filters for the same event types when using the Amazon S3 console or API. This section shows examples of notification configurations that aren't valid because of overlapping name filters.

Any existing notification configuration rule is assumed to have a default prefix and suffix that match any other prefix and suffix, respectively. The following notification configuration isn't valid

because it has overlapping prefixes. Specifically, the root prefix overlaps with any other prefix. The same thing is true if you use a suffix instead of a prefix in this example. The root suffix overlaps with any other suffix.

```
<NotificationConfiguration>
  <TopicConfiguration>
    <Topic>arn:aws:sns:us-west-2:44445556666:sns-notification-one</Topic>
    <Event>s3:ObjectCreated:*</Event>
  </TopicConfiguration>
  <TopicConfiguration>
    <Topic>arn:aws:sns:us-west-2:44445556666:sns-notification-two</Topic>
    <Event>s3:ObjectCreated:*</Event>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>images</Value>
        </FilterRule>
      </S3Key>
    </Filter>
  </TopicConfiguration>
</NotificationConfiguration>
```

The following notification configuration isn't valid because it has overlapping suffixes. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can end with jpg and pg. So, the suffixes overlap. The same is true for prefixes. If a given string can begin with both prefixes, the two prefixes are considered overlapping.

```
<NotificationConfiguration>
  <TopicConfiguration>
    <Topic>arn:aws:sns:us-west-2:44445556666:sns-topic-one</Topic>
    <Event>s3:ObjectCreated:*</Event>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>suffix</Name>
          <Value>jpg</Value>
        </FilterRule>
      </S3Key>
    </Filter>
  </TopicConfiguration>
  <TopicConfiguration>
```

```
<Topic>arn:aws:sns:us-west-2:444455556666:sns-topic-two</Topic>
<Event>s3:ObjectCreated:Put</Event>
<Filter>
  <S3Key>
    <FilterRule>
      <Name>suffix</Name>
      <Value>pg</Value>
    </FilterRule>
  </S3Key>
</Filter>
</TopicConfiguration>
</NotificationConfiguration>
```

The following notification configuration isn't valid because it has overlapping prefixes and suffixes.

```
<NotificationConfiguration>
  <TopicConfiguration>
    <Topic>arn:aws:sns:us-west-2:444455556666:sns-topic-one</Topic>
    <Event>s3:ObjectCreated:*</Event>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>images</Value>
        </FilterRule>
        <FilterRule>
          <Name>suffix</Name>
          <Value>jpg</Value>
        </FilterRule>
      </S3Key>
    </Filter>
  </TopicConfiguration>
  <TopicConfiguration>
    <Topic>arn:aws:sns:us-west-2:444455556666:sns-topic-two</Topic>
    <Event>s3:ObjectCreated:Put</Event>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>suffix</Name>
          <Value>jpg</Value>
        </FilterRule>
      </S3Key>
    </Filter>
  </TopicConfiguration>
</NotificationConfiguration>
```

```
</TopicConfiguration>
</NotificationConfiguration>
```

Event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format.

For a general overview and instructions on configuring event notifications, see [Amazon S3 Event Notifications](#).

This example shows *version 2.2* of the event notification JSON structure. Amazon S3 uses *versions 2.1, 2.2, and 2.3* of this event structure. Amazon S3 uses version 2.2 for cross-Region replication event notifications. It uses version 2.3 for S3 Lifecycle, S3 Intelligent-Tiering, object ACL, object tagging, and object restoration delete events. These versions contain extra information specific to these operations. Versions 2.2 and 2.3 are otherwise compatible with version 2.1, which Amazon S3 currently uses for all other event notification types.

```
{
    "Records": [
        {
            "eventVersion": "2.2",
            "eventSource": "aws:s3",
            "awsRegion": "us-west-2",
            "eventTime": "The time, in ISO-8601 format, for example,  
1970-01-01T00:00:00.000Z, when Amazon S3 finished processing the request",
            "eventName": "event-type",
            "userIdentity": {
                "principalId": "Amazon-customer-ID-of-the-user-who-caused-the-event"
            },
            "requestParameters": {
                "sourceIPAddress": "ip-address-where-request-came-from"
            },
            "responseElements": {
                "x-amz-request-id": "Amazon S3 generated request ID",
                "x-amz-id-2": "Amazon S3 host that processed the request"
            },
            "s3": {
                "s3SchemaVersion": "1.0",
                "configurationId": "ID found in the bucket notification configuration",

    "key": "object-key",
    "size": "object-size in bytes",
    "eTag": "object eTag",
    "versionId": "object version if bucket is versioning-enabled, otherwise null",
    "sequencer": "a string representation of a hexadecimal value used to determine event sequence, only used with PUTs and DELETEs"
}
},
"glacierEventData": {
    "restoreEventData": {
        "lifecycleRestorationExpiryTime": "The time, in ISO-8601 format, for example, 1970-01-01T00:00:00.000Z, of Restore Expiry",
        "lifecycleRestoreStorageClass": "Source storage class for restore"
    }
}
]
}
```

Note the following about the event message structure:

- The eventVersion key value contains a major and minor version in the form <major>.<minor>.

The major version is incremented if Amazon S3 makes a change to the event structure that's not backward compatible. This includes removing a JSON field that's already present or changing how the contents of a field are represented (for example, a date format).

The minor version is incremented if Amazon S3 adds new fields to the event structure. This might occur if new information is provided for some or all existing events. This might also occur if new information is provided on only newly introduced event types. Applications should ignore new fields to stay forward compatible with new minor versions of the event structure.

If new event types are introduced but the structure of the event is otherwise unmodified, the event version doesn't change.

To ensure that your applications can parse the event structure correctly, we recommend that you do an equal-to comparison on the major version number. To ensure that the fields that are expected by your application are present, we also recommend doing a greater-than-or-equal-to comparison on the minor version.

- The `eventName` references the list of [event notification types](#) but doesn't contain the `s3:` prefix.
- The `responseElements` key value is useful if you want to trace a request by following up with AWS Support. Both `x-amz-request-id` and `x-amz-id-2` help Amazon S3 trace an individual request. These values are the same as those that Amazon S3 returns in the response to the request that initiates the events. This is so they can be used to match the event to the request.
- The `s3` key provides information about the bucket and object involved in the event. The object key name value is URL encoded. For example, "red flower.jpg" becomes "red+flower.jpg" (Amazon S3 returns "application/x-www-form-urlencoded" as the content type in the response).
- The `sequencer` key provides a way to determine the sequence of events. Event notifications aren't guaranteed to arrive in the same order that the events occurred. However, notifications from events that create objects (PUTs) and delete objects contain a `sequencer`. It can be used to determine the order of events for a given object key.

If you compare the `sequencer` strings from two event notifications on the same object key, the event notification with the greater `sequencer` hexadecimal value is the event that occurred later. If you're using event notifications to maintain a separate database or index of your Amazon S3 objects, we recommend that you compare and store the `sequencer` values as you process each event notification.

Note the following:

- You can't use `sequencer` to determine order for events on different object keys.
- The `sequencers` can be of different lengths. So, to compare these values, first right pad the shorter value with zeros, and then do a lexicographical comparison.
- The `glacierEventData` key is only visible for `s3:ObjectRestore:Completed` events.
- The `restoreEventData` key contains attributes that are related to your restore request.
- The `replicationEventData` key is only visible for replication events.
- The `intelligentTieringEventData` key is only visible for S3 Intelligent-Tiering events.
- The `lifecycleEventData` key is only visible for S3 Lifecycle transition events.

Example messages

The following are examples of Amazon S3 event notification messages.

Amazon S3 test message

After you configure an event notification on a bucket, Amazon S3 sends the following test message.

```
{  
    "Service": "Amazon S3",  
    "Event": "s3:TestEvent",  
    "Time": "2014-10-13T15:57:02.089Z",  
    "Bucket": "bucketname",  
    "RequestId": "5582815E1AEA5ADF",  
    "HostId": "8cLeGAmw098X5cv4Zkwcmo8vvZa3eH3eKxsPzbB9wrR+YstdA6Knx4Ip8EXAMPLE"  
}
```

Example message when an object is created using a PUT request

The following message is an example of a message Amazon S3 sends to publish an s3:ObjectCreated:Put event.

```
{  
    "Records": [  
        {  
            "eventVersion": "2.1",  
            "eventSource": "aws:s3",  
            "awsRegion": "us-west-2",  
            "eventTime": "1970-01-01T00:00:00.000Z",  
            "eventName": "ObjectCreated:Put",  
            "userIdentity": {  
                "principalId": "AIDAJDPLRKLG7UEXAMPLE"  
            },  
            "requestParameters": {  
                "sourceIPAddress": "127.0.0.1"  
            },  
            "responseElements": {  
                "x-amz-request-id": "C3D13FE58DE4C810",  
                "x-amz-id-2": "FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/  
JRWeUWerMUE5JgHvANOjpD"  
            },  
            "s3": {  
                "objectKey": "testfile.txt",  
                "objectSize": 1024,  
                "bucket": "mybucket",  
                "versionId": "20140820T123456Z",

For a definition of each IAM identification prefix (for example, AIDA, AROA, AGPA), see [IAM identifiers](#) in the *IAM User Guide*.

Using EventBridge

Amazon S3 can send events to Amazon EventBridge whenever certain events happen in your bucket. Unlike other destinations, you don't need to select which event types you want to deliver. After EventBridge is enabled, all events below are sent to EventBridge. You can use EventBridge rules to route events to additional targets. The following lists the events Amazon S3 sends to EventBridge.

Event type	Description
<i>Object Created</i>	An object was created. The reason field in the event message structure indicates which S3 API was used to create the object: PutObject , POST Object , CopyObject , or CompleteMultipartUpload .
<i>Object Deleted (DeleteObject)</i>	An object was deleted.

Event type	Description
<i>Object Deleted (Lifecycle expiration)</i>	<p>When an object is deleted using an S3 API call, the reason field is set to DeleteObject. When an object is deleted by an S3 Lifecycle expiration rule, the reason field is set to Lifecycle Expiration. For more information, see Expiring objects.</p> <p>When an unversioned object is deleted, or a versioned object is permanently deleted, the deletion-type field is set to Permanently Deleted. When a delete marker is created for a versioned object, the deletion-type field is set to Delete Marker Created. For more information, see Deleting object versions from a versioning-enabled bucket.</p>
<i>Object Restore Initiated</i>	An object restore was initiated from S3 Glacier or S3 Glacier Deep Archive storage class or from S3 Intelligent-Tiering Archive Access or Deep Archive Access tier. For more information, see Working with archived objects .
<i>Object Restore Completed</i>	An object restore was completed.
<i>Object Restore Expired</i>	The temporary copy of an object restored from S3 Glacier or S3 Glacier Deep Archive expired and was deleted.
<i>Object Storage Class Changed</i>	An object was transitioned to a different storage class. For more information, see Transitioning objects using Amazon S3 Lifecycle .
<i>Object Access Tier Changed</i>	An object was transitioned to the S3 Intelligent-Tiering Archive Access tier or Deep Archive Access tier. For more information, see Amazon S3 Intelligent-Tiering .
<i>Object ACL Updated</i>	An object's access control list (ACL) was set using PutObjectACL. An event is not generated when a request results in no change to an object's ACL. For more information, see Access control list (ACL) overview .

Event type	Description
<i>Object Tags Added</i>	A set of tags was added to an object using PutObject Tagging. For more information, see Categorizing your storage using tags .
<i>Object Tags Deleted</i>	All tags were removed from an object using DeleteObjectTagging. For more information, see Categorizing your storage using tags .

 **Note**

For more information about how Amazon S3 event types map to EventBridge event types, see [Amazon EventBridge mapping and troubleshooting](#).

You can use Amazon S3 Event Notifications with EventBridge to write rules that take actions when an event occurs in your bucket. For example, you can have it send you a notification. For more information, see [What is EventBridge](#) in the *Amazon EventBridge User Guide*.

For information about pricing, see [Amazon EventBridge pricing](#).

Topics

- [Amazon EventBridge permissions](#)
- [Enabling Amazon EventBridge](#)
- [EventBridge event message structure](#)
- [Amazon EventBridge mapping and troubleshooting](#)

Amazon EventBridge permissions

Amazon S3 does not require any additional permissions to deliver events to Amazon EventBridge.

Enabling Amazon EventBridge

You can enable Amazon EventBridge using the S3 console, AWS Command Line Interface (AWS CLI), or Amazon S3 REST API.

Using the S3 console

To enable EventBridge event delivery in the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to enable events for.
3. Choose **Properties**.
4. Navigate to the **Event Notifications** section and find the **Amazon EventBridge** subsection. Choose **Edit**.
5. Under **Send notifications to Amazon EventBridge for all events in this bucket** choose **On**.

 **Note**

After you enable EventBridge, it takes around five minutes for the changes to take effect.

Using the AWS CLI

The following example creates a bucket notification configuration for bucket **DOC-EXAMPLE-BUCKET1** with Amazon EventBridge enabled.

```
aws s3api put-bucket-notification-configuration --bucket DOC-EXAMPLE-BUCKET1 --  
notification-configuration='{"EventBridgeConfiguration": {} }'
```

Using the REST API

You can programmatically enable Amazon EventBridge on a bucket by calling the Amazon S3 REST API. For more information see, see [PutBucketNotificationConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

The following example shows the XML used to create a bucket notification configuration with Amazon EventBridge enabled.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">  
  <EventBridgeConfiguration>  
  </EventBridgeConfiguration>  
</NotificationConfiguration>
```

Creating EventBridge rules

Once enabled you can create Amazon EventBridge rules for certain tasks. For example, you can send email notifications when an object is created. For a full tutorial, see [Tutorial: Send a notification when an Amazon S3 object is created](#) in the *Amazon EventBridge User Guide*.

EventBridge event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format. When Amazon S3 sends an event to Amazon EventBridge, the following fields are present.

- **version** — Currently 0 (zero) for all events.
- **id** — A Version 4 UUID generated for every event.
- **detail-type** — The type of event that's being sent. See [Using EventBridge](#) for a list of event types.
- **source** — Identifies the service that generated the event.
- **account** — The 12-digit AWS account ID of the bucket owner.
- **time** — The time the event occurred.
- **region** — Identifies the AWS Region of the bucket.
- **resources** — A JSON array that contains the Amazon Resource Name (ARN) of the bucket.
- **detail** — A JSON object that contains information about the event. For more information about what can be included in this field, see [Event message detail field](#).

Event message structure examples

The following are examples of some of the Amazon S3 event notification messages that can be sent to Amazon EventBridge.

Object created

        },  
        "object": {  
            "key": "example-key",  
            "size": 5,  
            "etag": "b1946ac92492d2347c6235b4d2611184",  
            "version-id": "KKsjUC1.6gIjqtvhfg5AdMI0eCePIiT3"  
        },  
        "request-id": "189F19CB7FB1B6A4",  
        "requester": "s3.amazonaws.com",  
        "restore-expiry-time": "2021-11-13T00:00:00Z",  
        "source-storage-class": "GLACIER"  
    }  
}
```

Event message detail field

The detail field contains a JSON object with information about the event. The following fields may be present in the detail field.

- **version** — Currently 0 (zero) for all events.
- **bucket** — Information about the Amazon S3 bucket involved in the event.
- **object** — Information about the Amazon S3 object involved in the event.

- **request-id** — Request ID in S3 response.
- **requester** — AWS account ID or AWS service principal of requester.
- **source-ip-address** — Source IP address of S3 request. Only present for events triggered by an S3 request.
- **reason** — For **Object Created** events, the S3 API used to create the object: [PutObject](#), [POST Object](#), [CopyObject](#), or [CompleteMultipartUpload](#). For **Object Deleted** events, this is set to **DeleteObject** when an object is deleted by an S3 API call, or **Lifecycle Expiration** when an object is deleted by an S3 Lifecycle expiration rule. For more information, see [Expiring objects](#).
- **deletion-type** — For **Object Deleted** events, when an unversioned object is deleted, or a versioned object is permanently deleted, this is set to **Permanently Deleted**. When a delete marker is created for a versioned object, this is set to **Delete Marker Created**. For more information, see [Deleting object versions from a versioning-enabled bucket](#).
- **restore-expiry-time** — For **Object Restore Completed** events, the time when the temporary copy of the object will be deleted from S3. For more information, see [Working with archived objects](#).
- **source-storage-class** — For **Object Restore Initiated** and **Object Restore Completed** events, the storage class of the object being restored. For more information, see [Working with archived objects](#).
- **destination-storage-class** — For **Object Storage Class Changed** events, the new storage class of the object. For more information, see [Transitioning objects using Amazon S3 Lifecycle](#).
- **destination-access-tier** — For **Object Access Tier Changed** events, the new access tier of the object. For more information, see [Amazon S3 Intelligent-Tiering](#).

Amazon EventBridge mapping and troubleshooting

The following table describes how Amazon S3 event types are mapped to Amazon EventBridge event types.

S3 event type	Amazon EventBridge detail type
ObjectCreated:Put	Object Created
ObjectCreated:Post	
ObjectCreated:Copy	

S3 event type	Amazon EventBridge detail type
ObjectCreated:CompleteMultiPartUpload	
ObjectRemoved:Delete	Object Deleted
ObjectRemoved:DeleteMarkerCreated	
LifecycleExpiration:Delete	
LifecycleExpiration:DeleteMarkerCreated	
ObjectRestore:Post	Object Restore Initiated
ObjectRestore:Completed	Object Restore Completed
ObjectRestore:Delete	Object Restore Expired
LifecycleTransition	Object Storage Class Changed
IntelligentTiering	Object Access Tier Changed
ObjectTagging:Put	Object Tags Added
ObjectTagging:Delete	Object Tags Deleted
ObjectAcl:Put	Object ACL Updated

Amazon EventBridge troubleshooting

For information about how to troubleshoot EventBridge, see [Troubleshooting Amazon EventBridge](#) in the *Amazon EventBridge User Guide*.

Using analytics and insights

You can use analytics and insights in Amazon S3 to understand, analyze, and optimize your storage usage . For more information, see the topics below.

Topics

- [Amazon S3 analytics – Storage Class Analysis](#)
- [Assessing your storage activity and usage with Amazon S3 Storage Lens](#)
- [Tracing Amazon S3 requests using AWS X-Ray](#)

Amazon S3 analytics – Storage Class Analysis

By using Amazon S3 analytics *Storage Class Analysis* you can analyze storage access patterns to help you decide when to transition the right data to the right storage class. This new Amazon S3 analytics feature observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. For more information about storage classes, see [Using Amazon S3 storage classes](#).

After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. You can configure storage class analysis to analyze all the objects in a bucket. Or, you can configure filters to group objects together for analysis by common prefix (that is, objects that have names that begin with a common string), by object tags, or by both prefix and tags. You'll most likely find that filtering by object groups is the best way to benefit from storage class analysis.

Important

Storage class analysis only provides recommendations for Standard to Standard IA classes.

You can have multiple storage class analysis filters per bucket, up to 1,000, and will receive a separate analysis for each filter. Multiple filter configurations allow you analyze specific groups of objects to improve your lifecycle configurations that transition objects to STANDARD_IA.

Storage class analysis provides storage usage visualizations in the Amazon S3 console that are updated daily. You can also export this daily usage data to an S3 bucket and view them in a spreadsheet application, or with business intelligence tools, like Amazon QuickSight.

There are costs associated with the storage class analysis. For pricing information, see *Management and replication* [Amazon S3 pricing](#).

Topics

- [How do I set up storage class analysis?](#)
- [How do I use storage class analysis?](#)
- [How can I export storage class analysis data?](#)
- [Configuring storage class analysis](#)

How do I set up storage class analysis?

You set up storage class analysis by configuring what object data you want to analyze. You can configure storage class analysis to do the following:

- **Analyze the entire contents of a bucket.**

You'll receive an analysis for all the objects in the bucket.

- **Analyze objects grouped together by prefix and tags.**

You can configure filters that group objects together for analysis by prefix, or by object tags, or by a combination of prefix and tags. You receive a separate analysis for each filter you configure. You can have multiple filter configurations per bucket, up to 1,000.

- **Export analysis data.**

When you configure storage class analysis for a bucket or filter, you can choose to have the analysis data exported to a file each day. The analysis for the day is added to the file to form a historic analysis log for the configured filter. The file is updated daily at the destination of your choice. When selecting data to export, you specify a destination bucket and optional destination prefix where the file is written.

You can use the Amazon S3 console, the REST API, or the AWS CLI or AWS SDKs to configure storage class analysis.

- For information about how to configure storage class analysis in the Amazon S3 console, see [Configuring storage class analysis](#).
- To use the Amazon S3 API, use the [PutBucketAnalyticsConfiguration](#) REST API, or the equivalent, from the AWS CLI or AWS SDKs.

How do I use storage class analysis?

You use storage class analysis to observe your data access patterns over time to gather information to help you improve the lifecycle management of your STANDARD_IA storage. After you configure a filter, you'll start seeing data analysis based on the filter in the Amazon S3 console in 24 to 48 hours. However, storage class analysis observes the access patterns of a filtered data set for 30 days or longer to gather information for analysis before giving a result. The analysis continues to run after the initial result and updates the result as the access patterns change.

When you first configure a filter, the Amazon S3 console may take a moment to analyze your data.

Storage class analysis observes the access patterns of a filtered object data set for 30 days or longer to gather enough information for the analysis. After storage class analysis has gathered sufficient information, you'll see a message in the Amazon S3 console that analysis is complete.

When performing the analysis for infrequently accessed objects storage class analysis looks at the filtered set of objects grouped together based on age since they were uploaded to Amazon S3. Storage class analysis determines if the age group is infrequently accessed by looking at the following factors for the filtered data set:

- Objects in the STANDARD storage class that are larger than 128 KB.
- How much average total storage you have per age group.
- Average number of bytes transferred out (not frequency) per age group.
- Analytics export data only includes requests with data relevant to storage class analysis. This might cause differences in the number of requests, and the total upload and request bytes compared to what are shown in storage metrics or tracked by your own internal systems.
- Failed GET and PUT requests are not counted for the analysis. However, you will see failed requests in storage metrics.

How Much of My Storage did I Retrieve?

The Amazon S3 console graphs how much of the storage in the filtered data set has been retrieved for the observation period.

What Percentage of My Storage did I Retrieve?

The Amazon S3 console also graphs what percentage of the storage in the filtered data set has been retrieved for the observation period.

As stated earlier in this topic, when you are performing the analysis for infrequently accessed objects, storage class analysis looks at the filtered set of objects grouped together based on the age since they were uploaded to Amazon S3. The storage class analysis uses the following predefined object age groups:

- Amazon S3 Objects less than 15 days old
- Amazon S3 Objects 15-29 days old
- Amazon S3 Objects 30-44 days old
- Amazon S3 Objects 45-59 days old
- Amazon S3 Objects 60-74 days old
- Amazon S3 Objects 75-89 days old
- Amazon S3 Objects 90-119 days old
- Amazon S3 Objects 120-149 days old
- Amazon S3 Objects 150-179 days old
- Amazon S3 Objects 180-364 days old
- Amazon S3 Objects 365-729 days old
- Amazon S3 Objects 730 days and older

Usually it takes about 30 days of observing access patterns to gather enough information for an analysis result. It might take longer than 30 days, depending on the unique access pattern of your data. However, after you configure a filter you'll start seeing data analysis based on the filter in the Amazon S3 console in 24 to 48 hours. You can see analysis on a daily basis of object access broken down by object age group in the Amazon S3 console.

How Much of My Storage is Infrequently Accessed?

The Amazon S3 console shows the access patterns grouped by the predefined object age groups. The **Frequently accessed** or **Infrequently accessed** text shown is meant as a visual aid to help you in the lifecycle creation process.

How can I export storage class analysis data?

You can choose to have storage class analysis export analysis reports to a comma-separated values (CSV) flat file. Reports are updated daily and are based on the object age group filters you configure. When using the Amazon S3 console you can choose the export report option when you create a filter. When selecting data export you specify a destination bucket and optional

destination prefix where the file is written. You can export the data to a destination bucket in a different account. The destination bucket must be in the same region as the bucket that you configure to be analyzed.

You must create a bucket policy on the destination bucket to grant permissions to Amazon S3 to verify what AWS account owns the bucket and to write objects to the bucket in the defined location. For an example policy, see [Grant permissions for S3 Inventory and S3 analytics](#).

After you configure storage class analysis reports, you start getting the exported report daily after 24 hours. After that, Amazon S3 continues monitoring and providing daily exports.

You can open the CSV file in a spreadsheet application or import the file into other applications like [Amazon QuickSight](#). For information on using Amazon S3 files with Amazon QuickSight, see [Create a Data Set Using Amazon S3 Files](#) in the *Amazon QuickSight User Guide*.

Data in the exported file is sorted by date within object age group as shown in following examples. If the storage class is STANDARD the row also contains data for the columns `ObjectAgeForSIATransition` and `RecommendedObjectAgeForSIATransition`.

Date	ConfigId	Filter	StorageClass	ObjectAge	ObjectCount	DataUploaded_MB	Storage_MB	DataRetrieved_MB	GetRequestCount	CumulativeAccessRatio	ObjectAgeForSIATransition	RecommendedObjectAgeForSIATransition
8/17/2021	SalesMaterial	SalesMaterial	STANDARD	000-014		0.4313				0		
9/2/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/22/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
8/25/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/6/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/30/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/28/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/21/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/5/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		

At the end of the report the object age group is given as ALL. The ALL rows contain cumulative totals, including objects smaller than 128 KB, for all the age groups for that day.

8/24/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
9/3/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.02426125 015-029		
8/28/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.03545875 015-029		
8/17/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/25/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
9/6/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.0209529 015-029		
9/4/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.02304819 015-029		
8/22/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/21/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/30/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.03073092 015-029		
8/20/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		

The next section describes the columns used in the report.

Exported file layout

The following table describe the layout of the exported file.

Configuring storage class analysis

By using the Amazon S3 analytics storage class analysis tool, you can analyze storage access patterns to help you decide when to transition the right data to the right storage class. Storage

class analysis observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. For more information about STANDARD_IA, see the [Amazon S3 FAQ](#) and [Using Amazon S3 storage classes](#).

You set up storage class analysis by configuring what object data you want to analyze. You can configure storage class analysis to do the following:

- **Analyze the entire contents of a bucket.**

You'll receive an analysis for all the objects in the bucket.

- **Analyze objects grouped together by prefix and tags.**

You can configure filters that group objects together for analysis by prefix, or by object tags, or by a combination of prefix and tags. You receive a separate analysis for each filter you configure. You can have multiple filter configurations per bucket, up to 1,000.

- **Export analysis data.**

When you configure storage class analysis for a bucket or filter, you can choose to have the analysis data exported to a file each day. The analysis for the day is added to the file to form a historic analysis log for the configured filter. The file is updated daily at the destination of your choice. When selecting data to export, you specify a destination bucket and optional destination prefix where the file is written.

You can use the Amazon S3 console, the REST API, or the AWS CLI or AWS SDKs to configure storage class analysis.

Important

Storage class analysis does not give recommendations for transitions to the ONEZONE_IA or S3 Glacier Flexible Retrieval storage classes.

If you want to configure storage class analysis to export your findings as a .csv file and the destination bucket uses default bucket encryption with a AWS KMS key, you must update the AWS KMS key policy to grant Amazon S3 permission to encrypt the .csv file. For instructions, see [Granting Amazon S3 permission to use your customer managed key for encryption](#).

For more information about analytics, see [Amazon S3 analytics – Storage Class Analysis](#).

Using the S3 console

To configure storage class analysis

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket for which you want to configure storage class analysis.
3. Choose the **Metrics** tab.
4. Under **Storage Class Analysis**, choose **Create analytics configuration**.
5. Type a name for the filter. If you want to analyze the whole bucket, leave the **Prefix** field empty.
6. In the **Prefix** field, type text for the prefix for the objects that you want to analyze.
7. To add a tag, choose **Add tag**. Enter a key and value for the tag. You can enter one prefix and multiple tags.
8. Optionally, you can choose **Enable** under **Export CSV** to export analysis reports to a comma-separated values (.csv) flat file. Choose a destination bucket where the file can be stored. You can type a prefix for the destination bucket. The destination bucket must be in the same AWS Region as the bucket for which you are setting up the analysis. The destination bucket can be in a different AWS account.

If the destination bucket for the .csv file uses default bucket encryption with a KMS key, you must update the AWS KMS key policy to grant Amazon S3 permission to encrypt the .csv file. For instructions, see [Granting Amazon S3 permission to use your customer managed key for encryption](#).

9. Choose **Create Configuration**.

Amazon S3 creates a bucket policy on the destination bucket that grants Amazon S3 write permission. This allows it to write the export data to the bucket.

If an error occurs when you try to create the bucket policy, you'll be given instructions on how to fix it. For example, if you chose a destination bucket in another AWS account and do not have permissions to read and write to the bucket policy, you'll see the following message. You must have the destination bucket owner add the displayed bucket policy to the destination bucket. If

the policy is not added to the destination bucket you won't get the export data because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, then the correct account ID of the source bucket must be substituted in the policy.

For information about the exported data and how the filter works, see [Amazon S3 analytics – Storage Class Analysis](#).

Using the REST API

To configure Storage Class Analysis using the REST API, use the [PutBucketAnalyticsConfiguration](#). You can also use the equivalent operation with the AWS CLI or AWS SDKs.

You can use the following REST APIs to work with Storage Class Analysis:

- [DELETE Bucket Analytics configuration](#)
- [GET Bucket Analytics configuration](#)
- [List Bucket Analytics Configuration](#)

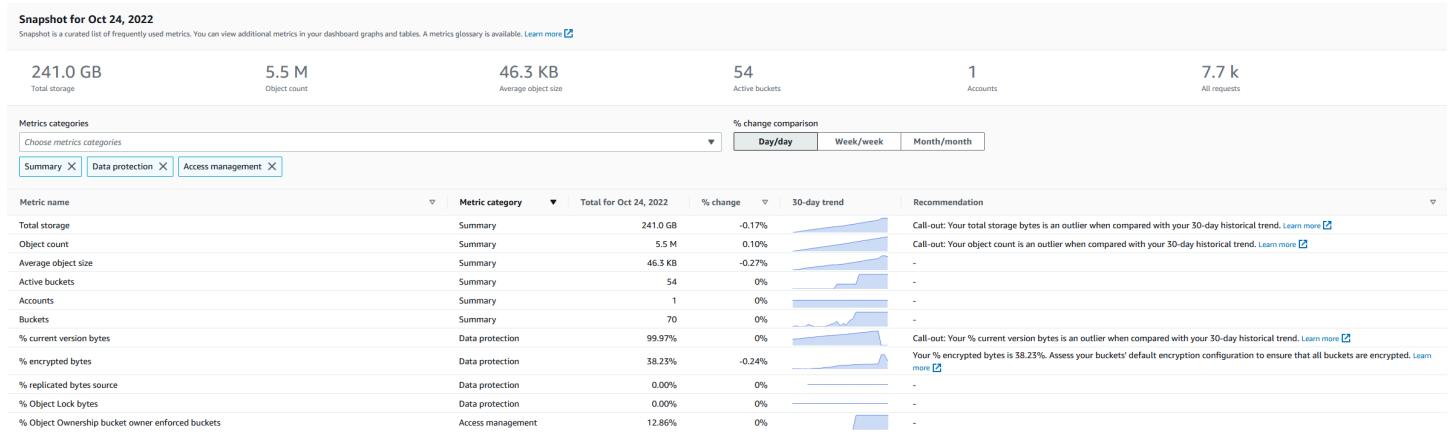

Assessing your storage activity and usage with Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object storage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

You can use S3 Storage Lens metrics to generate summary insights. For example, you can find out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and access-management best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to abort incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an

interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

S3 Storage Lens metrics and features

S3 Storage Lens provides an interactive *default dashboard* that is updated daily. S3 Storage Lens preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. Metrics from this dashboard are also summarized in your account snapshot on the **Buckets** page. For more information, see [Default dashboard](#).

To create other dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations), you create an S3 Storage Lens dashboard configuration. You can create and manage S3 Storage Lens dashboard configurations by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

S3 Storage Lens offers free metrics and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. These features include advanced metric categories, prefix aggregation, contextual recommendations, and Amazon CloudWatch publishing. Prefix aggregation and contextual recommendations are available only in the Amazon S3 console. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

Metrics categories

Within the free and advanced tiers, metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to advanced metrics and recommendations, you can enable advanced cost-optimization and data-protection metrics. You can use these advanced metrics to further reduce your S3 storage costs and improve your data-protection stance. You can also enable activity metrics and detailed status-code metrics to improve the performance of application workloads that are accessing your S3 buckets. For more information about the free and advanced metrics categories, see [Metrics selection](#).

You can assess your storage based on S3 best practices, such as analyzing the percentage of your buckets that have encryption or S3 Object Lock or S3 Versioning enabled. You can also identify potential cost-savings opportunities. For example, you can use S3 Lifecycle rule count metrics to identify buckets that are missing lifecycle expiration or transition rules. You can also analyze your request activity per bucket to find buckets where objects could be transitioned to a lower-cost storage class. For more information, see [Amazon S3 Storage Lens metrics use cases](#).

Metrics export

In addition to viewing the dashboard on the S3 console, you can export metrics in CSV or Parquet format to an S3 bucket for further analysis with the analytics tool of your choice. For more information, see [Viewing Amazon S3 Storage Lens metrics using a data export](#).

Amazon CloudWatch publishing

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For more information about support for S3 Storage Lens metrics in CloudWatch, see [Monitor S3 Storage Lens metrics in CloudWatch](#).

For more information about using S3 Storage Lens, see the following topics.

Topics

- [Understanding Amazon S3 Storage Lens](#)
- [Using Amazon S3 Storage Lens with AWS Organizations](#)

- [Amazon S3 Storage Lens permissions](#)
- [Viewing metrics with Amazon S3 Storage Lens](#)

- [Working with S3 Storage Lens groups](#)

Understanding Amazon S3 Storage Lens

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive

recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket. You can create and manage S3 Storage Lens dashboards by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

S3 Storage Lens concepts and terminology

This section contains the terminology and concepts that are essential for successfully understanding and using Amazon S3 Storage Lens.

Topics

- [Dashboard configuration](#)
- [Default dashboard](#)
- [Dashboards](#)
- [Account snapshot](#)
- [Metrics export](#)
- [Home Region](#)
- [Retention period](#)
- [Metrics categories](#)
- [Recommendations](#)
- [Metrics selection](#)
- [S3 Storage Lens and AWS Organizations](#)

Dashboard configuration

S3 Storage Lens requires a dashboard configuration that contains the properties required to aggregate metrics on your behalf for a single dashboard or export. When you create a configuration, you choose the dashboard name and the home Region, which you can't change after you create the dashboard. You can optionally add tags and configure a metrics export in CSV or Parquet format.

In the dashboard configuration, you also define the dashboard scope and the metrics selection. The scope can include all the storage for your organization account or sections that are filtered by Region, bucket, and account. When you configure the metrics selection, you choose between free

metrics and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

Default dashboard

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. S3 preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from free metrics to advanced metrics and recommendations. You can configure the optional metrics export or even disable the dashboard. However, you can't delete the default dashboard.

Note

If you disable your default dashboard, it is no longer updated. You'll no longer receive any new daily metrics in your S3 Storage Lens dashboard, your metrics export, or the account snapshot on the **S3 Buckets** page. If your dashboard uses advanced metrics and recommendations, you'll no longer be charged. You can still see historic data in the dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics and recommendations. To access historic data, you can re-enable the dashboard within the expiration period.

Dashboards

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations). When you create or edit a S3 Storage Lens dashboard, you define your dashboard scope and metrics selection. S3 Storage Lens offers free metrics and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. These include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

You can also disable or delete dashboards. If you disable a dashboard, it is no longer updated, and you will no longer receive any new daily metrics. You can still see historic data until the 14-day

expiration period. If you enabled advanced metrics and recommendations for that dashboard, this period is 15 months. To access historic data, you can re-enable the dashboard within the expiration period.

If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

Note

- You can use S3 Storage Lens to create up to 50 dashboards per home Region.
- Organization-level dashboards can be limited only to a Regional scope.

Account snapshot

The S3 Storage Lens **Account snapshot** summarizes metrics from your default dashboard and displays your total storage, object count, and average object size on the S3 console **Buckets** page. This account snapshot gives you quick access to insights about your storage without having to leave the **Buckets** page. The account snapshot also provides one-click access to your interactive S3 Storage Lens dashboard.

You can use your dashboard to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate insights at the organization, account, bucket, object, or prefix level. You can also send a once-daily metrics export to an S3 bucket in CSV or Parquet format.

You can't modify the dashboard scope of the **default-account dashboard** because it's linked to the **Account snapshot**. However, you can upgrade the metrics selection in your **default-account-dashboard** from free metrics to paid advanced metrics and recommendations. After upgrading, you can then display all requests, bytes uploaded, and bytes downloaded in the S3 Storage Lens **Account snapshot**.

Note

If you disable your default dashboard, your **Account snapshot** is no longer updated. To continue displaying metrics in the **Account snapshot**, you can re-enable the **default-account-dashboard**.

Metrics export

An S3 Storage Lens metrics export is a file that contains all the metrics identified in your S3 Storage Lens configuration. This information is generated daily in CSV or Parquet format and is sent to an S3 bucket. You can use the metrics export for further analysis by using the metrics tool of your choice. The S3 bucket for your metrics export must be in the same Region as your S3 Storage Lens configuration. You can generate an S3 Storage Lens metrics export from the S3 console by editing your dashboard configuration. You can also configure a metrics export by using the AWS CLI and AWS SDKs.

Home Region

The home Region is the AWS Region where all S3 Storage Lens metrics for a given dashboard configuration are stored. You must choose a home Region when you create your S3 Storage Lens dashboard configuration. After you choose a home Region, you can't change it. Also, if you're creating a Storage Lens group, we recommend that you choose the same home Region as your Storage Lens dashboard.

Note

You can choose one of the following Regions as your home Region:

- US East (N. Virginia) – us-east-1
- US East (Ohio) – us-east-2
- US West (N. California) – us-west-1
- US West (Oregon) – us-west-2
- Asia Pacific (Mumbai) – ap-south-1
- Asia Pacific (Seoul) – ap-northeast-2
- Asia Pacific (Singapore) – ap-southeast-1
- Asia Pacific (Sydney) – ap-southeast-2

- Asia Pacific (Tokyo) – ap-northeast-1
- Canada (Central) – ca-central-1
- China (Beijing) – cn-north-1
- China (Ningxia) – cn-northwest-1
- Europe (Frankfurt) – eu-central-1
- Europe (Ireland) – eu-west-1
- Europe (London) – eu-west-2
- Europe (Paris) – eu-west-3
- Europe (Stockholm) – eu-north-1
- South America (São Paulo) – sa-east-1

Retention period

S3 Storage Lens metrics are retained so that you can see historical trends and compare differences in your storage and activity over time. You can use Amazon S3 Storage Lens metrics for queries so that you can see historical trends and compare differences in your storage usage and activity over time.

All S3 Storage Lens metrics are retained for a period of 15 months. However, metrics are only available for queries for a specific duration, which depends on your [metrics selection](#). This duration can't be modified. Free metrics are available for queries for a 14-day period, and advanced metrics are available for queries for a 15-month period.

Metrics categories

Within the free and advanced tiers, S3 Storage Lens metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to advanced metrics and recommendations, you can enable additional cost-optimization and data-protection metrics that you can use to further reduce your S3 storage costs and ensure your data is protected. You can also enable activity metrics and detailed status-code metrics that you can use to improve the performance of application workflows.

The following list shows all of the free and advanced metric categories. For a complete list of the individual metrics included in each category, see [Metrics glossary](#).

Summary metrics

Summary metrics provide general insights about your S3 storage, including your total storage bytes and object count.

Cost-optimization metrics

Cost-optimization metrics provide insights that you can use to manage and optimize your storage costs. For example, you can identify buckets that have incomplete multipart uploads that are more than 7-days old.

With advanced metrics and recommendations, you can enable advanced cost-optimization metrics. These metrics include S3 Lifecycle rule count metrics that you can use to get per-bucket expiration and transition S3 Lifecycle rule counts.

Data-protection metrics

Data-protection metrics provide insights for data-protection features, such as encryption and S3 Versioning. You can use these metrics to identify buckets that are not following data-protection best practices. For example, you can identify buckets that are not using default encryption with AWS Key Management Service keys (SSE-KMS) or S3 Versioning.

With advanced metrics and recommendations, you can enable advanced data-protection metrics. These metrics include per-bucket replication rule count metrics.

Access-management metrics

Access-management metrics provide insights for S3 Object Ownership. You can use these metrics to see which Object Ownership settings your buckets use.

Event metrics

Event metrics provide insights for S3 Event Notifications. With event metrics, you can see which buckets have S3 Event Notifications configured.

Performance metrics

Performance metrics provide insights for S3 Transfer Acceleration. With performance metrics, you can see which buckets have Transfer Acceleration enabled.

Activity metrics (advanced)

If you upgrade your dashboard to **Advanced metrics and recommendations**, you can enable activity metrics. Activity metrics provide details about how your storage is requested (for example, All requests, Get requests, Put requests), Bytes uploaded or downloaded, and errors.

Prefix-level activity metrics can be used to help you determine which prefixes are being used infrequently, so that you can [transition to a more optimal storage class using S3 Lifecycle](#).

Detailed status code metrics (advanced)

If you upgrade your dashboard to **Advanced metrics and recommendations**, you can enable detailed status code metrics. Detailed status code metrics provide insights for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable, that you can use to troubleshoot access or performance issues. For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied.

Prefix-level detailed status code metrics can be used to gain a better understanding of the HTTP status code occurrences by prefix. For example, 503 error count metrics enable you to identify prefixes receiving throttling requests during data ingestion.

Recommendations

S3 Storage Lens provides automated recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the S3 Storage Lens dashboard. Historical data is not eligible for recommendations because recommendations are relevant to what is happening in the most recent period. Recommendations appear only when they are relevant.

S3 Storage Lens recommendations come in the following forms:

- **Suggestions**

Suggestions alert you to trends within your storage and activity that might indicate a storage-cost optimization opportunity or a data-protection best practice. You can use the suggested topics in the *Amazon S3 User Guide* and the S3 Storage Lens dashboard to drill down for more details about the specific Regions, buckets, or prefixes.

- **Call-outs**

Call-outs are recommendations that alert you to interesting anomalies within your storage and activity over a period that might need further attention or monitoring.

- **Outlier call-outs**

S3 Storage Lens provides call-outs for metrics that are outliers, based on your recent 30-day trend. The outlier is calculated by using a standard score, also known as a *z-score*. In this score, the current day's metric is subtracted from the average of the last 30 days for that metric. The current day's metric is then divided by the standard deviation for that metric over the last 30 days. The resulting score is usually between -3 and +3. This number represents the number of standard deviations that the current day's metric is from the mean.

S3 Storage Lens considers metrics with a score >2 or <-2 to be outliers because they are higher or lower than 95 percent of normally distributed data.

- **Significant change call-outs**

The significant change call-out applies to metrics that are expected to change less frequently. Therefore, it is set to a higher sensitivity than the outlier calculation, which is typically in the range of +/- 20 percent versus the prior day, week, or month.

Addressing call-outs in your storage and activity – If you receive a significant change call-out, it's not necessarily a problem. The call-out could be the result of an anticipated change in your storage. For example, you might have recently added a large number of new objects, deleted a large number of objects, or made similar planned changes.

If you see a significant change call-out on your dashboard, take note of it and determine whether it can be explained by recent circumstances. If not, use the S3 Storage Lens dashboard to drill down for more details to understand the specific Regions, buckets, or prefixes that are driving the fluctuation.

- **Reminders**

Reminders provide insights into how Amazon S3 works. They can help you learn more about ways to use S3 features to reduce storage costs or apply data-protection best practices.

Metrics selection

S3 Storage Lens offers two metrics selections that you can choose for your dashboard and export: *free metrics* and *advanced metrics and recommendations*.

- **Free metrics**

S3 Storage Lens offers free metrics for all dashboards and configurations. Free metrics contain metrics that are relevant to your storage, such as the number of buckets and the objects in your

account. Free metrics also include use-case based metrics (for example, cost-optimization and data-protection metrics) that you can use to investigate whether your storage is configured according to S3 best practices. All free metrics are collected daily. Data is available for queries for 14 days. For more information about which metrics are available with free metrics, see the [Amazon S3 Storage Lens metrics glossary](#).

- **Advanced metrics and recommendations**

S3 Storage Lens offers free metrics for all dashboards and configurations with the option to upgrade to advanced metrics and recommendations. Additional charges apply. For more information, see [Amazon S3 pricing](#).

Advanced metrics and recommendations include all the metrics in free metrics along with additional metrics, such as advanced data-protection and cost-optimization metrics, activity metrics, and detailed status-code metrics. Advanced metrics and recommendations also provide recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the dashboard.

Advanced metrics and recommendations include the following features:

- **Advanced metrics** – Generate additional metrics. For a complete list of advanced metric categories, see [Metrics categories](#). For a complete list of metrics, see the [Amazon S3 Storage Lens metrics glossary](#).
- **Amazon CloudWatch publishing** – Publishes S3 Storage Lens metrics to CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). You can also use CloudWatch API operations and features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. For more information, see [Monitor S3 Storage Lens metrics in CloudWatch](#).
- **Prefix aggregation** – Collects metrics at the [prefix](#) level. Enabling prefix aggregation extends all metrics that are included in your dashboard configuration at the prefix level. Metrics are only generated for prefixes that meet the configured threshold. Note that metrics that are applicable at the prefix level are available with **Prefix aggregation**, except for bucket-level settings and rule count metrics. Prefix-level metrics are not published to CloudWatch.
- **Storage Lens group aggregation** – Collects metrics at the Storage Lens group level. After you enable **Advanced metrics and recommendations** and **Storage Lens group aggregation**, you can specify which Storage Lens groups to include or exclude from your Storage Lens dashboard. At least one Storage Lens group must be specified. Storage Lens groups that are

specified must also reside within the designated home Region in the dashboard account.

Storage Lens group-level metrics are not published to CloudWatch.

All advanced metrics are collected daily. Data is available for querying for up to 15 months. For more information about the storage metrics that are aggregated by S3 Storage Lens, see [Amazon S3 Storage Lens metrics glossary](#).

 **Note**

Recommendations are available only when you use the S3 Storage Lens dashboard on the Amazon S3 console.

S3 Storage Lens and AWS Organizations

AWS Organizations is an AWS service that helps you aggregate all of your AWS accounts under one organization hierarchy. Amazon S3 Storage Lens works with AWS Organizations to provide a single view of object storage and activity across your Amazon S3 storage.

For more information, see [Using Amazon S3 Storage Lens with AWS Organizations](#).

- **Trusted access**

Using your organization's management account, you must enable *trusted access* for S3 Storage Lens to aggregate storage metrics and usage data for all member accounts in your organization. You can then create dashboards or exports for your organization by using your management account or by giving delegated administrator access to other accounts in your organization.

You can disable trusted access for S3 Storage Lens at any time, which stops S3 Storage Lens from aggregating metrics for your organization.

- **Delegated administrator**

You can create dashboards and metrics for S3 Storage Lens for your organization by using your AWS Organizations management account, or by giving *delegated administrator* access to other accounts in your organization. You can deregister delegated administrators at any time. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

For more information, see [Amazon S3 Storage Lens and AWS Organizations](#) in the *AWS Organizations User Guide*.

Amazon S3 Storage Lens service-linked roles

Along with AWS Organizations trusted access, Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens and include all the permissions that it requires to collect daily storage and activity metrics from member accounts in your organization.

For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).

Using Amazon S3 Storage Lens with AWS Organizations

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

You can use Amazon S3 Storage Lens to collect storage metrics and usage data for all AWS accounts that are part of your AWS Organizations hierarchy. To do this, you must be using AWS Organizations, and you must enable S3 Storage Lens trusted access by using your AWS Organizations management account.

After enabling trusted access, you can add delegated administrator access to accounts in your organization. These accounts can then create S3 Storage Lens configurations and dashboards that collect organization-wide storage metrics and user data.

For more information about enabling trusted access, see [Amazon S3 Storage Lens and AWS Organizations](#) in the *AWS Organizations User Guide*.

Topics

- [Enabling trusted access for S3 Storage Lens](#)
- [Disabling trusted access for S3 Storage Lens](#)
- [Registering a delegated administrator for S3 Storage Lens](#)
- [Deregistering a delegated administrator for S3 Storage Lens](#)

Enabling trusted access for S3 Storage Lens

By enabling trusted access, you allow Amazon S3 Storage Lens to have access to your AWS Organizations hierarchy, membership, and structure through AWS Organizations API operations. S3 Storage Lens then becomes a trusted service for your entire organization's structure.

Whenever a dashboard configuration is created, S3 Storage Lens creates service-linked roles in your organization's management or delegated administrator accounts. The service-linked role grants S3 Storage Lens permission to do the following:

- Describe organizations
- List accounts
- Verify a list of AWS service access for the organizations
- Get delegated administrators for the organizations

S3 Storage Lens can then ensure that it has access to collect the cross-account metrics for the accounts in your organizations. For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).

After enabling trusted access, you can assign delegated administrator access to accounts in your organization. When an account is marked as a delegated administrator for a service, the account receives authorization to access all read-only organization API operations. This access provides the delegated administrator visibility to the members and structures of your organization so that they too can create S3 Storage Lens dashboards.

 **Note**

Only the management account can enable trusted access for Amazon S3 Storage Lens.

Disabling trusted access for S3 Storage Lens

By disabling trusted access, you limit S3 Storage Lens to working only on an account level. In addition, each account holder can see only the S3 Storage Lens information for the scope of their account, and not their entire organization. Any dashboards that require trusted access are no longer updated, but will retain their historic data for the period that [data is available for queries](#).

Note

- Disabling trusted access for S3 Storage Lens also automatically stops all organization-level dashboards from collecting and aggregating storage metrics.
- Your management and delegated administrator accounts will still be able to see the historic data for your existing organization-level dashboards during the period that data is available for queries.

Registering a delegated administrator for S3 Storage Lens

You can create organization-level dashboards by using your organization's management account or delegated administrator accounts. Delegated administrator accounts allow other accounts besides your management account to create organization-level dashboards. Only the management account of an organization can register and deregister other accounts as delegated administrators for the organization.

To register a delegated administrator by using the Amazon S3 console, see [Registering delegated administrators for S3 Storage Lens](#).

You can also register a delegated administrator by using the AWS Organizations REST API, AWS CLI, or SDKs from the management account. For more information, see [RegisterDelegatedAdministrator](#) in the *AWS Organizations API Reference*.

Note

Before you can designate a delegated administrator by using the AWS Organizations REST API, AWS CLI, or SDKs, you must call the [EnableAWSOrganizationsAccess](#) operation.

Deregistering a delegated administrator for S3 Storage Lens

You can also deregister a delegated administrator account. Delegated administrator accounts allow other accounts besides your management account to create organization-level dashboards. Only the management account of an organization can deregister accounts as delegated administrators for the organization.

To deregister a delegated administrator by using the S3 console, see [Deregistering delegated administrators for S3 Storage Lens](#).

You can also deregister a delegated administrator by using the AWS Organizations REST API, AWS CLI, or SDKs from the management account. For more information, see [DeregisterDelegatedAdministrator](#) in the *AWS Organizations API Reference*.

Note

- Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.
- The deregistered delegated administrator will still be able to see the historic data for the dashboards that they created while data is available for queries.

Amazon S3 Storage Lens permissions

Amazon S3 Storage Lens requires new permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to enable or disable S3 Storage Lens, or to access any S3 Storage Lens dashboard or configuration.

The IAM user or role must belong to the account that created or owns the dashboard or configuration, unless both of the following conditions are true:

- Your account is a member of AWS Organizations.
- You were given access to create organization-level dashboards by your management account as a delegated administrator.

Note

- You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required IAM permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see [Security best practices in IAM](#) in the *IAM User Guide*.
- Using S3 Storage Lens on the Amazon S3 console can require multiple permissions. For example, to edit a dashboard on the console, you need the following permissions:
 - `s3>ListStorageLensConfigurations`
 - `s3:GetStorageLensConfiguration`
 - `s3:PutStorageLensConfiguration`

Topics

- [Setting account permissions to use S3 Storage Lens](#)
- [Setting account permissions to use S3 Storage Lens groups](#)
- [Setting permissions to use S3 Storage Lens with AWS Organizations](#)

Setting account permissions to use S3 Storage Lens

To create and manage S3 Storage Lens dashboards and Storage Lens dashboard configurations, you must have the following permissions, depending on which actions you want to perform:

Amazon S3 Storage Lens related IAM permissions

Action	IAM permissions
Create or update an S3 Storage Lens dashboard in the Amazon S3 console.	<code>s3>ListStorageLensConfigurations</code> <code>s3:GetStorageLensConfiguration</code> <code>s3:GetStorageLensConfigurationTagging</code> <code>s3:PutStorageLensConfiguration</code>

Action	IAM permissions
	s3:PutStorageLensConfigurationTagging
Get the tags of an S3 Storage Lens dashboard on the Amazon S3 console.	s3>ListStorageLensConfigurations s3:GetStorageLensConfigurationTagging
View an S3 Storage Lens dashboard on the Amazon S3 console.	s3>ListStorageLensConfigurations s3:GetStorageLensConfiguration s3:GetStorageLensDashboard
Delete an S3 Storage Lens dashboard on Amazon S3 console.	s3>ListStorageLensConfigurations s3:GetStorageLensConfiguration s3>DeleteStorageLensConfiguration
Create or update an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3:PutStorageLensConfiguration s3:PutStorageLensConfigurationTagging
Get the tags of an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3:GetStorageLensConfigurationTagging
View an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3:GetStorageLensConfiguration
Delete an S3 Storage Lens configuration by using the AWS CLI or AWS SDK.	s3>DeleteStorageLensConfiguration

 **Note**

- You can use resource tags in an IAM policy to manage permissions.

- An IAM user or role with these permissions can see metrics from buckets and prefixes that they might not have direct permission to read or list objects from.
- For S3 Storage Lens dashboards with prefix-level metrics enabled, if a selected prefix path matches with an object key, the dashboard might display the object key as another prefix.
- For metrics exports, which are stored in a bucket in your account, permissions are granted by using the existing `s3:GetObject` permission in the IAM policy. Similarly, for an AWS Organizations entity, the organization's management account or delegated administrator accounts can use IAM policies to manage access permissions for organization-level dashboard and configurations.

Setting account permissions to use S3 Storage Lens groups

You can use S3 Storage Lens groups to understand the distribution of your storage within buckets based on prefix, suffix, object tag, object size, or object age. You can attach Storage Lens groups to your dashboards to view their aggregated metrics.

To work with Storage Lens groups, you need certain permissions. For more information, see [the section called "Storage Lens groups permissions"](#).

Setting permissions to use S3 Storage Lens with AWS Organizations

You can use Amazon S3 Storage Lens to collect storage metrics and usage data for all accounts that are part of your AWS Organizations hierarchy. The following are the actions and permissions related to using S3 Storage Lens with Organizations.

AWS Organizations related IAM permissions for using S3 Storage Lens

Action	IAM Permissions
Enable trusted access for S3 Storage Lens for your organization.	<code>organizations:EnableAWSServiceAccess</code>
Disable trusted access for S3 Storage Lens for your organization.	<code>organizations:DisableAWSServiceAccess</code>

Action	IAM Permissions
Register a delegated administrator to create S3 Storage Lens dashboards or configurations for your organization.	organizations:RegisterDelegatedAdministrator
Deregister a delegated administrator so that they can no longer create S3 Storage Lens dashboards or configurations for your organization.	organizations:DeregisterDelegatedAdministrator
Additional permissions to create S3 Storage Lens organization-wide configurations.	organizations:DescribeOrganization organizations>ListAccounts organizations>ListAWSServiceAccessForOrganization organizations>ListDelegatedAdministrators iam>CreateServiceLinkedRole

Viewing metrics with Amazon S3 Storage Lens

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

By default, all dashboards are configured with free metrics, which include metrics that you can use to understand usage and activity across your S3 storage, optimize your storage costs, and implement data-protection and access-management best practices. Free metrics are aggregated down to the bucket level. With free metrics, data is available for queries for up to 14 days.

Advanced metrics and recommendations include the following additional features that you can use to gain further insight into usage and activity across your storage and best practices for optimizing your storage:

- Contextual recommendations (available only in the dashboard)
- Advanced metrics (including activity metrics aggregated by bucket)
- Prefix aggregation
- Storage Lens group aggregation
- Storage Lens group aggregation
- Amazon CloudWatch publishing

Advanced metrics data is available for queries for 15 months. There are additional charges for using S3 Storage Lens with advanced metrics. For more information, see [Amazon S3 pricing](#). For more information about free and advanced metrics, see [Metrics selection](#).

Topics

- [Viewing S3 Storage Lens metrics on the dashboards](#)
- [Viewing Amazon S3 Storage Lens metrics using a data export](#)
- [Monitor S3 Storage Lens metrics in CloudWatch](#)

Viewing S3 Storage Lens metrics on the dashboards

In the Amazon S3 console, S3 Storage Lens provides an interactive default dashboard that you can use to visualize insights and trends in your data. You can also use this dashboard to flag outliers and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate insights at the account, bucket, AWS Region, prefix, or Storage Lens group level. If you've enabled S3 Storage Lens to work with AWS Organizations, you can also generate insights at the organization level (such as data for all accounts that are part of your AWS Organizations hierarchy). The dashboard always loads for the latest date that has metrics available.

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. Amazon S3 pre-configures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from the free metrics to the

paid advanced metrics and recommendations. With advanced metrics and recommendations, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing.

You can disable the default dashboard, but you can't delete it. If you disable your default dashboard, it is no longer updated. You also will no longer receive any new daily metrics in S3 Storage Lens or in the **Account snapshot** section on the **Buckets** page. You can still see historic data in the default dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics and recommendations. To access this data, you can re-enable the default dashboard within the expiration period.

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts. You can also scope your dashboards by organization if you've enabled Storage Lens to work with AWS Organizations. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

You can disable or delete any additional dashboards that you create.

- If you disable a dashboard, it is no longer updated, and you will no longer receive any new daily metrics. You can still see historic data for free metrics until the 14-day expiration period. If you enabled advanced metrics and recommendations for that dashboard, this period is 15 months. To access this data, you can re-enable the dashboard within the expiration period.
- If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

Topics

- [Viewing an Amazon S3 Storage Lens dashboard](#)
- [Understanding your S3 Storage Lens dashboard](#)

Viewing an Amazon S3 Storage Lens dashboard

The following procedure shows how to view an S3 Storage Lens dashboard in the S3 console. For use-case based walkthroughs that show how to use your dashboard to optimize costs, implement best practices, and improve the performance of applications that access your S3 buckets, see [Amazon S3 Storage Lens metrics use cases](#).

Note

You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required AWS Identity and Access Management (IAM) permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see [Amazon S3 Storage Lens permissions](#) and [Security best practices in IAM](#) in the *IAM User Guide*.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

Your dashboard opens in S3 Storage Lens. The **Snapshot for date** section shows the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads the latest date that has metrics available.

4. (Optional) To change the date for your S3 Storage Lens dashboard, in the top-right date selector, choose a new date.
5. (Optional) To apply temporary filters to further limit the scope of your dashboard data, do the following:
 - a. Expand the **Filters** section.
 - b. To filter by specific accounts, AWS Regions, storage classes, buckets, prefixes, or Storage Lens groups, choose the options to filter by.

Note

The **Prefixes** filter and the **Storage Lens groups** filter can't be applied at the same time.

- c. To update a filter, choose **Apply**.
- d. To remove a filter, click on the X next to the filter.
6. In any section in your S3 Storage Lens dashboard, to see data for a specific metric, for **Metric**, choose the metric name.

7. In any chart or visualization in your S3 Storage Lens dashboard, you can drill down into deeper levels of aggregation by using the **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes**, or **Storage Lens groups** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

Understanding your S3 Storage Lens dashboard

Your S3 Storage Lens dashboard has a primary **Overview** tab, and up to five additional tabs that represent each aggregation level:

- **Accounts**
- **AWS Regions**
- **Storage classes**
- **Buckets**
- **Prefixes**
- **Storage Lens groups**

On the **Overview** tab, your dashboard data is aggregated into three different sections: **Snapshot for date**, **Trends and distributions**, and **Top N overview**.

For more information about your S3 Storage Lens dashboard, see the following sections.

Snapshot

The **Snapshot for date** section shows summary metrics that S3 Storage Lens has aggregated for the date selected. These summary metrics include the following metrics:

- **Total storage** – The total amount of storage used in bytes.
- **Object count** – The total number of objects in your AWS account.
- **Average object size** – The average object size.
- **Active buckets** – The total number of active buckets in active usage with storage > 0 bytes in your account.
- **Accounts** – The number of accounts whose storage is in scope. This value is **1** unless you are using AWS Organizations and your S3 Storage Lens has trusted access with a valid service-linked role. For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).
- **Buckets** – The total number of buckets in your account.

Metric data

For each metric that appears in the snapshot, you can see the following data:

- **Metric name** – The name of the metric.
- **Metric category** – The category that the metric is organized into.
- **Total for date** – The total count for the date selected.
- **% change** – The percentage change from the last snapshot date.
- **30-day trend** – A trend-line showing the changes for the metric over a 30-day period.
- **Recommendation** – A contextual recommendation based on the data that's provided in the snapshot. Recommendations are available with advanced metrics and recommendations. For more information, see [Recommendations](#).

Metrics categories

You can optionally update your dashboard **Snapshot for date** section to display metrics for other categories. If you want to see snapshot data for additional metrics, you can choose from the following **Metrics categories**:

- **Cost optimization**
- **Data protection**
- **Activity** (available with advanced metrics)
- **Access management**
- **Performance**
- **Events**

The **Snapshot for date** section displays only a selection of metrics for each category. To see all metrics for a specific category, choose the metric in the **Trends and distributions** or **Top N overview** sections. For more information about metric categories, see [Metrics categories](#). For a complete list of S3 Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Trends and distributions

The second section of the **Overview** tab is **Trends and distributions**. In the **Trends and distributions** section, you can choose two metrics to compare over a date range that you define. The **Trends and distributions** section shows the relationship between two metrics over time. This

section displays charts that you can use to see the **Storage class** and **Region** distribution between the two trends that you are tracking. You can optionally drill down into a data point in one of the charts for deeper analysis.

For a walkthrough that uses the **Trends and distributions** section, see [Identify buckets that don't use server-side encryption with AWS KMS for default encryption \(SSE-KMS\)](#).

Top N overview

The third section of the S3 Storage Lens dashboard is **Top N overview** (sorted in ascending or descending order). This section displays your selected metrics across the top number of accounts, AWS Regions, buckets, prefixes, or Storage Lens groups. If you enabled S3 Storage Lens to work with AWS Organizations, you can also see your selected metrics across your organization.

For a walkthrough that uses the **Top N overview** section, see [Identify your largest S3 buckets](#).

Drill down and analyze by options

To provide a fluid experience for analysis, the S3 Storage Lens dashboard provides an action menu, which appears when you choose any chart value. To use this menu, choose any chart value to see the associated metrics values, and then choose from two options in the box that appears:

- The **Drill down** action applies the selected value as a filter across all tabs of your dashboard. You can then drill down into that value for deeper analysis.
- The **Analyze by** action takes you to the **Dimension** tab that you select and applies that tab value as a filter. These tabs include **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes** (for dashboards that have **Advanced metrics** and **Prefix aggregation** enabled), and **Storage Lens groups** (for dashboards that have **Advanced metrics** and **Storage Lens group aggregation** enabled). With **Analyze by**, you can view the data in the context of the new dimension for deeper analysis.

The **Drill down** and **Analyze by** actions might be disabled if the outcome would yield illogical results or would not have any value. Both the **Drill down** and **Analyze by** actions apply filters on top of any existing filters across all tabs of the dashboard. You can also remove the filters as needed.

Tabs

The dimension-level tabs provide a detailed view of all values within a particular dimension. For example, the **AWS Regions** tab shows metrics for all AWS Regions, and the **Buckets** tab shows metrics for all buckets. Each dimension tab contains an identical layout consisting of four sections:

- A trend chart that displays your top N items within the dimension over the last 30 days for the selected metric. By default, this chart displays the top 10 items, but you can decrease it to at least 3 items or increase it up to 50 items.
- A histogram chart that shows a vertical bar chart for the selected date and metric. If you have a large number of items to display in this chart, you might need to scroll horizontally.
- A bubble analysis chart that plots all items within the dimension. This chart represents the first metric on the x axis and the second metric on the y axis. The third metric is represented by the size of the bubble.
- A metric grid view that contains each item in the dimension listed in rows. The columns represent each available metric, arranged in metrics category tabs for easier navigation.

Viewing Amazon S3 Storage Lens metrics using a data export

Amazon S3 Storage Lens metrics are generated daily in CSV or Apache Parquet-formatted metrics export files and placed in an S3 bucket in your account. From there, you can ingest the metrics export into the analytics tools of your choice, such as Amazon QuickSight and Amazon Athena, where you can analyze storage usage and activity trends.

Topics

- [Using an AWS KMS key to encrypt your metrics exports](#)
- [What is an S3 Storage Lens export manifest?](#)
- [Understanding the Amazon S3 Storage Lens export schema](#)

Using an AWS KMS key to encrypt your metrics exports

To grant Amazon S3 Storage Lens permission to encrypt your metrics exports by using a customer managed key, you must use a key policy. To update your key policy so that you can use a KMS key to encrypt your S3 Storage Lens metrics exports, follow these steps.

To grant S3 Storage Lens permissions to encrypt data by using your KMS key

1. Sign into the AWS Management Console by using the AWS account that owns the customer managed key.
2. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
3. To change the AWS Region, use the **Region selector** in the upper-right corner of the page.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the key that you want to use to encrypt the metrics exports. AWS KMS keys are Region-specific and must be in the same Region as the metrics export destination S3 bucket.
6. Under **Key policy**, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. Under **Edit key policy**, add the following key policy to the existing key policy. To use this policy, replace the *user input placeholders* with your information.

```
{  
    "Sid": "Allow Amazon S3 Storage Lens use of the KMS key",  
    "Effect": "Allow",  
    "Principal": {  
        "Service": "storage-lens.s3.amazonaws.com"  
    },  
    "Action": [  
        "kms:GenerateDataKey"  
    ],  
    "Resource": "*",  
    "Condition": {  
        "StringEquals": {  
            "aws:SourceArn": "arn:aws:s3:us-east-1:source-account-id:storage-  
lens/your-dashboard-name",  
            "aws:SourceAccount": "source-account-id"  
        }  
    }  
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following topics in the *AWS Key Management Service Developer Guide*:

- [Getting started](#)
- [Using key policies in AWS KMS](#)

You can also use the AWS KMS PUT key policy API operation ([PutKeyPolicy](#)) to copy the key policy to the customer managed keys that you want to use to encrypt the metrics exports by using the REST API, AWS CLI, and SDKs.

What is an S3 Storage Lens export manifest?

Given the large amount of data aggregated, an S3 Storage Lens daily metrics export can be split into multiple files. The manifest file `manifest.json` describes where the metrics export files for that day are located. Whenever a new export is delivered, it is accompanied by a new manifest. Each manifest contained in the `manifest.json` file provides metadata and other basic information about the export.

The manifest information includes the following properties:

- `sourceAccountId` – The account ID of the configuration owner.
- `configId` – A unique identifier for the dashboard.
- `destinationBucket` – The destination bucket Amazon Resource Name (ARN) that the metrics export is placed in.
- `reportVersion` – The version of the export.
- `reportDate` – The date of the report.
- `reportFormat` – The format of the report.
- `reportSchema` – The schema of the report.
- `reportFiles` – The actual list of the export report files that are in the destination bucket.

The following is an example of a manifest in a `manifest.json` file for a CSV-formatted export.

```
{  
  "sourceAccountId": "123456789012",  
  "configId": "my-dashboard-configuration-id",  
  "destinationBucket": "arn:aws:s3:::destination-bucket",  
  "reportVersion": "V_1",  
  "reportDate": "2020-11-03",  
  "files": [  
    {  
      "file": "file1.csv",  
      "format": "CSV",  
      "schema": "S3Object",  
      "version": "V_1"  
    },  
    {  
      "file": "file2.csv",  
      "format": "CSV",  
      "schema": "S3Object",  
      "version": "V_1"  
    }  
  ]  
}
```

```
"reportFormat": "CSV",  
  
"reportSchema": "version_number,configuration_id,report_date,aws_account_number,aws_region,stor  
"reportFiles": [  
    {  
        "key": "DestinationPrefix/StorageLens/123456789012/my-dashboard-  
configuration-id/V_1/reports/dt=2020-11-03/a38f6bc4-2e3d-4355-ac8a-e2fdcf3de158.csv",  
        "size": 1603959,  
        "md5Checksum": "2177e775870def72b8d84febe1ad3574"  
    }  
]  
}
```

The following is an example of a manifest in a `manifest.json` file for a Parquet-formatted export.

```
{  
    "sourceAccountId": "123456789012",  
    "configId": "my-dashboard-configuration-id",  
    "destinationBucket": "arn:aws:s3:::destination-bucket",  
    "reportVersion": "V_1",  
    "reportDate": "2020-11-03",  
    "reportFormat": "Parquet",  
    "reportSchema": "message s3.storage.lens { required string version_number;  
required string configuration_id; required string report_date; required string  
aws_account_number; required string aws_region; required string storage_class;  
required string record_type; required string record_value; required string  
bucket_name; required string metric_name; required long metric_value; }",  
    "reportFiles": [  
        {  
            "key": "DestinationPrefix/StorageLens/123456789012/my-dashboard-configuration-  
id/V_1/reports/dt=2020-11-03/bd23de7c-b46a-4cf4-bcc5-b21aac5be0f5.par",  
            "size": 14714,  
            "md5Checksum": "b5c741ee0251cd99b90b3e8eff50b944"  
        }  
    ]  
}
```

You can configure your metrics export to be generated as part of your dashboard configuration in the Amazon S3 console or by using the Amazon S3 REST API, AWS CLI, and SDKs.

Understanding the Amazon S3 Storage Lens export schema

The following table contains the schema of your S3 Storage Lens metrics export.

Attribute name	Data type	Column name	Description
VersionNumber	String	version_number	The version of the S3 Storage Lens metrics being used.
ConfigurationId	String	configuration_id	The configuration_id of your S3 Storage Lens configuration.
ReportDate	String	report_date	The date that the metrics were tracked.
AwsAccountNumber	String	aws_account_number	Your AWS account number.
AwsRegion	String	aws_region	The AWS Region for which the metrics are being tracked.
StorageClass	String	storage_class	The storage class of the bucket in question.
RecordType	ENUM	record_type	The type of artifact that is being reported (ACCOUNT, BUCKET, or PREFIX).
RecordValue	String	record_value	The value of the RecordType artifact.

 **Note**

The record_va

Attribute name	Data type	Column name	Description
			Value is URL-encoded.
BucketName	String	bucket_name	The name of the bucket that is being reported.
MetricName	String	metric_name	The name of the metric that is being reported.
MetricValue	Long	metric_value	The value of the metric that is being reported.

Example of an S3 Storage Lens metrics export

The following is an example of an S3 Storage Lens metrics export based on this schema.

Note

You can identify metrics for Storage Lens groups by looking for the STORAGE_LENS_GROUP_BUCKET or STORAGE_LENS_GROUP_ACCOUNT values in the record_type column. The record_value column will display the Amazon Resource Name (ARN) for the Storage Lens group, for example, arn:aws:s3:us-east-1:123456789012:storage-lens-group/slgl-1.

version_r	configuration_id	report_date	aws_account_number	aws_region	storage_class	record_type	record_value	bucket_name	metric_name	metric_value

The following is an example of an S3 Storage Lens metrics export with Storage Lens groups data.

Monitor S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, and AWS SDKs. Dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations can use the CloudWatch publishing option. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see [Amazon CloudWatch pricing](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

 **Note**

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

After you enable the CloudWatch publishing option, you can use the following CloudWatch features to monitor and analyze your S3 Storage Lens data:

- [Dashboards](#) – Use CloudWatch dashboards to create customized S3 Storage Lens dashboards. Share your CloudWatch dashboard with people who don't have direct access to your AWS account, across teams, with stakeholders, and with people external to your organizations.
- [Alarms and triggered actions](#) – Configure alarms that watch metrics and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.
- [Anomaly detection](#) – Enable anomaly detection to continuously analyze metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on

the expected value of a metric. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.

- [Metric math](#) – You can also use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric to get the average object size by dividing `StorageBytes` by `ObjectCount`.

For more information about the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

Topics

- [S3 Storage Lens metrics and dimensions](#)
- [Enabling CloudWatch publishing for S3 Storage Lens](#)
- [Working with S3 Storage Lens metrics in CloudWatch](#)

S3 Storage Lens metrics and dimensions

To send S3 Storage Lens metrics to CloudWatch, you must enable the CloudWatch publishing option within S3 Storage Lens advanced metrics and recommendations. After advanced metrics are enabled, you can use [CloudWatch dashboards](#) to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. You can use dimensions to filter your S3 Storage Lens metrics in CloudWatch by organization, account, bucket, storage class, Region, and metrics configuration ID.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for

S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

For more information about S3 Storage Lens metrics and dimensions in CloudWatch, see the following topics.

Topics

- [Metrics](#)
- [Dimensions](#)

Metrics

S3 Storage Lens metrics are available as metrics within CloudWatch. S3 Storage Lens metrics are published to the AWS/S3/Storage-Lens namespace. This namespace is only for S3 Storage Lens metrics. Amazon S3 bucket, request, and replication metrics are published to the AWS/S3 namespace.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

In S3 Storage Lens, metrics are aggregated and stored only in the designated home Region. S3 Storage Lens metrics are also published to CloudWatch in the home Region that you specify in the S3 Storage Lens configuration.

For a complete list of S3 Storage Lens metrics, including a list of those metrics available in CloudWatch, see [Amazon S3 Storage Lens metrics glossary](#).

Note

The valid statistic for S3 Storage Lens metrics in CloudWatch is Average. For more information about statistics in CloudWatch, see [CloudWatch statistics definitions in the Amazon CloudWatch User Guide](#).

Granularity of S3 Storage Lens metrics in CloudWatch

S3 Storage Lens offers metrics at organization, account, bucket, and prefix granularity. S3 Storage Lens publishes organization, account, and bucket-level S3 Storage Lens metrics to CloudWatch. Prefix-level S3 Storage Lens metrics are not available in CloudWatch.

For more information about the granularity of S3 Storage Lens metrics available in CloudWatch, see the following list:

- **Organization** – Metrics aggregated across the member accounts in your organization. S3 Storage Lens publishes metrics for member accounts to CloudWatch in the management account.
 - **Organization and account** – Metrics for the member accounts in your organization.
 - **Organization and bucket** – Metrics for Amazon S3 buckets in the member accounts of your organization.
- **Account** (Non-organization level) – Metrics aggregated across the buckets in your account.
- **Bucket** (Non-organization level) – Metrics for a specific bucket. In CloudWatch, S3 Storage Lens publishes these metrics to the AWS account that created the S3 Storage Lens configuration. S3 Storage Lens publishes these metrics only for non-organization configurations.

Dimensions

When S3 Storage Lens sends data to CloudWatch, dimensions are attached to each metric.

Dimensions are categories that describe the characteristics of metrics. You can use dimensions to filter the results that CloudWatch returns.

For example, all S3 Storage Lens metrics in CloudWatch have the `configuration_id` dimension. You can use this dimension to differentiate between metrics associated with a specific S3 Storage Lens configuration. The `organization_id` identifies organization-level metrics. For more information about dimensions in CloudWatch, see [Dimensions](#) in the *CloudWatch User Guide*.

Different dimensions are available for S3 Storage Lens metrics depending on the granularity of the metrics. For example, you can use the `organization_id` dimension to filter organization-level metrics by the AWS Organizations ID. However, you can't use this dimension for bucket and account-level metrics. For more information, see [Filtering metrics using dimensions](#).

To see which dimensions are available for your S3 Storage Lens configuration, see the following table.

Dimension	Description	Bucket	Organization	Account	Bucket and account	Bucket count
configuration_id	The dashboard name for the S3 Storage Lens configuration reported in the metrics	*	*	*	*	*
metrics_version	The version of the S3 Storage Lens metrics. The metrics version has a fixed value of 1.0.	*	*	*	*	*
organization_id	The AWS Organizations ID for the metrics	*	*	*	*	*
aws_account_number	The AWS account that's associated with the metrics	*	*	*	*	*
aws_region	The AWS Region for the metrics	*	*	*	*	*
bucket_name	The name of the S3 bucket that's reported in the metrics	*	*	*	*	*
storage_class	The storage class for the bucket that's reported in the metrics	*	*	*	*	*
record_type	The granularity of the metrics: ORGANIZATION, ACCOUNT, BUCKET	BUCKET	BUCKET	ACCOUNT	BUCKET AND ACCOUNT	ORGANIZATION

Enabling CloudWatch publishing for S3 Storage Lens

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications,

including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

You can enable CloudWatch support for new or existing dashboard configurations by using the S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply.

To enable the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

Using the S3 console

When you update an S3 Storage Lens dashboard, you can't change the dashboard name or home Region. You also can't change the scope of the default dashboard, which is scoped to your entire account's storage.

To update an S3 Storage Lens dashboard to enable CloudWatch publishing

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **S3 Storage Lens, Dashboards**.
3. Choose the dashboard that you want to edit, and then choose **Edit**.
4. Under **Metrics selection**, choose **Advanced metrics and recommendations**.

Advanced metrics and recommendations are available for an additional charge. Advanced metrics and recommendations include a 15-month period for data queries, usage metrics aggregated at the prefix level, activity metrics aggregated by bucket, the CloudWatch publishing option, and contextual recommendations that help you optimize storage costs and apply data-protection best practices. For more information, see [Amazon S3 pricing](#).

5. Under **Select Advanced metrics and recommendations features**, select **CloudWatch publishing**.

⚠ Important

If your configuration enables prefix aggregation for usage metrics, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

6. Choose **Save changes**.

To create a new S3 Storage Lens dashboard that enables CloudWatch support

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. Choose **Create dashboard**.
4. Under **General**, define the following configuration options:
 - a. For **Dashboard name**, enter your dashboard name.

Dashboard names must be fewer than 65 characters and must not contain special characters or spaces. You can't change the dashboard name after you create your dashboard.
 - b. Choose the **Home Region** for your dashboard.

Metrics for all Regions included in this dashboard scope are stored centrally in the designated home Region. In CloudWatch, S3 Storage Lens metrics are also available in the home Region. You can't change the home Region after you create your dashboard.

5. (Optional) To add tags, choose **Add tag** and enter the tag **Key** and **Value**.

 **Note**

You can add up to 50 tags to your dashboard configuration.

6. Define the scope for your configuration:

- a. If you're creating an organization-level configuration, choose the accounts to include in the configuration: **Include all accounts in your configuration** or **Limit the scope to your signed-in account**.

 **Note**

When you create an organization-level configuration that includes all accounts, you can include or exclude only Regions, not buckets.

- b. Choose the Regions and buckets that you want S3 Storage Lens to include in the dashboard configuration by doing the following:
 - To include all Regions, choose **Include Regions and buckets**.
 - To include specific Regions, clear **Include all Regions**. Under **Choose Regions to include**, choose the Regions that you want S3 Storage Lens to include in the dashboard.
 - To include specific buckets, clear **Include all buckets**. Under **Choose buckets to include**, choose the buckets that you want S3 Storage Lens to include in the dashboard.

 **Note**

You can choose up to 50 buckets.

7. For **Metrics selection**, choose **Advanced metrics and recommendations**.

For more information about advanced metrics and recommendations pricing, see [Amazon S3 pricing](#).

8. Under **Advanced metrics and recommendations features**, select the options that you want to enable:

- **Advanced metrics**
- **CloudWatch publishing**

 **Important**

If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

- **Prefix aggregation**

 **Note**

For more information about advanced metrics and recommendations features, see [Metrics selection](#).

9. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

- **Activity metrics**
- **Detailed status code metrics**
- **Advanced cost optimization metrics**
- **Advanced data protection metrics**

For more information about metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

10. (Optional) Configure your metrics export.

For more information about how to configure a metrics export, see step [Creating an Amazon S3 Storage Lens dashboard](#).

11. Choose **Create dashboard**.

Using the AWS CLI

The following AWS CLI example enables the CloudWatch publishing option by using a S3 Storage Lens organization-level advanced metrics and recommendations configuration. To use this example, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=555555555555 --config-id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./config.json

config.json

    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Using the REST API

To enable the CloudWatch publishing option by using the Amazon S3 REST API, you can use [PutStorageLensConfiguration](#).

Next steps

After you enable the CloudWatch publishing option, you can access your S3 Storage Lens metrics in CloudWatch. You also can leverage CloudWatch features to monitor and analyze your S3 Storage Lens data in CloudWatch. For more information, see the following topics:

- [S3 Storage Lens metrics and dimensions](#)
- [Working with S3 Storage Lens metrics in CloudWatch](#)

Working with S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see [Amazon CloudWatch pricing](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must

be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

For more information about working with S3 Storage Lens metrics in CloudWatch, see the following topics.

Topics

- [Working with CloudWatch dashboards](#)
- [Setting alarms, triggering actions, and using anomaly detection](#)
- [Filtering metrics using dimensions](#)
- [Calculating new metrics with metric math](#)
- [Using search expressions in graphs](#)

Working with CloudWatch dashboards

You can use CloudWatch dashboards to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view.

CloudWatch has broad permissions control that doesn't support limiting access to a specific set of metrics or dimensions. Users in your account or organization who have access to CloudWatch will have access to metrics for all S3 Storage Lens configurations where the CloudWatch support option is enabled. You can't manage permissions for specific dashboards as you can in S3 Storage Lens. For more information about CloudWatch permissions, see [Managing access permissions to your CloudWatch resources](#) in the *Amazon CloudWatch User Guide*.

For more information about using CloudWatch dashboards and configuring permissions, see [Using Amazon CloudWatch dashboards](#) and [Sharing CloudWatch dashboards](#) in the *Amazon CloudWatch User Guide*.

Setting alarms, triggering actions, and using anomaly detection

You can configure CloudWatch alarms that watch S3 Storage Lens metrics in CloudWatch and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.

You can also enable anomaly detection to continuously analyze your S3 Storage Lens metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on a metric's expected value. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.

For more information and examples, see [Using Amazon CloudWatch alarms](#) and [Creating an alarm from a metric on a graph](#) in the *Amazon CloudWatch User Guide*.

Filtering metrics using dimensions

You can use dimensions to filter S3 Storage Lens metrics in the CloudWatch console. For example, you can filter by `configuration_id`, `aws_account_number`, `aws_region`, `bucket_name`, and more.

S3 Storage Lens supports multiple dashboard configurations per account. This means that different configurations can include the same bucket. When these metrics are published to CloudWatch, the bucket will have duplicate metrics within CloudWatch. To view metrics only for a specific S3 Storage Lens configuration in CloudWatch, you can use the `configuration_id` dimension. When you filter by `configuration_id`, you see only the metrics that are associated with the configuration that you identify.

For more information about filtering by configuration ID, see [Searching for available metrics](#) in the *Amazon CloudWatch User Guide*.

Calculating new metrics with metric math

You can use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric for unencrypted objects by subtracting Encrypted Objects from Object Count. You can also create a metric to get the average object size by dividing `StorageBytes` by `ObjectCount` or the number bytes accessed on one day by dividing `BytesDownloaded` by `StorageBytes`.

For more information, see [Using metric math](#) in the *Amazon CloudWatch User Guide*.

Using search expressions in graphs

With S3 Storage Lens metrics, you can create a search expression. For example, you can create a search expression for all metrics that are named **IncompleteMultipartUploadStorageBytes** and add SUM to the expression. With this search expression, you can see your total incomplete multipart upload bytes across all dimensions of your storage in a single metric.

This example shows the syntax that you would use to create a search expression for all metrics named **IncompleteMultipartUploadStorageBytes**.

```
SUM(SEARCH( '{AWS/S3/Storage-  
Lens,aws_account_number,aws_region,configuration_id,metrics_version,record_type,storage_class}  
MetricName="IncompleteMultipartUploadStorageBytes"', 'Average',86400))
```

For more information about this syntax, see [CloudWatch search expression syntax](#) in the *Amazon CloudWatch User Guide*. To create a CloudWatch graph with a search expression, see [Creating a CloudWatch graph with a search expression](#) in the *Amazon CloudWatch User Guide*.

Amazon S3 Storage Lens metrics use cases

You can use your Amazon S3 Storage Lens dashboard to visualize insights and trends, flag outliers, and receive recommendations. S3 Storage Lens metrics are organized into categories that align with key use cases. You can use these metrics to do the following:

- Identify cost-optimization opportunities
- Apply data-protection best practices
- Apply access-management best practices
- Improve the performance of application workloads

For example, with cost-optimization metrics, you can identify opportunities to reduce your Amazon S3 storage costs. You can identify buckets with multipart uploads that are more than 7-days old or buckets that are accumulating noncurrent versions.

Similarly, you can use data-protection metrics to identify buckets that aren't following data-protection best practices within your organization. For example, you can identify buckets that don't use AWS Key Management Service keys (SSE-KMS) for default encryption or don't have S3 Versioning enabled.

With S3 Storage Lens access-management metrics, you can identify bucket settings for S3 Object Ownership so that you can migrate access control list (ACL) permissions to bucket policies and disable ACLs.

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use detailed status-code metrics to get counts for successful or failed requests that you can use to troubleshoot access or performance issues.

With advanced metrics, you can also access additional cost-optimization and data-protection metrics that you can use to identify opportunities to further reduce your overall S3 storage costs and better align with best practices for protecting your data. For example, advanced cost-optimization metrics include lifecycle rule counts that you can use to identify buckets that don't have lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. Advanced data-protection metrics include replication rule counts.

For more information about metrics categories, see [Metrics categories](#). For a complete list of S3 Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Topics

- [Using Amazon S3 Storage Lens to optimize your storage costs](#)
- [Using S3 Storage Lens to protect your data](#)
- [Using S3 Storage Lens to audit Object Ownership settings](#)
- [Using S3 Storage Lens metrics to improve performance](#)

Using Amazon S3 Storage Lens to optimize your storage costs

You can use S3 Storage Lens cost-optimization metrics to reduce the overall cost of your S3 storage. Cost-optimization metrics can help you confirm that you've configured Amazon S3 cost effectively and according to best practices. For example, you can identify the following cost-optimization opportunities:

- Buckets with incomplete multipart uploads older than 7 days
- Buckets that are accumulating numerous noncurrent versions
- Buckets that don't have lifecycle rules to abort incomplete multipart uploads
- Buckets that don't have lifecycle rules to expire noncurrent versions objects
- Buckets that don't have lifecycle rules to transition objects to a different storage class

You can then use this data to add additional lifecycle rules to your buckets.

The following examples show how you can use cost- optimization metrics in your S3 Storage Lens dashboard to optimize your storage costs.

Topics

- [Identify your largest S3 buckets](#)
- [Uncover cold Amazon S3 buckets](#)
- [Locate incomplete multipart uploads](#)
- [Reduce the number of noncurrent versions retained](#)
- [Identify buckets that don't have lifecycle rules and review lifecycle rule counts](#)

Identify your largest S3 buckets

You pay for storing objects in S3 buckets. The rate that you're charged depends on your objects' sizes, how long you store the objects, and their storage classes. With S3 Storage Lens, you get a centralized view of all the buckets in your account. To see all the buckets in all of your organization's accounts, you can configure an AWS Organizations-level S3 Storage Lens dashboard. From this dashboard view, you can identify your largest buckets.

Step 1: Identify your largest buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

When the dashboard opens, you can see the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads to the latest date that has metrics available.

4. To see a ranking of your largest buckets by the **Total storage** metric for a selected date range, scroll down to the **Top N overview for date** section.

You can toggle the sort order to show the smallest buckets. You can also adjust the **Metric** selection to rank your buckets by any of the available metrics. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For more detailed insights about your buckets, scroll up to the top of the page, and then choose the **Bucket** tab.

On the **Bucket** tab, you can see details such as the recent growth rate, the average object size, the largest prefixes, and the number of objects.

Step 2: Navigate to your buckets and investigate

After you've identified your largest S3 buckets, you can navigate to each bucket within the S3 console to view the objects in the bucket, understand its associated workload, and identify its internal owners. You can contact the bucket owners to find out whether the growth is expected or whether the growth needs further monitoring and control.

Uncover cold Amazon S3 buckets

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use [activity metrics](#) to understand how cold your S3 buckets are. A "cold" bucket is one whose storage is no longer accessed (or very rarely accessed). This lack of activity typically indicates that the bucket's objects aren't frequently accessed.

Activity metrics, such as **GET Requests** and **Download Bytes**, indicate how often your buckets are accessed each day. To understand the consistency of the access pattern and to spot buckets that are no longer being accessed at all, you can trend this data over several months. The **Retrieval rate** metric, which is computed as **Download bytes / Total storage**, indicates the proportion of storage in a bucket that is accessed daily.

Note

Download bytes are duplicated in cases where the same object is downloaded multiple times during the day.

Prerequisite

To see activity metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Activity metrics**. For more information, see [Creating and updating Amazon S3 Storage Lens dashboards](#).

Step 1: Identify active buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. Choose the **Bucket** tab, and then scroll down to the **Bubble analysis by buckets for date** section.

In the **Bubble analysis by buckets for date** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.

5. To find buckets that have gone cold, for **X-axis**, **Y-axis**, and **Size**, choose the **Total storage**, **% retrieval rate**, and **Average object size** metrics.
6. In the **Bubble analysis by buckets for date** section, locate any buckets with retrieval rates of zero (or near zero) and a larger relative storage size, and choose the bubble that represents the bucket.

A box will appear with choices for more granular insights. Do one of the following:

- a. To update the **Bucket** tab to display metrics only for the selected bucket, choose **Drill down**, and then choose **Apply**.
- b. To aggregate your bucket-level data to by account, AWS Region, storage class, or bucket, choose **Analyze by** and then make a choice for **Dimension**. For example, to aggregate by storage class, choose **Storage class** for **Dimension**.

To find buckets that have gone cold, do a bubble analysis using the **Total storage**, **% retrieval rate**, and **Average object size** metrics. Look for any buckets with retrieval rates of zero (or near zero) and a larger relative storage size.

The **Bucket** tab of your dashboard updates to display data for your selected aggregation or filter. If you aggregated by storage class or another dimension, that new tab opens in your dashboard (for example, the **Storage class** tab).

Step 2: Investigate cold buckets

From here, you can identify the owners of cold buckets in your account or organization and find out if that storage is still needed. You can then optimize costs by configuring [lifecycle expiration configurations](#) for these buckets or archiving the data in one of the [Amazon S3 Glacier storage classes](#).

To avoid the problem of cold buckets going forward, you can [automatically transition your data by using S3 Lifecycle configurations](#) for your buckets, or you can enable [auto-archiving with S3 Intelligent-Tiering](#).

You can also use step 1 to identify hot buckets. Then, you can ensure that these buckets use the correct [S3 storage class](#) to ensure that they serve their requests most effectively in terms of performance and cost.

Locate incomplete multipart uploads

You can use multipart uploads to upload very large objects (up to 5 TB) as a set of parts for improved throughput and quicker recovery from network issues. In cases where the multipart upload process doesn't finish, the incomplete parts remain in the bucket (in an unusable state). These incomplete parts incur storage costs until the upload process is finished, or until the incomplete parts are removed. For more information, see [Uploading and copying objects using multipart upload](#).

With S3 Storage Lens, you can identify the number of incomplete multipart upload bytes in your account or across your entire organization, including incomplete multipart uploads that are more than 7 days old. For a complete list of incomplete multipart upload metrics, see [Amazon S3 Storage Lens metrics glossary](#).

As a best practice, we recommend configuring lifecycle rules to expire incomplete multipart uploads that are older than a specific number of days. When you create your lifecycle rule to expire incomplete multipart uploads, we recommend 7 days as a good starting point.

Step 1: Review overall trends for incomplete multipart uploads

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

4. In the **Snapshot for date** section, under **Metrics categories**, choose **Cost optimization**.

The **Snapshot for date** section updates to display **Cost optimization** metrics, which include **Incomplete multipart upload bytes greater than 7 days old**.

In any chart in your S3 Storage Lens dashboard, you can see metrics for incomplete multipart uploads. You can use these metrics to further assess the impact of incomplete multipart upload bytes on your storage, including their contribution to overall growth trends. You can also drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Bucket**, or **Storage class** tabs for a deeper analysis of your data. For an example, see [Uncover cold Amazon S3 buckets](#).

Step 2: Identify buckets that have the most incomplete multipart upload bytes but don't have lifecycle rules to abort incomplete multipart uploads

Prerequisite

To see the **Abort incomplete multipart upload lifecycle rule count** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Creating and updating Amazon S3 Storage Lens dashboards](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets that are accumulating incomplete multipart uploads greater than 7 days old, go to the **Top N overview for date** section.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. You can increase or decrease the number of buckets in the **Top N** field. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. (This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.)

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For **Metric**, choose **Incomplete multipart upload bytes greater than 7 days old** in the **Cost optimization** category.

Under **Top *number* buckets**, you can see the buckets with the most incomplete multipart upload storage bytes that are greater than 7 days old.

6. To view more detailed bucket-level metrics for incomplete multipart uploads, scroll to the top of the page, and then choose the **Bucket** tab.
7. Scroll down to the **Buckets** section. For **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

8. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
9. Clear the toggles for all cost-optimization metrics until only **Incomplete multipart upload bytes greater than 7 days old** and **Abort incomplete multipart upload lifecycle rule count** remain selected.
10. (Optional) Under **Page size**, choose the number of buckets to display in the list.
11. Choose **Confirm**.

The **Buckets** list updates to display bucket-level metrics for incomplete multipart uploads and lifecycle rule counts. You can use this data to identify buckets that have the most incomplete multipart upload bytes that are greater than 7 days old and are missing lifecycle rules to abort incomplete multipart uploads. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to delete abandoned incomplete multipart uploads.

Step 3: Add a lifecycle rule to delete incomplete multipart uploads after 7 days

To automatically manage incomplete multipart uploads, you can use the S3 console to create a lifecycle configuration to expire incomplete multipart upload bytes from a bucket after a specified number of days. For more information, see [Configuring a bucket lifecycle configuration to delete incomplete multipart uploads](#).

Reduce the number of noncurrent versions retained

When enabled, S3 Versioning retains multiple distinct copies of the same object that you can use to quickly recover data if an object is accidentally deleted or overwritten. If you've enabled S3 Versioning without configuring lifecycle rules to transition or expire noncurrent versions, a large number of previous noncurrent versions can accumulate, which can have storage-cost implications. For more information, see [Using versioning in S3 buckets](#).

Step 1: Identify buckets with the most noncurrent object versions

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for date** section, under **Metric categories**, choose **Cost optimization**.

The **Snapshot for date** section updates to display **Cost optimization** metrics, which include the metric for **% noncurrent version bytes**. The **% noncurrent version bytes** metric represents the proportion of your total storage bytes that is attributed to noncurrent versions, within the dashboard scope and for the selected date.

 **Note**

If your **% noncurrent version bytes** is greater than 10 percent of your storage at the account level, you might be storing too many object versions.

5. To identify specific buckets that are accumulating a large number of noncurrent versions:
 - a. Scroll down to the **Top N overview for date** section. For **Top N**, enter the number of buckets that you would like to see data for.
 - b. For **Metric**, choose **% noncurrent version bytes**.

Under **Top number buckets**, you can see the buckets (for the number that you specified) with the highest % **noncurrent version bytes**. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

 **Note**

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

- c. To view more detailed bucket-level metrics for noncurrent object versions, scroll to the top of the page, and then choose the **Bucket** tab.

In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

- d. In the **Buckets** section, for **Metric categories**, select **Cost optimization**. Then, clear **Summary**.

You can now see the % **noncurrent version bytes** metric, along with other metrics related to noncurrent versions.

Step 2: Identify buckets that are missing transition and expiration lifecycle rules for managing noncurrent versions

Prerequisite

To see the **Noncurrent version transition lifecycle rule count** and **Noncurrent version expiration lifecycle rule count** metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Creating and updating Amazon S3 Storage Lens dashboards](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:
 - **% noncurrent version bytes**
 - **Noncurrent version transition lifecycle rule count**
 - **Noncurrent version expiration lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display metrics for noncurrent version bytes and noncurrent version lifecycle rule counts. You can use this data to identify buckets that have a high percentage of noncurrent version bytes but are missing transition and expiration lifecycle rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules to transition or expire noncurrent object versions

After you've determined which buckets require further investigation, you can navigate to the buckets within the S3 console and add a lifecycle rule to expire noncurrent versions after a specified number of days. Alternatively, to reduce costs while still retaining noncurrent versions, you can configure a lifecycle rule to transition noncurrent versions to one of the Amazon S3 Glacier storage classes. For more information, see [Example 6: Specifying a lifecycle rule for a versioning-enabled bucket](#).

Identify buckets that don't have lifecycle rules and review lifecycle rule counts

S3 Storage Lens provides S3 Lifecycle rule count metrics that you can use to identify buckets that are missing lifecycle rules. To find buckets that don't have lifecycle rules, you can use the **Total**

buckets without lifecycle rules metric. A bucket with no S3 Lifecycle configuration might have storage that you no longer need or can migrate to a lower-cost storage class. You can also use lifecycle rule count metrics to identify buckets that are missing specific types of lifecycle rules, such as expiration or transition rules.

Prerequisite

To see lifecycle rule count metrics and the **Total buckets without lifecycle rules** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Creating and updating Amazon S3 Storage Lens dashboards](#).

Step 1: Identify buckets without lifecycle rules

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets without lifecycle rules, scroll down to the **Top N overview for date** section.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For **Metric**, choose **Total buckets without lifecycle rules** from the **Cost optimization** category.
6. Review the following data for **Total buckets without lifecycle rules**:
 - **Top number accounts** - See which accounts that have the most buckets without lifecycle rules.
 - **Top number Regions** - View a breakdown of buckets without lifecycle rules by Region.

- **Top number buckets** - See which buckets don't have lifecycle rules.

In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

After you identify which buckets don't have lifecycle rules, you can also review specific lifecycle rule counts for your buckets.

Step 2: Review lifecycle rule counts for your buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your S3 Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:
 - **Transition lifecycle rule count**
 - **Expiration lifecycle rule count**
 - **Noncurrent version transition lifecycle rule count**
 - **Noncurrent version expiration lifecycle rule count**
 - **Abort incomplete multipart upload lifecycle rule count**
 - **Total lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display lifecycle rule count metrics for your buckets. You can use this data to identify buckets without lifecycle rules or buckets that are missing specific kinds of lifecycle rules, for example, expiration or transition rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules

After you've identified buckets with no lifecycle rules, you can add lifecycle rules. For more information, see [Setting lifecycle configuration on a bucket](#) and [Examples of S3 Lifecycle configuration](#).

Using S3 Storage Lens to protect your data

You can use Amazon S3 Storage Lens data-protection metrics to identify buckets where data-protection best practices haven't been applied. You can use these metrics to take action and apply standard settings that align with best practices for protecting your data across the buckets in your account or organization. For example, you can use data-protection metrics to identify buckets that don't use AWS Key Management Service (AWS KMS) keys (SSE-KMS) for default encryption or requests that use AWS Signature Version 2 (SigV2).

The following use cases provide strategies for using your S3 Storage Lens dashboard to identify outliers and apply data-protection best practices across your S3 buckets.

Topics

- [Identify buckets that don't use server-side encryption with AWS KMS for default encryption \(SSE-KMS\)](#)
- [Identify buckets that have S3 Versioning enabled](#)
- [Identify requests that use AWS Signature Version 2 \(SigV2\)](#)
- [Count the total number of replication rules for each bucket](#)
- [Identify percentage of Object Lock bytes](#)

Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS)

With Amazon S3 default encryption, you can set the default encryption behavior for an S3 bucket. For more information, see [the section called "Setting default bucket encryption"](#).

You can use the **SSE-KMS enabled bucket count** and **% SSE-KMS enabled buckets** metrics to identify buckets that use server-side encryption with AWS KMS keys (SSE-KMS) for default encryption. S3 Storage Lens also provides metrics for unencrypted bytes, unencrypted objects, encrypted bytes, and encrypted objects. For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

You can analyze SSE-KMS encryption metrics in the context of general encryption metrics to identify buckets that don't use SSE-KMS. If you want to use SSE-KMS for all the buckets in your account or organization, you can then update the default encryption settings for these buckets to use SSE-KMS. In addition to SSE-KMS, you can use server-side encryption with Amazon S3 managed keys (SSE-S3) or customer-provided keys (SSE-C). For more information, see [Protecting data with encryption](#).

Step 1: Identify which buckets are using SSE-KMS for default encryption

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **% SSE-KMS enabled bucket count** for the primary metric and **% encrypted bytes** for the secondary metric.

The **Trend for date** chart updates to display trends for SSE-KMS and encrypted bytes.

5. To view more granular, bucket-level insights for SSE-KMS:
 - a. Choose a point on the chart. A box will appear with choices for more granular insights.
 - b. Choose the **Buckets** dimension. Then choose **Apply**.
6. In the **Distribution by buckets for date** chart, choose the **SSE-KMS enabled bucket count** metric.
7. You can now see which buckets have SSE-KMS enabled and which do not.

Step 2: Update bucket default encryption settings

Now that you've determined which buckets use SSE-KMS in the context of your **% encrypted bytes**, you can identify buckets that don't use SSE-KMS. You can then optionally navigate to these buckets within the S3 console and update their default encryption settings to use SSE-KMS or SSE-S3. For more information, see [Configuring default encryption](#).

Identify buckets that have S3 Versioning enabled

When enabled, the S3 Versioning feature retains multiple versions of the same object that can be used to quickly recover data if an object is accidentally deleted or overwritten. You can use the **Versioning-enabled bucket count** metric to see which buckets use S3 Versioning. Then, you can take action in the S3 console to enable S3 Versioning for other buckets.

Step 1: Identify buckets that have S3 Versioning enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **Versioning-enabled bucket count** for the primary metric and **Buckets** for the secondary metric.

The **Trend for date** chart updates to display trends for S3 Versioning enabled buckets. Right below the trends line, you can see the **Storage class distribution** and **Region distribution** subsections.

5. To view more granular insights for any of the buckets that you see in the **Trend for date** chart so that you can perform a deeper analysis, do the following:
 - a. Choose a point on the chart. A box will appear with choices for more granular insights.
 - b. Choose a dimension to apply to your data for deeper analysis: **Account**, **AWS Region**, **Storage class**, or **Bucket**. Then choose **Apply**.
6. In the **Bubble analysis by buckets for date** section, choose the **Versioning-enabled bucket count**, **Buckets**, and **Active buckets** metrics.

The **Bubble analysis by buckets for date** section updates to display data for the metrics that you selected. You can use this data to see which buckets have S3 Versioning enabled in the context of your total bucket count. In the **Bubble analysis by buckets for date** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.

Step 2: Enable S3 Versioning

After you've identified buckets that have S3 Versioning enabled, you can identify buckets that have never had S3 Versioning enabled or are versioning suspended. Then, you can optionally enable

versioning for these buckets in the S3 console. For more information, see [Enabling versioning on buckets](#).

Identify requests that use AWS Signature Version 2 (SigV2)

You can use the **All unsupported signature requests** metric to identify requests that use AWS Signature Version 2 (SigV2). This data can help you identify specific applications that are using SigV2. You can then migrate these applications to AWS Signature Version 4 (SigV4).

SigV4 is the recommended signing method for all new S3 applications. SigV4 provides improved security and is supported in all AWS Regions. For more information, see [Amazon S3 update - SigV2 deprecation period extended & modified](#).

Prerequisite

To see **All unsupported signature requests** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see [Creating and updating Amazon S3 Storage Lens dashboards](#).

Step 1: Examine SigV2 signing trends by AWS account, Region, and bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To identify specific buckets, accounts, and Regions with requests that use SigV2:
 - a. Under **Top N overview for date**, in **Top N**, enter the number of buckets that you would like to see data for.
 - b. For **Metric**, choose **All unsupported signature requests** from the **Data protection** category.

The **Top N overview for date** updates to display data for SigV2 requests by account, AWS Region, and bucket. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

Step 2: Identify buckets that are accessed by applications through SigV2 requests

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Data protection** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific data-protection metrics, choose the preferences icon ).
7. Clear the toggles for all data-protection metrics until only the following metrics remain selected:
 - All unsupported signature requests
 - % all unsupported signature requests
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display bucket-level metrics for SigV2 requests. You can use this data to identify specific buckets that have SigV2 requests. Then, you can use this information to migrate your applications to SigV4. For more information, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

Count the total number of replication rules for each bucket

S3 Replication enables automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. For more information, see [Replicating objects](#).

You can use S3 Storage Lens replication rule count metrics to get detailed per-bucket information about your buckets that are configured for replication. This information includes replication rules within and across buckets and Regions.

Prerequisite

To see replication rule count metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see [Creating and updating Amazon S3 Storage Lens dashboards](#).

Step 1: Count the total number of replication rules for each bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.
6. To filter the **Buckets** list to display only replication rule count metrics, choose the preferences icon ).
7. Clear the toggles for all data-protection metrics until only the replication rule count metrics remain selected:
 - **Same-Region Replication rule count**
 - **Cross-Region Replication rule count**
 - **Same-account replication rule count**
 - **Cross-account replication rule count**
 - **Total replication rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.

9. Choose **Confirm**.

Step 2: Add replication rules

After you have a per-bucket replication rule count, you can optionally create additional replication rules. For more information, see [Walkthroughs: Examples for configuring replication](#).

Identify percentage of Object Lock bytes

With S3 Object Lock, you can store objects by using a *write-once-read-many (WORM)* model. You can use Object Lock to help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely. You can enable Object Lock only when you create a bucket and also enable S3 Versioning. However, you can edit the retention period for individual object versions or apply legal holds for buckets that have Object Lock enabled. For more information, see [Using S3 Object Lock](#).

You can use Object Lock metrics in S3 Storage Lens to see the **% Object Lock bytes** metric for your account or organization. You can use this information to identify buckets in your account or organization that aren't following your data-protection best practices.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot** section, under **Metrics categories**, choose **Data protection**.

The **Snapshot** section updates to display data-protection metrics, including the **% Object Lock bytes** metric. You can see the overall percentage of Object Lock bytes for your account or organization.

5. To see the **% Object Lock bytes** per bucket, scroll down to the **Top N overview** section.

To get object-level data for Object Lock, you can also use the **Object Lock object count** and **% Object Lock objects** metrics.

6. For **Metric**, choose **% Object Lock bytes** from the **Data protection** category.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the

trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

 **Note**

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

7. Review the following data for **% Object Lock bytes**:

- **Top *number* accounts** - See which accounts have the highest and lowest **% Object Lock bytes**.
- **Top *number* Regions** - View a breakdown of **% Object Lock bytes** by Region.
- **Top *number* buckets** - See which buckets have the highest and lowest **% Object Lock bytes**.

Using S3 Storage Lens to audit Object Ownership settings

Amazon S3 Object Ownership is an S3 bucket-level setting that you can use to disable access control lists (ACLs) and control ownership of the objects in your bucket. If you set Object Ownership to bucket owner enforced, you can disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket. This approach simplifies access management for data stored in Amazon S3.

By default, when another AWS account uploads an object to your S3 bucket, that account (the object writer) owns the object, has access to it, and can grant other users access to it through ACLs. You can use Object Ownership to change this default behavior.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. Therefore, we recommend that you disable ACLs, except in unusual circumstances where you must control access for each object individually. By setting Object Ownership to bucket owner enforced, you can disable ACLs and rely on policies for access control. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

With S3 Storage Lens access-management metrics, you can identify buckets that don't have disabled ACLs. After identifying these buckets, you can migrate ACL permissions to policies and disable ACLs for these buckets.

Topics

- [Step 1: Identify general trends for Object Ownership settings](#)
- [Step 2: Identify bucket-level trends for Object Ownership settings](#)
- [Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs](#)

Step 1: Identify general trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot for date** section, under **Metrics categories**, choose **Access management**.

The **Snapshot for date** section updates to display the **% Object Ownership bucket owner enforced** metric. You can see the overall percentage of buckets in your account or organization that use the bucket owner enforced setting for Object Ownership to disable ACLs.

Step 2: Identify bucket-level trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To view more detailed bucket-level metrics, choose the **Bucket** tab.
5. In the **Distribution by buckets for date** section, choose the **% Object Ownership bucket owner enforced** metric.

The chart updates to show a per-bucket breakdown for **% Object Ownership bucket owner enforced**. You can see which buckets use the bucket owner enforced setting for Object Ownership to disable ACLs.

6. To view the bucket owner enforced settings in context, scroll down to the **Buckets** section. For **Metrics categories**, select **Access management**. Then clear **Summary**.

The **Buckets** list displays data for all three Object Ownership settings: bucket owner enforced, bucket owner preferred, and object writer.

7. To filter the **Buckets** list to display metrics only for a specific Object Ownership setting, choose the preferences icon ).
8. Clear the metrics that you don't want to see.
9. (Optional) Under **Page size**, choose the number of buckets to display in the list.
10. Choose **Confirm**.

Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs

After you've identified buckets that use the object writer and bucket owner preferred setting for Object Ownership, you can migrate your ACL permissions to bucket policies. When you've finished migrating your ACL permissions, you can then update your Object Ownership settings to bucket owner enforced in order to disable ACLs. For more information, see [Prerequisites for disabling ACLs](#).

Using S3 Storage Lens metrics to improve performance

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use detailed status-code metrics to get counts for successful or failed requests. You can use this information to troubleshoot access or performance issues. Detailed status-code metrics show counts for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable. You can examine overall trends for detailed status-code metrics across S3 buckets, accounts, and organizations. Then, you can drill down into bucket-level metrics to identify workloads that are currently accessing these buckets and causing errors.

For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied. After you've identified these workloads, you can do a deep dive outside of S3 Storage Lens to troubleshoot your 403 Forbidden errors.

This example shows you how to do a trend analysis for the 403 Forbidden error by using the **403 Forbidden error count** and the **% 403 Forbidden errors** metrics. You can use these metrics to identify workloads that are accessing buckets without the correct permissions applied. You can do a similar trend analysis for any of the other **Detailed status code metrics**. For more information, see [Amazon S3 Storage Lens metrics glossary](#).

Prerequisite

To see **Detailed status code metrics** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Detailed status code metrics**. For more information, see [Creating and updating Amazon S3 Storage Lens dashboards](#).

Topics

- [Step 1: Do a trend analysis for an individual HTTP status code](#)
- [Step 2: Analyze error counts by bucket](#)
- [Step 3: Troubleshoot errors](#)

Step 1: Do a trend analysis for an individual HTTP status code

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, for **Primary metric**, choose **403 Forbidden error count** from the **Detailed status codes** category. For **Secondary metric**, choose **% 403 Forbidden errors**.
5. Scroll down to the **Top N overview for date** section. For **Metrics**, choose **403 Forbidden error count** or **% 403 Forbidden errors** from the **Detailed status codes** category.

The **Top N overview for date** section updates to display the top 403 Forbidden error counts by account, AWS Region, and bucket.

Step 2: Analyze error counts by bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metrics categories**, select **Detailed status code metrics**. Then clear **Summary**.

The **Buckets** list updates to display all the available detailed status code metrics. You can use this information to see which buckets have a large proportion of certain HTTP status codes and which status codes are common across buckets.

6. To filter the **Buckets** list to display only specific detailed status-code metrics, choose the preferences icon ).
7. Clear the toggles for any detailed status-code metrics that you don't want to view in the **Buckets** list.
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list displays error count metrics for the number of buckets that you specified. You can use this information to identify specific buckets that are experiencing many errors and troubleshoot errors by bucket.

Step 3: Troubleshoot errors

After you identify buckets with a high proportion of specific HTTP status codes, you can troubleshoot these errors. For more information, see the following:

- [Why am I getting a 403 Forbidden error when I try to upload files in Amazon S3?](#)
- [Why am I getting a 403 Forbidden error when I try to modify a bucket policy in Amazon S3?](#)
- [How do I troubleshoot 403 Forbidden errors from my Amazon S3 bucket where all the resources are from the same AWS account?](#)
- [How do I troubleshoot an HTTP 500 or 503 error from Amazon S3?](#)

Amazon S3 Storage Lens metrics glossary

The Amazon S3 Storage Lens metrics glossary provides a complete list of free and advanced metrics for S3 Storage Lens.

S3 Storage Lens offers free metrics for all dashboards and configurations, with the option to upgrade to advanced metrics.

- **Free metrics** contain metrics that are relevant to your storage usage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics, such as cost-optimization and data-protection metrics. All free metrics are collected daily, and data is available for queries for up to 14 days.
- **Advanced metrics and recommendations** include all the metrics in free metrics along with additional metrics, such as advanced data-protection and cost-optimization metrics. Advanced metrics also include additional metric categories, such as activity metrics and detailed status-code metrics. Advanced metrics data is available for queries for 15 months.

There are additional charges when you use S3 Storage Lens with advanced metrics and recommendations. For more information, see [Amazon S3 pricing](#). For more information about advanced metrics and recommendations features, see [Metrics selection](#).

 **Note**

For Storage Lens groups, only free tier storage metrics are available. Advanced tier metrics are not available at the Storage Lens group level.

Metric names

The **Metric name** column in the following table provides the name of each S3 Storage Lens in the S3 console. The **CloudWatch and export** column provides the name of each metric in Amazon CloudWatch and the metrics export file that you can configure in your S3 Storage Lens dashboard.

Derived metric formulas

Derived metrics are not available for the metrics export and the CloudWatch publishing option. However, you can use the metrics formulas shown in the **Derived metrics formula** column to compute them.

Interpreting the Amazon S3 Storage Lens prefix symbols for metrics unit multiples (K, M, G, and so on)

S3 Storage Lens metrics unit multiples are written with prefix symbols. These prefix symbols match the International System of Units (SI) symbols that are standardized by the International Bureau of Weights and Measures (BIPM). These symbols are also used in the Unified Code for Units of Measure (UCUM). For more information, see [List of SI prefix symbols](#).

Note

- The unit of measurement for S3 storage bytes is in binary gigabytes (GB), where 1 GB is 2^{30} bytes, 1 TB is 2^{40} bytes, and 1 PB is 2^{50} bytes. This unit of measurement is also known as a gibibyte (GiB), as defined by the International Electrotechnical Commission (IEC).
- When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. S3 Storage Lens doesn't include metrics for objects that have expired but haven't been removed. For more information about expiration actions in S3 Lifecycle, see [Expiring objects](#).

S3 Storage Lens metrics glossary

Metric name	CloudWatch and export	Description	Tier ¹	Category	Derivation	Definition
Total storage	StorageBytes	The total storage, inclusive of incomplete multipart uploads, object metadata, and delete markers	Free	Sum	N	-
Object count	ObjectCount	The total object count	Free	Sum	N	-
Average object size	-	The average object size	Free	Sum	Y	$\text{sum(StorageBytes)}/\text{sum(ObjectCount)}$
Active buckets	-	The total number of buckets in	Free	Sum	Y	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
		active usage with storage > 0 bytes					
Buckets	-	The total number of buckets	Free	Sum	Y	-	
Accounts	-	The number of accounts whose storage is in scope	Free	Sum	Y	-	
Current version bytes	CurrentVersionStorageBytes	The number of bytes that are a current version of an object	Free	Cost optimization	N	-	
% current version bytes	-	The percentage of bytes in scope that are current versions of objects	Free	Cost optimization	Y	sum(CurrentVersionStorageBytes)/sum(StorageBytes)	
Current version object count	CurrentVersionObjectCount	The count of current version objects	Free	Cost optimization	N	-	
% current version objects	-	The percentage of objects in scope that are a current version	Free	Cost optimization	Y	sum(CurrentVersionObjectCount)/sum(ObjectCount)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric form
Noncurrent version bytes	NonCurrentVersionStorageBytes	The number of noncurrent version bytes	Free	Cost optimization	N	-
% noncurrent version bytes	-	The percentage of bytes in scope that are noncurrent versions	Free	Cost optimization	Y	$\text{sum}(\text{NonCurrentVersionStorageBytes}) / \text{sum}(\text{StorageBytes})$
Noncurrent version object count	NonCurrentVersionObjectCount	The count of the noncurrent object versions	Free	Cost optimization	N	-
% noncurrent version objects	-	The percentage of objects in scope that are a noncurrent version	Free	Cost optimization	Y	$\text{sum}(\text{NonCurrentVersionObjectCount}) / \text{sum}(\text{ObjectCount})$
Delete marker bytes	DeleteMarkerStorageBytes	The number of bytes in scope that are delete markers	Free	Cost optimization	N	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
% delete marker bytes	-	The percentage of bytes in scope that are delete markers	Free	Cost optimization	Y	sum(DeleteMarkerStorageBytes)/sum(StorageBytes)	
Delete marker object count	DeleteMarkerObjectCount	The total number of objects with a delete marker	Free	Cost optimization	N	-	
% delete marker objects	-	The percentage of objects in scope with a delete marker	Free	Cost optimization	Y	sum(DeleteMarkerObjectCount)/sum(ObjectCount)	
Incomplete multipart upload bytes	IncompleteMultipartUploadStorageBytes	The total bytes in scope for incomplete multipart uploads	Free	Cost optimization	N	-	
% incomplete multipart upload bytes	-	The percentage of bytes in scope that are the result of incomplete multipart uploads	Free	Cost optimization	Y	sum(IncompleteMultipartUploadStorageBytes)/sum(StorageBytes)

¹ All free tier storage metrics are available at the Storage Lens group level. Advanced tier metrics are not available at the Storage Lens group level.

² Rule count metrics and bucket settings metrics aren't available at the prefix level.

Working with Amazon S3 Storage Lens by using the console and API

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account,

AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

The following sections contain examples of creating, updating, and viewing S3 Storage Lens configurations and performing operations related to the feature. If you are using S3 Storage Lens with AWS Organizations, these examples also cover those use cases. In the examples, replace any variable values with those that are specific to you.

Creating and updating Amazon S3 Storage Lens dashboards

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

The Amazon S3 Storage Lens default dashboard is **default-account-dashboard**. This dashboard is preconfigured by Amazon S3 to help you visualize summarized insights and trends for your entire account's aggregated free and advanced metrics on the console. You can't modify the default dashboard's configuration scope, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations, configure the optional metrics export, or even disable the default dashboard. The default dashboard cannot be deleted.

You can also create additional S3 Storage Lens custom dashboards that can be scoped to your organization in AWS Organizations or to specific Regions or buckets within an account.

Creating an Amazon S3 Storage Lens dashboard

Use the following steps to create an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Define the dashboard scope

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, under **S3 Storage Lens**, choose **Dashboards**.
3. Choose **Create dashboard**.
4. On the **Dashboard** page, in the **General** section, do the following:
 - a. Enter a dashboard name.

Dashboard names must be fewer than 65 characters and must not contain special characters or spaces.

 **Note**

You can't change this dashboard name after the dashboard is created.

- b. Choose the **Home Region** for your dashboard. Your dashboard metrics for all included Regions in this dashboard scope are stored centrally in this designated home Region.
- c. You can optionally choose to add **Tags** to your dashboard. You can use tags to manage permissions for your dashboard and track costs for S3 Storage Lens.

For more information, see [Controlling access using resource tags](#) in the *IAM User Guide* and [AWS-Generated Cost Allocation Tags](#) in the *AWS Billing User Guide*.

 **Note**

You can add up to 50 tags to your dashboard configuration.

5. In the **Dashboard scope** section, do the following:
 - a. Choose the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.
 - b. Choose the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option is not available when you create organization-level dashboards.

Note

- You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
- You can choose up to 50 buckets to include or exclude.

Step 2: Configure the metrics selection

1. In the **Metrics selection** section, choose the type of metrics that you want to aggregate for this dashboard.
 - To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free metrics**.
 - To enable advanced metrics and other advanced options, choose **Advanced metrics and recommendations**. These options include advanced prefix aggregation, Amazon CloudWatch publishing, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see [Amazon S3 pricing](#).

For more information about advanced metrics and free metrics, see [Metrics selection](#).

2. Under **Advanced metrics and recommendations features**, select the options that you want to enable:
 - **Advanced metrics**
 - **CloudWatch publishing**
 - **Prefix aggregation**

⚠ Important

If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

3. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

- **Activity metrics**
- **Detailed status code metrics**
- **Advanced cost optimization metrics**
- **Advanced data protection metrics**

For more information about metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

4. If you chose to enable prefix aggregation, configure the following:

- a. Choose the minimum prefix threshold size for this dashboard.

For example, a prefix threshold of 5 percent indicates that prefixes that make up 5 percent or more of the bucket's total storage size will be aggregated.

- b. Choose the prefix depth.

This setting indicates the maximum number of levels up to which the prefixes are evaluated. The prefix depth must be less than 10.

- c. Enter a prefix delimiter character.

This value is used to identify each prefix level. The default value in Amazon S3 is the / character, but your storage structure might use other delimiter characters.

(Optional) Step 3: Export metrics for the dashboard

1. In the **Metrics export** section, to create a metrics export that will be placed daily in a destination bucket of your choice, choose **Enable**.

The metrics export is in CSV or Apache Parquet format. It represents the same scope of data as your S3 Storage Lens dashboard data without the recommendations.

2. If you enabled the metrics export, choose the output format of your daily metrics export: **CSV** or **Apache Parquet**.

Parquet is an open source file format for Hadoop that stores nested data in a flat columnar format.

3. Choose the destination S3 bucket for your metrics export.

You can choose a bucket in the current account of the S3 Storage Lens dashboard. Or you can choose another AWS account if you have the destination bucket permissions and the destination bucket owner's account ID.

4. Choose the destination S3 bucket (format: s3://*bucket-name/prefix*).

The bucket must be in the home Region of your S3 Storage Lens dashboard. The S3 console shows you the **Destination bucket permission** that will be added by Amazon S3 to the destination bucket policy. Amazon S3 updates the bucket policy on the destination bucket to allow S3 to place data in that bucket.

5. (Optional) To enable server-side encryption for your metrics export, choose **Specify an encryption key**. Then, choose the **Encryption type: Amazon S3 managed keys (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

You can choose between an [Amazon S3 managed key \(SSE-S3\)](#) and an [AWS Key Management Service \(AWS KMS\) key \(SSE-KMS\)](#).

6. (Optional) To specify an AWS KMS key, you must choose a KMS key or enter a key Amazon Resource Name (ARN).

If you choose a customer managed key, you must grant S3 Storage Lens permission to encrypt in the AWS KMS key policy. For more information, see [Using an AWS KMS key to encrypt your metrics exports](#)

7. Choose **Create dashboard**.

To gain further visibility into your storage, you can create one or more S3 Storage Lens groups and attach them to your dashboard. An S3 Storage Lens group is a custom defined filter for objects based on prefixes, suffixes, object tags, object size, object age, or a combination of these filters.

You can use S3 Storage Lens groups to gain granular visibility into large shared buckets, such as data lakes, to make better-informed business decisions. For example, you can streamline storage allocation and optimize cost reporting by breaking down storage usage to specific groups of objects for individual projects and cost centers within a bucket or across multiple buckets.

To use S3 Storage Lens groups, you must upgrade your dashboard to use advanced metrics and recommendations. For more information about S3 Storage Lens groups, see [the section called "Working with S3 Storage Lens groups"](#).

Updating an Amazon S3 Storage Lens dashboard

Use the following steps to update an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Update the dashboard scope

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. Choose the dashboard that you want to edit, and then choose **Edit**.

The **Edit dashboard** page opens.

Note

You can't change the following:

- The dashboard name
- The home Region
- The dashboard scope of the default dashboard, which is scoped to your entire account's storage

4. (Optional) On the dashboard configuration page, in the **General** section, update and add tags to your dashboard.

You can use tags to manage permissions for your dashboard and to track costs for S3 Storage Lens. For more information, see [Controlling access using resource tags](#) in the *IAM User Guide* and [AWS-Generated Cost Allocation Tags](#) in the *AWS Billing User Guide*.

Note

You can add up to 50 tags to your dashboard configuration.

5. In the **Dashboard scope** section, do the following:

- a. Update the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.

Note

- You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
- You can choose up to 50 buckets to include or exclude.

- b. Update the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option is not present when creating organization-level dashboards.

Step 2: Update the metrics selection

1. In the **Metrics selection** section, choose the type of metrics that you want to aggregate for this dashboard.
 - To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free metrics**.
 - To enable advanced metrics and other advanced options, choose **Advanced metrics and recommendations**. These options include advanced prefix aggregation, Amazon CloudWatch publishing, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see [Amazon S3 pricing](#).

For more information about advanced metrics and free metrics, see [Metrics selection](#).

2. Under **Advanced metrics and recommendations features**, select the options that you want to enable:
 - **Advanced metrics**
 - **CloudWatch publishing**
 - **Prefix aggregation**

⚠ Important

If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

3. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

- **Activity metrics**
- **Detailed status code metrics**
- **Advanced cost optimization metrics**
- **Advanced data protection metrics**

For more information metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

4. If you chose to enable prefix aggregation, configure the following:

- a. Choose the minimum prefix threshold size for this dashboard.

For example, a prefix threshold of 5 percent indicates that prefixes that make up 5 percent or more of the bucket's total storage size will be aggregated.

- b. Choose the prefix depth.

This setting indicates the maximum number of levels up to which the prefixes are evaluated. The prefix depth must be less than 10.

- c. Enter a prefix delimiter character.

This is the value used to identify each prefix level. The default value in Amazon S3 is the / character, but your storage structure might use other delimiter characters.

(Optional) Step 3: Export metrics for the dashboard

1. In the **Metrics export** section, to create a metrics export that will be placed daily in a destination bucket of your choice, choose **Enable**. To disable the metrics export, choose **Disable**.

The metrics export is in CSV or Apache Parquet format. It represents the same scope of data as your S3 Storage Lens dashboard data without the recommendations.

2. If enabled, choose the output format of your daily metrics export: **CSV** or **Apache Parquet**.

Parquet is an open source file format for Hadoop that stores nested data in a flat columnar format.

3. Choose the destination S3 bucket for your metrics export.

You can choose a bucket in the current account of the S3 Storage Lens dashboard. Or you can choose another AWS account if you have the destination bucket permissions and the destination bucket owner's account ID.

4. Choose the destination S3 bucket (format: s3://*bucket-name/prefix*).

The bucket must be in the home Region of your S3 Storage Lens dashboard. The S3 console shows you the **Destination bucket permission** that will be added by Amazon S3 to the destination bucket policy. Amazon S3 updates the bucket policy on the destination bucket to allow S3 to place data in that bucket.

5. (Optional) To enable server-side encryption for your metrics export, choose **Specify an encryption key**. Then, choose the **Encryption type**: **Amazon S3 managed keys (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

You can choose between an [Amazon S3 managed key](#) (SSE-S3) and an [AWS Key Management Service \(AWS KMS\)](#) key (SSE-KMS).

6. (Optional) To specify an AWS KMS key, you must choose a KMS key or enter a key Amazon Resource Name (ARN). Under **AWS KMS key**, specify your KMS key in one of the following ways:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the [AWS Key Management Service Developer Guide](#).

 **Note**

The AWS managed key (aws/S3) is not supported for SSE-KMS encryption with S3 Storage Lens.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

If you choose a customer managed key, you must grant S3 Storage Lens permission to encrypt in the AWS KMS key policy. For more information, see [Using an AWS KMS key to encrypt your metrics exports](#)

For more information about creating an AWS KMS key, see [Creating Keys](#) in the [AWS Key Management Service Developer Guide](#).

7. Choose **Save changes**.

To gain further visibility into your storage, you can create one or more S3 Storage Lens groups and attach them to your dashboard. An S3 Storage Lens group is a custom defined filter for objects based on prefixes, suffixes, object tags, object size, object age, or a combination of these filters.

You can use S3 Storage Lens groups to gain granular visibility into large shared buckets, such as data lakes, to make better-informed business decisions. For example, you can streamline storage allocation and optimize cost reporting by breaking down storage usage to specific groups of objects for individual projects and cost centers within a bucket or across multiple buckets.

To use S3 Storage Lens groups, you must upgrade your dashboard to use advanced metrics and recommendations. For more information about S3 Storage Lens groups, see [the section called "Working with S3 Storage Lens groups"](#).

Disabling or deleting Amazon S3 Storage Lens dashboards

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an

interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

The Amazon S3 Storage Lens default dashboard is **default-account-dashboard**. This dashboard is preconfigured by Amazon S3 to help you visualize summarized insights and trends for your entire account's aggregated free and advanced metrics on the console. You can't modify the default dashboard's configuration scope, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations, configure the optional metrics export, or even disable the default dashboard. The default dashboard cannot be deleted.

You can delete or disable an Amazon S3 Storage Lens dashboard from the Amazon S3 console. Disabling or deleting a dashboard prevents it from generating metrics in the future. A disabled dashboard still retains its configuration information, so that it can be easily resumed when re-enabled. A disabled dashboard retains its historical data until it's no longer available for queries.

Data for free metrics selections is available for queries for 14 days, and data for advanced metrics and recommendations selections is available for queries for 15 months.

Disabling an Amazon S3 Storage Lens dashboard

To disable an S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to disable, and then choose **Disable** at the top of the list.
4. On the confirmation page, confirm that you want to disable the dashboard by entering the name of dashboard in the text field, and then choose **Confirm**.

Deleting an Amazon S3 Storage Lens dashboard

Note

You can't delete the default dashboard. However, you can disable it. Before deleting a dashboard that you've created, consider the following:

- As an alternative to deleting a dashboard, you can *disable* the dashboard so that it is available to be re-enabled in the future. For more information, see [Disabling an Amazon S3 Storage Lens dashboard](#).
- Deleting the dashboard deletes all the configuration settings that are associated with it.
- Deleting a dashboard makes all the historic metrics data unavailable. This historical data is still retained for 15 months. If you want to access this data again, create a dashboard with the same name in the same home Region as the one that was deleted.

To delete an S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to delete, and then choose **Delete** at the top of the list.
4. On the **Delete dashboards** page, confirm that you want to delete the dashboard by entering the name of dashboard in the text field. Then choose **Confirm**.

Working with AWS Organizations to create organization-level dashboards

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

The Amazon S3 Storage Lens default dashboard is **default-account-dashboard**. This dashboard is preconfigured by Amazon S3 to help you visualize summarized insights and trends for your entire account's aggregated free and advanced metrics on the console. You can't modify the default dashboard's configuration scope, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations, configure the optional metrics export, or even disable the default dashboard. The default dashboard cannot be deleted.

You can also create additional S3 Storage Lens dashboards that are focused on specific AWS Regions, S3 buckets, or other AWS accounts in your organization.

An S3 Storage Lens dashboard provides a rich resource of information about its storage scope. A dashboard visualizes more than 30 metrics that represent trends and information, including storage summary, cost efficiency, data protection, and activity.

Amazon S3 Storage Lens can be used to collect storage metrics and usage data for all accounts that are part of your AWS Organizations hierarchy. To do this, you must be using AWS Organizations, and you must enable S3 Storage Lens trusted access by using your AWS Organizations management account.

When trusted access is enabled, you can add delegate administrator access to accounts in your organization. These accounts can then create organization-wide dashboards and configurations for S3 Storage Lens. For more information about enabling trusted access, see [Amazon S3 Lens and AWS Organizations](#) in the *AWS Organizations User Guide*.

The following console controls are available only to the AWS Organizations management accounts.

Enabling trusted access for S3 Storage Lens in your organization

Enabling trusted access allows Amazon S3 Storage Lens to access your AWS Organizations hierarchy, membership, and structure through AWS Organizations API operations. S3 Storage Lens becomes a trusted service for your entire organization's structure. It can create service-linked roles in your organization's management or delegated administrator accounts whenever a dashboard configuration is created.

The service-linked role grants S3 Storage Lens permissions to describe organizations, list accounts, verify a list of service access for the organizations, and get delegated administrators for the organization. This allows S3 Storage Lens to collect cross-account storage usage and activity metrics for dashboards within accounts in your organization.

For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).

Note

- Trusted access can be enabled only by the *management account*.
- Only the management account and delegated administrators can create S3 Storage Lens dashboards or configurations for your organization.

To enable S3 Storage Lens to have trusted access

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Organization settings**.
3. In **Organizations access**, choose **Edit**.

The **Organization access** page opens. Here you can **Enable trusted access** for S3 Storage Lens. This allows you and any other account holders that you add as delegated administrators to create dashboards for all accounts and storage in your organization.

Disabling S3 Storage Lens trusted access in your organization

Disabling trusted access will limit S3 Storage Lens to work only on an account level. Each account holder will only be able to see the benefits of S3 Storage Lens limited to the scope of their account, and not their organization. Any dashboards requiring trusted access will no longer be updated, but those dashboards will be able to query their historic data per the respective [period that data is available for queries](#).

Removing an account as a delegated administrator limits the account owner's S3 Storage Lens dashboard metrics access to work only on an account level. Any organizational dashboards that they created will no longer be updated, but they will be able to query their historic data per [the period that it is available for queries](#).

Note

- Disabling trusted access also automatically disables all organization-level dashboards because S3 Storage Lens will no longer have trusted access to the organization accounts to collect and aggregate storage metrics.

- The management and delegate administrator accounts can still see the historic data for these disabled dashboards and can query this data while it is available.

To disable trusted access for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Organization settings**.
3. In **Organizations access**, choose **Edit**.

The **Organization access** page opens. Here you can **Disable trusted access** for S3 Storage Lens.

Registering delegated administrators for S3 Storage Lens

After enabling trusted access, you can register delegate administrator access to accounts in your organization. When an account is registered as a delegate administrator, the account receives authorization to access all read-only AWS Organizations API operations. This provides visibility to the members and structures of your organization so that they can create S3 Storage Lens dashboards on your behalf.

To register delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Organization settings**.
3. In the **delegated access** section, for **Accounts**, choose **Add account**.

The **Delegated admin access** page opens. Here you can add an AWS account ID as a delegated administrator to create organization-level dashboards for all accounts and storage in your organization.

Deregistering delegated administrators for S3 Storage Lens

You can deregister delegate administrator access to accounts in your organization. When an account is deregistered as a delegated administrator, the account loses authorization to access all

read-only AWS Organizations API operations that provide visibility to the members and structures of your organization.

 **Note**

- Deregistering a delegated administrator also automatically disables all organization-level dashboards created by the delegated administrator.
- The delegate administrator accounts can still see the historic data for these disabled dashboards according to the respective period that data is available for queries.

To deregister accounts for delegated administrator access

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Organization settings**.
3. In the **Accounts with delegated access** section, choose the account ID you want to deregister, and then choose **Remove**.

Amazon S3 Storage Lens examples using the AWS CLI

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket. For more information, see [Assessing storage activity and usage with Amazon S3 Storage Lens](#).

The following examples show how you can use S3 Storage Lens with the AWS Command Line Interface.

- [Using Amazon S3 Storage Lens with AWS Organizations examples using the AWS CLI](#)

Helper files for using Amazon S3 Storage Lens

Use the following JSON files and its key inputs for your examples.

S3 Storage Lens example configuration in JSON

Example config.json

The config.json file contains the details of a S3 Storage Lens Organizations-level *advanced metrics and recommendations* configuration. To use the following example, replace the *user input placeholders* with your own information.

Note

Additional charges apply for advanced metrics and recommendations. For more information, see [advanced metrics and recommendations](#).

```
{  
  "Id": "SampleS3StorageLensConfiguration", //Use this property to identify your S3  
  Storage Lens configuration.  
  "AwsOrg": { //Use this property when enabling S3 Storage Lens for AWS Organizations.  
    "Arn": "arn:aws:organizations::123456789012:organization/o-abcdefg"  
  },  
  "AccountLevel": {  
    "ActivityMetrics": {  
      "Enabled": true  
    },  
    "AdvancedCostOptimizationMetrics": {  
      "Enabled": true

            "Prefix": "prefix-for-your-export-destination",
            "Encryption": {
                "SSE": {}
            }
        },
        "CloudWatchMetrics": {
            "Enabled": true
}
    }
}
```

```
 }  
 }
```

S3 Storage Lens example configuration with Storage Lens groups in JSON

Example config.json

The config.json file contains the details that you want to apply to your Storage Lens configuration when using Storage Lens groups. To use the example, replace the *user input placeholders* with your own information.

To attach all Storage Lens groups to your dashboard, update your Storage Lens configuration with the following syntax:

```
{  
  "Id": "ExampleS3StorageLensConfiguration",  
  "AccountLevel": {  
    "ActivityMetrics": {  
      "Enabled": true  
    },  
    "AdvancedCostOptimizationMetrics": {  
      "Enabled": true  
    },  
    "AdvancedDataProtectionMetrics": {  
      "Enabled": true  
    },  
    "BucketLevel": {  
      "ActivityMetrics": {  
        "Enabled": true  
      },  
      "StorageLensGroupLevel": {},  
      "Enabled": true  
    }  
}
```

To include only two Storage Lens groups in your Storage Lens dashboard configuration (*slg-1* and *slg-2*), use the following syntax:

```
{  
  "Id": "ExampleS3StorageLensConfiguration",  
  "AccountLevel": {  
    "ActivityMetrics": {  
      "Enabled": true  
    }  
  }  
}
```

```
},
"AdvancedCostOptimizationMetrics": {
    "Enabled":true
},
"AdvancedDataProtectionMetrics": {
    "Enabled":true
},
"BucketLevel": {
    "ActivityMetrics": {
        "Enabled":true
    },
    "StorageLensGroupLevel": {
        "SelectionCriteria": {
            "Include": [
                "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slg-1",
                "arn:aws:s3:us-east-1:44445556666:storage-lens-group/slg-2"
            ]
        },
        "Enabled": true
    }
}
```

To exclude only certain Storage Lens groups from being attached to your dashboard configuration, use the following syntax:

```
{
    "Id": "ExampleS3StorageLensConfiguration",
    "AccountLevel": {
        "ActivityMetrics": {
            "Enabled":true
        },
        "AdvancedCostOptimizationMetrics": {
            "Enabled":true
        },
        "AdvancedDataProtectionMetrics": {
            "Enabled":true
        },
        "BucketLevel": {
            "ActivityMetrics": {
                "Enabled":true
            },
            "StorageLensGroupLevel": {
                "SelectionCriteria": {
                    "Exclude": [

```

```
        "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slgroup/slgroup-1",
        "arn:aws:s3:us-east-1:444455556666:storage-lens-group/slgroup/slgroup-2"
    ],
},
".IsEnabled": true
}
```

S3 Storage Lens example tags configuration in JSON

Example tags.json

The tags.json file contains the tags that you want to apply to your S3 Storage Lens configuration. To use this example, replace the *user input placeholders* with your own information.

```
[
{
    "Key": "key1",
    "Value": "value1"
},
{
    "Key": "key2",
    "Value": "value2"
}
]
```

S3 Storage Lens example configuration IAM permissions

Example permissions.json – Specific dashboard name

This example policy shows an S3 Storage Lens IAM permissions.json file with a specific dashboard name specified. Replace *value1*, *us-east-1*, *your-dashboard-name*, and *example-account-id* with your own values.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetStorageLensConfiguration",
                "s3:ListStorageLensConfigurations"
            ],
            "Resource": [
                "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slgroup/slgroup-1",
                "arn:aws:s3:us-east-1:444455556666:storage-lens-group/slgroup/slgroup-2"
            ]
        }
    ]
}
```

```
        "s3>DeleteStorageLensConfiguration",
        "s3>PutStorageLensConfiguration"
    ],
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/key1": "value1"
        }
    },
    "Resource": "arn:aws:s3:us-east-1:example-account-id:storage-lens/your-dashboard-name"
}
]
```

Example permissions.json – No specific dashboard name

This example policy shows an S3 Storage Lens IAM permissions.json file without a specific dashboard name specified. Replace *value1*, *us-east-1*, and *example-account-id* with your own values.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetStorageLensConfiguration",
                "s3>DeleteStorageLensConfiguration",
                "s3>PutStorageLensConfiguration"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/key1": "value1"
                }
            },
            "Resource": "arn:aws:s3:us-east-1:example-account-id:storage-lens/*"
        }
    ]
}
```

Using Amazon S3 Storage Lens configurations with the AWS CLI

You can use the AWS CLI to list, create, delete, get, tag, and update your S3 Storage Lens configurations. The following examples use the helper JSON files for key inputs. To use these examples, replace the *user input placeholders* with your own information.

Create an S3 Storage Lens configuration

Example Create an S3 Storage Lens configuration

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-configuration=file://./config.json --tags=file://./tags.json
```

Create an S3 Storage Lens configuration without tags

Example Create an S3 Storage Lens configuration without tags

```
aws s3control put-storage-lens-configuration --account-id=222222222222 --config-id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./config.json
```

Get an S3 Storage Lens configuration

Example Get an S3 Storage Lens configuration

```
aws s3control get-storage-lens-configuration --account-id=222222222222 --config-id=your-configuration-id --region=us-east-1
```

List S3 Storage Lens configurations without a next token

Example List S3 Storage Lens configurations without a next token

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1
```

List S3 Storage Lens configurations

Example List S3 Storage Lens configurations

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1 --next-token=abcdefghijkl1234
```

Delete an S3 Storage Lens configuration

Example Delete an S3 Storage Lens configuration

```
aws s3control delete-storage-lens-configuration --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id
```

Add tags to an S3 Storage Lens configuration

Example Add tags to an S3 Storage Lens configuration

```
aws s3control put-storage-lens-configuration-tagging --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Get tags for an S3 Storage Lens configuration

Example Get tags for an S3 Storage Lens configuration

```
aws s3control get-storage-lens-configuration-tagging --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id
```

Delete tags for an S3 Storage Lens configuration

Example Delete tags for an S3 Storage Lens configuration

```
aws s3control delete-storage-lens-configuration-tagging --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id
```

Using Amazon S3 Storage Lens with AWS Organizations examples using the AWS CLI

Use Amazon S3 Storage Lens to collect storage metrics and usage data for all accounts that are part of your AWS Organizations hierarchy. For more information, see [Using Amazon S3 Storage Lens with AWS Organizations](#).

Enable Organizations trusted access for S3 Storage Lens

Example Enable Organizations trusted access for S3 Storage Lens

```
aws organizations enable-aws-service-access --service-principal storage-lens.s3.amazonaws.com
```

Disable Organizations trusted access for S3 Storage Lens

Example Disable Organizations trusted access for S3 Storage Lens

```
aws organizations disable-aws-service-access --service-principal storage-lens.s3.amazonaws.com
```

Register Organizations delegated administrators for S3 Storage Lens

Example Register Organizations delegated administrators for S3 Storage Lens

To use this example, replace **111122223333** with the appropriate AWS account ID.

```
aws organizations register-delegated-administrator --service-principal storage-lens.s3.amazonaws.com --account-id 111122223333
```

Deregister Organizations delegated administrators for S3 Storage Lens

Example Deregister Organizations delegated administrators for S3 Storage Lens

To use this example, replace **111122223333** with the appropriate AWS account ID.

```
aws organizations deregister-delegated-administrator --service-principal storage-lens.s3.amazonaws.com --account-id 111122223333
```

Amazon S3 Storage Lens examples using the SDK for Java

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket. For more information, see [Assessing storage activity and usage with Amazon S3 Storage Lens](#).

The following examples show how you can use S3 Storage Lens with the AWS SDK for Java.

Delete an S3 Storage Lens configuration

Example Delete an S3 Storage Lens configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;
```

```
public class DeleteDashboard {  
  
    public static void main(String[] args) {  
        String configurationId = "ConfigurationId";  
        String sourceAccountId = "Source Account ID";  
        try {  
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()  
                .withCredentials(new ProfileCredentialsProvider())  
                .withRegion(US_WEST_2)  
                .build();  
  
            s3ControlClient.deleteStorageLensConfiguration(new  
DeleteStorageLensConfigurationRequest()  
                .withAccountId(sourceAccountId)  
                .withConfigId(configurationId)  
            );  
        } catch (AmazonServiceException e) {  
            // The call was transmitted successfully, but Amazon S3 couldn't process  
            // it and returned an error response.  
            e.printStackTrace();  
        } catch (SdkClientException e) {  
            // Amazon S3 couldn't be contacted for a response, or the client  
            // couldn't parse the response from Amazon S3.  
            e.printStackTrace();  
        }  
    }  
}
```

Get an S3 Storage Lens configuration

Example Get an S3 Storage Lens configuration

```
package aws.example.s3control;

Attach a Storage Lens group to an S3 Storage Lens dashboard

Example Attach all Storage Lens groups to a dashboard

The following SDK for Java example attaches all Storage Lens groups in the account **111122223333** to the **DashboardConfigurationId** dashboard:

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import com.amazonaws.services.s3control.AWSS3Control;  
import com.amazonaws.services.s3control.AWS3ControlClient;  
import com.amazonaws.services.s3control.model.BucketLevel;  
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;  
import com.amazonaws.auth.profile.ProfileCredentialsProvider;  
import com.amazonaws.services.s3control.model.AccountLevel;  
import com.amazonaws.services.s3control.model.StorageLensConfiguration;  
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;  
  
import static com.amazonaws.regions.Regions.US_WEST_2;
```

```
public class CreateDashboardWithStorageLensGroups {  
    public static void main(String[] args) {  
        String configurationId = "ExampleDashboardConfigurationId";  
        String sourceAccountId = "111122223333";  
  
        try {  
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel();  
  
            AccountLevel accountLevel = new AccountLevel()  
                .withBucketLevel(new BucketLevel())  
                .withStorageLensGroupLevel(storageLensGroupLevel);  
  
            StorageLensConfiguration configuration = new StorageLensConfiguration()  
                .withId(configurationId)  
                .withAccountLevel(accountLevel)  
                .withIsEnabled(true);  
  
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()  
                .withCredentials(new ProfileCredentialsProvider())  
                .withRegion(US_WEST_2)  
                .build();  
  
            s3ControlClient.putStorageLensConfiguration(new  
PutStorageLensConfigurationRequest()  
                .withAccountId(sourceAccountId)  
                .withConfigId(configurationId)  
                .withStorageLensConfiguration(configuration)  
            );  
        } catch (AmazonServiceException e) {  
            // The call was transmitted successfully, but Amazon S3 couldn't process  
            // it and returned an error response.  
            e.printStackTrace();  
        } catch (SdkClientException e) {  
            // Amazon S3 couldn't be contacted for a response, or the client  
            // couldn't parse the response from Amazon S3.  
            e.printStackTrace();  
        }  
    }  
}
```

Example Attach two Storage Lens groups to a dashboard

The following AWS SDK for Java example attaches two Storage Lens groups (*StorageLensGroupName1* and *StorageLensGroupName2*) to the *ExampleDashboardConfigurationId* dashboard.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWith2StorageLensGroups {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String storageLensGroupName1 = "StorageLensGroupName1";
        String storageLensGroupName2 = "StorageLensGroupName2";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new
            StorageLensGroupLevelSelectionCriteria()
                .withInclude(
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName1,
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName2);

            System.out.println(selectionCriteria);
            StorageLensGroupLevel storageLensLevel = new StorageLensGroupLevel()
                .withSelectionCriteria(selectionCriteria);

            AccountLevel accountLevel = new AccountLevel()

```

```
.withBucketLevel(new BucketLevel())
.withStorageLensGroupLevel(storageLensGroupLevel);

StorageLensConfiguration configuration = new StorageLensConfiguration()
.withId(configurationId)
.withAccountLevel(accountLevel)
.withIsEnabled(true);

AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
.withCredentials(new ProfileCredentialsProvider())
.withRegion(US_WEST_2)
.build();

s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
.withAccountId(sourceAccountId)
.withConfigId(configurationId)
.withStorageLensConfiguration(configuration)
);
} catch (AmazonServiceException e) {
// The call was transmitted successfully, but Amazon S3 couldn't process
// it and returned an error response.
e.printStackTrace();
} catch (SdkClientException e) {
// Amazon S3 couldn't be contacted for a response, or the client
// couldn't parse the response from Amazon S3.
e.printStackTrace();
}
}
```

Example Attach all Storage Lens groups with exclusions

The following SDK for Java example attaches all Storage Lens groups to the *ExampleDashboardConfigurationId* dashboard, excluding the two specified (*StorageLensGroupName1* and *StorageLensGroupName2*):

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
```

```
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWith2StorageLensGroupsExcluded {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String storageLensGroupName1 = "StorageLensGroupName1";
        String storageLensGroupName2 = "StorageLensGroupName2";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new
StorageLensGroupLevelSelectionCriteria()
                .withInclude(
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName1,
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName2);

            System.out.println(selectionCriteria);
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel()
                .withSelectionCriteria(selectionCriteria);

            AccountLevel accountLevel = new AccountLevel()
                .withBucketLevel(new BucketLevel())
                .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                .withId(configurationId)
                .withAccountLevel(accountLevel)
                .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();
        }
    }
}
```

```
s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)
    .withStorageLensConfiguration(configuration)
);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Using Amazon S3 Storage Lens with AWS Organizations examples using the SDK for Java

Use Amazon S3 Storage Lens to collect storage metrics and usage data for all accounts that are part of your AWS Organizations hierarchy. For more information, see [Using Amazon S3 Storage Lens with AWS Organizations](#).

Enable Organizations trusted access for S3 Storage Lens

Example Enable Organizations trusted access for S3 Storage Lens

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
```

```
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import com.amazonaws.services.organizations.model.EnableAWSServiceAccessRequest;

public class EnableOrganizationsTrustedAccess {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.enableAWSServiceAccess(new
EnableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
    }
}
```

Disable Organizations trusted access for S3 Storage Lens

Example Disable Organizations trusted access for S3 Storage Lens

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import com.amazonaws.services.organizations.model.DisableAWSServiceAccessRequest;

public class DisableOrganizationsTrustedAccess {
```

```
private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-lens.s3.amazonaws.com";

public static void main(String[] args) {
    try {
        AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
            .withCredentials(new ProfileCredentialsProvider())
            .withRegion(Regions.US_EAST_1)
            .build();

        // Make sure to remove any existing delegated administrator for S3 Storage
        // before disabling access; otherwise, the request will fail.
        organizationsClient.disableAWSServiceAccess(new
DisableAWSServiceAccessRequest()
            .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but AWS Organizations couldn't
        // process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // AWS Organizations couldn't be contacted for a response, or the client
        // couldn't parse the response from AWS Organizations.
        e.printStackTrace();
    }
}
```

Register Organizations delegated administrators for S3 Storage Lens

Example Register Organizations delegated administrators for S3 Storage Lens

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
com.amazonaws.services.organizations.model.RegisterDelegatedAdministratorRequest;

public class RegisterOrganizationsDelegatedAdministrator {
```

```
private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-lens.s3.amazonaws.com";

public static void main(String[] args) {
    try {
        String delegatedAdminAccountId = "111122223333"; // Account Id for the
delegated administrator.
        AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
            .withCredentials(new ProfileCredentialsProvider())
            .withRegion(Regions.US_EAST_1)
            .build();

        organizationsClient.registerDelegatedAdministrator(new
RegisterDelegatedAdministratorRequest()
            .withAccountId(delegatedAdminAccountId)
            .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but AWS Organizations couldn't
process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // AWS Organizations couldn't be contacted for a response, or the client
        // couldn't parse the response from AWS Organizations.
        e.printStackTrace();
    }
}
}
```

Deregister Organizations delegated administrators for S3 Storage Lens

Example Deregister Organizations delegated administrators for S3 Storage Lens

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
com.amazonaws.services.organizations.model.DeregisterDelegatedAdministratorRequest;

public class DeregisterOrganizationsDelegatedAdministrator {
```

```
private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

public static void main(String[] args) {
    try {
        String delegatedAdminAccountId = "111122223333"; // Account Id for the
delegated administrator.

        AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
            .withCredentials(new ProfileCredentialsProvider())
            .withRegion(Regions.US_EAST_1)
            .build();

        organizationsClient.deregisterDelegatedAdministrator(new
DeregisterDelegatedAdministratorRequest()
            .withAccountId(delegatedAdminAccountId)
            .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but AWS Organizations couldn't
process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // AWS Organizations couldn't be contacted for a response, or the client
        // couldn't parse the response from AWS Organizations.
        e.printStackTrace();
    }
}
}
```

Working with S3 Storage Lens groups

An Amazon S3 Storage Lens group aggregates metrics using custom filters based on object metadata. Storage Lens groups help you drill down into characteristics of your data, such as distribution of objects by age, your most common file types, and more. For example, you can filter metrics by object tag to identify your fastest-growing datasets, or visualize your storage based on object size and age to inform your storage archive strategy. As a result, Amazon S3 Storage Lens groups helps you to better understand and optimize your S3 storage.

When you use Storage Lens groups, you can analyze and filter S3 Storage Lens metrics using object metadata such as prefixes, suffixes, [object tags](#), object size, or object age. You can also apply a combination of these filters. After you attach your Storage Lens group to your S3 Storage Lens

dashboard, you can view S3 Storage Lens metrics aggregated by Amazon S3 Storage Lens groups directly in your dashboard.

For example, you can also filter your metrics by object size or age bands to determine which portion of your storage consists of small objects. You can then use this information with S3 Intelligent-Tiering or S3 Lifecycle to transition small objects to different storage classes for cost and storage optimization.

Topics

- [How S3 Storage Lens groups work](#)
- [Using Storage Lens groups](#)

How S3 Storage Lens groups work

You can use Storage Lens groups to aggregate metrics using custom filters based on object metadata. When you define a custom filter, you can use prefixes, suffixes, object tags, object sizes, object age, or a combination of these custom filters. During Storage Lens group creation, you can also include a single filter or multiple filter conditions. To specify multiple filter conditions, you use And or Or logical operators.

When you create and configure a Storage Lens group, the Storage Lens group itself acts as a custom filter in the dashboard that you attach the group to. In your dashboard, you can then use the Storage Lens group filter to obtain storage metrics based on the custom filter that you defined in the group.

To view the data for your Storage Lens group in your S3 Storage Lens dashboard, you must attach the group to the dashboard after you've created the group. After your Storage Lens group is attached to your Storage Lens dashboard, your dashboard will collect storage usage metrics within 48 hours. You can then visualize this data in the Storage Lens dashboard or export it through a metrics export. If you forget to attach a Storage Lens group to a dashboard, your Storage Lens group data won't be captured or displayed anywhere.

Note

- When you create a S3 Storage Lens group, you're creating an AWS resource. Therefore, each Storage Lens group has its own Amazon Resource Name (ARN), which you can specify when [attaching it to or excluding it from a S3 Storage Lens dashboard](#).

- If your Storage Lens group isn't attached to a dashboard, you won't incur any additional charges for creating a Storage Lens group.
- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.

You can create a Storage Lens group at the account level in a specified home Region (from the list of supported AWS Regions). Then, you can attach your Storage Lens group to multiple Storage Lens dashboards, as long as the dashboards are in the same AWS account and home Region. You can create up to 50 Storage Lens groups per home Region in each AWS account.

You can create and manage S3 Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 REST API.

Topics

- [Viewing Storage Lens group aggregated metrics](#)
- [Storage Lens groups permissions](#)
- [Storage Lens groups configuration](#)
- [AWS resource tags](#)
- [Storage Lens groups metrics export](#)

Viewing Storage Lens group aggregated metrics

You can view the aggregated metrics for your Storage Lens groups by attaching the groups to a dashboard. The Storage Lens groups that you want to attach must reside within the designated home Region in the dashboard account.

To attach a Storage Lens group to a dashboard, you must specify the group in the **Storage Lens group aggregation** section of your dashboard configuration. If you have several Storage Lens groups, you can filter the **Storage Lens group aggregation** results to include or exclude only the groups that you want. For more information about attaching groups to your dashboards, see [the section called "Attach or remove a Storage Lens group"](#).

After you've attached your groups, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

Note

To view aggregated metrics for your Storage Lens group, you must attach the group to an S3 Storage Lens dashboard.

Storage Lens groups permissions

Storage Lens groups require certain permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens group actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to create or delete Storage Lens groups, view their configurations, or manage their tags.

The IAM user or role that you grant permissions to must belong to the account that created or owns the Storage Lens group.

To use Storage Lens groups and to view your Storage Lens groups metrics, you must first have the appropriate permissions to use S3 Storage Lens. For more information, see [the section called “S3 Storage Lens permissions”](#).

To create and manage S3 Storage Lens groups, you must have the following IAM permissions, depending on which actions you want to perform:

Action	IAM permissions
Create a new Storage Lens group	s3:CreateStorageLensGroup
Create a new Storage Lens group with tags	s3:CreateStorageLensGroup , s3:TagResource
Update an existing Storage Lens group	s3:UpdateStorageLensGroup
Return the details of a Storage Lens group configuration	s3:GetStorageLensGroup
List all Storage Lens groups in your home Region	s3>ListStorageLensGroups
Delete a Storage Lens group	s3:DeleteStorageLensGroup

Action	IAM permissions
List the tags that were added to your Storage Lens group	s3>ListTagsForResource
Add or update a Storage Lens group tag for an existing Storage Lens group	s3:TagResource
Delete a tag from a Storage Lens group	s3:UntagResource

Here's an example of how to configure your IAM policy in the account that creates the Storage Lens group. To use this policy, replace *us-east-1* with the home Region that your Storage Lens group is located in. Replace *111122223333* with your AWS account ID, and replace *example-storage-lens-group* with the name of your Storage Lens group. To apply these permissions to all Storage Lens groups, replace *example-storage-lens-group* with an *.

```

      "Action": [
        "s3>CreateStorageLensGroup",
        "s3:UpdateStorageLensGroup",
        "s3:GetStorageLensGroup",
        "s3>ListStorageLensGroups",
        "s3>DeleteStorageLensGroup",
        "s3:TagResource",
        "s3:UntagResource",
        "s3>ListTagsForResource"
      ],
      "Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens-group/example-storage-lens-group"
    }
  ]
}
```

For more information about S3 Storage Lens permissions, see [Amazon S3 Storage Lens permissions](#). For more information about IAM policy language, see [Policies and Permissions in Amazon S3](#).

Storage Lens groups configuration

S3 Storage Lens group name

We recommend giving your Storage Lens groups names that indicate their purpose so that you can easily determine which groups you want to attach to your dashboards. To [attach a Storage Lens group to a dashboard](#), you must specify the group in the **Storage Lens group aggregation** section of the dashboard configuration.

Storage Lens group names must be unique within the account. They must not exceed 64 characters, and can contain only letters (a-z, A-Z), numbers (0-9), hyphens (-), and underscores (_).

Home Region

The home Region is the AWS Region where your Storage Lens group is created and maintained. Your Storage Lens group is created in the same home Region as your Amazon S3 Storage Lens dashboard. The Storage Lens group configuration and metrics are also stored in this Region. You can create up to 50 Storage Lens groups in a home Region.

After you create your Storage Lens group, you can't edit the home Region.

Scope

To include objects in your Storage Lens group, they must be in scope for your Amazon S3 Storage Lens dashboard. The scope of your Storage Lens dashboard is determined by the buckets that you included in the **Dashboard scope** of your S3 Storage Lens dashboard configuration.

You can use different filters for your objects to define the scope of your Storage Lens group. To view these Storage Lens group metrics in your S3 Storage Lens dashboard, objects must match the filters that you include in your Storage Lens groups. For example, suppose that your Storage Lens group includes objects with the prefix marketing and the suffix .png, but no objects match those criteria. In this case, metrics for this Storage Lens group won't be generated in your daily metrics export, and no metrics for this group will be visible in your dashboard.

Filters

You can use the following filters in an S3 Storage Lens group:

- **Prefixes** – Specifies the [prefix](#) of included objects, which is a string of characters at the beginning of the object key name. For example, a value of `images` for the **Prefixes** filter includes objects with any of the following prefixes: `images/`, `images-marketing`, and `images/production`. The maximum length of a prefix is 1,024 bytes.
- **Suffixes** – Specifies the suffix of included objects (for example, `.png`, `.jpeg`, or `.csv`). The maximum length of a suffix is 1,024 bytes.
- **Object tags** – Specifies the list of [object tags](#) that you want to filter on. A tag key can't exceed 128 Unicode characters, and a tag value can't exceed 256 Unicode characters.
- **Age** – Specifies the object age range of included objects in days. Only integers are supported.
- **Size** – Specifies the object size range of included objects in bytes. Only integers are supported. The maximum allowable value is 5 TB.

Storage Lens group object tags

You can [create a Storage Lens group](#) that includes up to 10 object tag filters. The following example includes two object tag key-value pairs as filters for a Storage Lens group that's named *Marketing-Department*. To use this example, replace *Marketing-Department* with the name of your group, and replace *object-tag-key-1*, *object-tag-value-1*, and so on with the object tag key-value pairs that you want to filter on.

```
{  
    "Name": "Marketing-Department",  
    "Filter": {  
        "MatchAnyTag": [  
            {  
                "Key": "object-tag-key-1",  
                "Value": "object-tag-value-1"  
            },  
            {  
                "Key": "object-tag-key-2",  
                "Value": "object-tag-value-2"  
            }  
        ]  
    }  
}
```

Logical operators (And or Or)

To include multiple filter conditions in your Storage Lens group, you can use logical operators (either And or Or). In the following example, the Storage Lens group that's named *Marketing-Department* has an And operator that contains Prefix, ObjectAge, and ObjectSize filters. Because an And operator is used, only objects that match **all** of these filter conditions will be included the Storage Lens group's scope.

To use this example, replace the *user input placeholders* with the values that you want to filter on.

```
{  
    "Name": "Marketing-Department",  
    "Filter": {  
        "And": {  
            "MatchAnyPrefix": [  
                "prefix-1",  
                "prefix-2",  
                "prefix-3/sub-prefix-1"  
            ],  
            "MatchObjectAge": {  
                "DaysGreaterThanOrEqual": 10,  
                "DaysLessThanOrEqual": 60  
            },  
            "MatchObjectSize": {  
                "BytesGreaterThanOrEqual": 10,  
                "BytesLessThanOrEqual": 60  
            }  
        }  
    }  
}
```

Note

If you want to include objects that match **any** of the conditions in the filters, replace the And logical operator with the Or logical operator in this example.

AWS resource tags

Each S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (or tags with tag keys that begin with `aws :)`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

Storage Lens groups metrics export

S3 Storage Lens group metrics are included in the [Amazon S3 Storage Lens metrics export](#) for the dashboard that the Storage Lens group is attached to. For general information about the Storage Lens metrics export feature, see [Viewing Amazon S3 Storage Lens metrics using a data export](#).

Your metrics export for Storage Lens groups includes any S3 Storage Lens metrics that are in scope for the dashboard that you attached the Storage Lens group to. The export also includes additional metrics data for Storage Lens groups.

After you create your Storage Lens group, your metrics export is sent daily to the bucket that you selected when you configured the metrics export for the dashboard that your group is attached to. It can take up to 48 hours for you to receive the first metrics export.

To generate metrics in the daily export, objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you included in your Storage Lens group, then no metrics will be generated. However, if an object matches two or more Storage Lens groups, the object is listed separately for each group when it appears in the metrics export.

You can identify metrics for Storage Lens groups by looking for one of the following values in the `record_type` column of the metrics export for your dashboard:

- `STORAGE_LENS_GROUP_BUCKET`
- `STORAGE_LENS_GROUP_ACCOUNT`

The `record_value` column displays the resource ARN for the Storage Lens group (for example, `arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department`).

Using Storage Lens groups

Amazon S3 Storage Lens groups aggregates metrics using custom filters based on object metadata. You can analyze and filter S3 Storage Lens metrics using prefixes, suffixes, object tags, object size, or object age. With Amazon S3 Storage Lens groups, you can also categorize your usage within and across Amazon S3 buckets. As a result, you'll be able to better understand and optimize your S3 storage.

To start visualizing the data for a Storage Lens group, you must first [attach your Storage Lens group to an S3 Storage Lens dashboard](#). If you need to manage Storage Lens groups in the dashboard, you can edit the dashboard configuration. To check which Storage Lens groups are under your account, you can list them. To check which Storage Lens groups are attached to your dashboard, you can always check the **Storage Lens groups** tab in the dashboard. To review or update the scope of an existing Storage Lens group, you can view its details. You can also permanently delete a Storage Lens group.

To manage permissions, you can create and add user-defined AWS resource tags to your Storage Lens groups. You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

Creating a Storage Lens group

The following examples demonstrate how to create an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To create a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Choose **Create Storage Lens group**.
4. Under **General**, enter your Storage Lens group name and home Region.

5. Under **Scope**, choose the filter that you want to apply to your Storage Lens group. To apply multiple filters, choose your filters, and then choose the **AND** or **OR** logical operator.
 - For the **Prefixes** filter, choose **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
 - For the **Object tags** filter, choose **Object tags**, and enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
 - For the **Suffixes** filter, choose **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
 - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. Then, choose **Specify maximum object age**, and enter the maximum object age.
 - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. Choose **Specify maximum object size**, and enter the maximum object size.
6. (Optional) For AWS resource tags, add the key-value pair, and then choose **Add tag**.
7. Choose **Create Storage Lens group**.

Using the AWS CLI

The following example AWS CLI command creates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

The following example AWS CLI command creates a Storage Lens group with two AWS resource tags. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --storage-lens-group=file://./marketing-department.json \  
--tags Key=k1,Value=v1 Key=k2,Value=v2
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Using the AWS SDK for Java

The following AWS SDK for Java example creates a Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

Example – Create a Storage Lens group with a single filter

The following example creates a Storage Lens group named *Marketing-Department*. This group has an object age filter that specifies the age range as *30* to *90* days. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithObjectAge {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupFilter objectAgeFilter = StorageLensGroupFilter.builder()
                .matchObjectAge(MatchObjectAge.builder()
                    .daysGreaterThanOrEqualTo(30)
                    .daysLessThanOrEqualTo(90)
                    .build())
                .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                .name(storageLensGroupName)
                .filter(objectAgeFilter)
                .build();
        }
    }
}
```

```
        CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
    .storageLensGroup(storageLensGroup)
    .accountId(accountId).build();

    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Example – Create a Storage Lens group with an AND operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses the AND operator to indicate that objects must match **all** of the filter conditions. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.S3Tag;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupAndOperator;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
```

```
public class CreateStorageLensGroupWithAndFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create object tags.
            S3Tag tag1 = S3Tag.builder()
                .key("object-tag-key-1")
                .value("object-tag-value-1")
                .build();
            S3Tag tag2 = S3Tag.builder()
                .key("object-tag-key-2")
                .value("object-tag-value-2")
                .build();

            StorageLensGroupAndOperator andOperator =
            StorageLensGroupAndOperator.builder()
                .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                .matchAnySuffix(".png", ".gif", ".jpg")
                .matchAnyTag(tag1, tag2)
                .matchObjectAge(MatchObjectAge.builder()
                    .daysGreater Than(30)
                    .daysLessThan(90).build())
                .matchObjectSize(MatchObjectSize.builder()
                    .bytesGreater Than(1000L)
                    .bytesLessThan(6000L).build())
                .build();

            StorageLensGroupFilter andFilter = StorageLensGroupFilter.builder()
                .and(andOperator)
                .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                .name(storageLensGroupName)
                .filter(andFilter)
                .build();

            CreateStorageLensGroupRequest createStorageLensGroupRequest =
            CreateStorageLensGroupRequest.builder()
                .storageLensGroup(storageLensGroup)
                .accountId(accountId).build();
        }
    }
}
```

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(ProfileCredentialsProvider.create())
    .build();
s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Example – Create a Storage Lens group with an OR operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses an OR operator to apply a prefix filter (*prefix-1*, *prefix-2*, *prefix3*/*sub-prefix-1*) or an object size filter with a size range between *1000* bytes and *6000* bytes. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupOrOperator;

public class CreateStorageLensGroupWithOrFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
```

```
        StorageLensGroupOrOperator orOperator =
StorageLensGroupOrOperator.builder()
    .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
    .matchObjectSize(MatchObjectSize.builder()
        .bytesGreaterThanOrEqualTo(1000L)
        .bytesLessThan(6000L)
        .build())
    .build();

    StorageLensGroupFilter orFilter = StorageLensGroupFilter.builder()
        .or(orOperator)
        .build();

    StorageLensGroup storageLensGroup = StorageLensGroup.builder()
        .name(storageGroupName)
        .filter(orFilter)
        .build();

    CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
    .storageLensGroup(storageLensGroup)
    .accountId(accountId).build();

    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Example – Create a Storage Lens group with a single filter and two AWS resource tags

The following example creates a Storage Lens group named *Marketing-Department* that has a suffix filter. This example also adds two AWS resource tags to the Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.Tag;

public class CreateStorageLensGroupWithResourceTags {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create AWS resource tags.
            Tag resourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-value-1")
                .build();
            Tag resourceTag2 = Tag.builder()
                .key("resource-tag-key-2")
                .value("resource-tag-value-2")
                .build();

            StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()
                .matchAnySuffix(".png", ".gif", ".jpg")
                .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                .name(storageLensGroupName)
                .filter(suffixFilter)
                .build();
        }
    }
}
```

```
        CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
    .storageLensGroup(storageLensGroup)
    .tags(resourceTag1, resourceTag2)
    .accountId(accountId).build();

        S3ControlClient s3ControlClient = S3ControlClient.builder()
            .region(Region.US_WEST_2)
            .credentialsProvider(ProfileCredentialsProvider.create())
            .build();
        s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
}
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Attaching or removing S3 Storage Lens groups to or from your dashboard

After you've upgraded to the advanced tier in Amazon S3 Storage Lens, you can attach a [Storage Lens group](#) to your dashboard. If you have several Storage Lens groups, you can include or exclude the groups that you want.

Your Storage Lens groups must reside within the designated home Region in the dashboard account. After you attach a Storage Lens group to your dashboard, you'll receive the additional Storage Lens group aggregation data in your metrics export within 48 hours.

Note

If you want to view aggregated metrics for your Storage Lens group, you must attach it to your Storage Lens dashboard. For examples of Storage Lens group JSON configuration files, see [S3 Storage Lens example configuration with Storage Lens groups in JSON](#).

Attaching a Storage Lens group to an S3 Storage Lens dashboard

To attach a Storage Lens group to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to attach a Storage Lens group to.
4. Choose **Edit**.
5. Under **Metrics selection**, choose **Advanced metrics and recommendations**.
6. Select **Storage Lens group aggregation**.

 **Note**

By default, **Advanced metrics** is also selected. However, you can also deselect this setting as it's not required to aggregate Storage Lens groups data.

7. Scroll down to **Storage Lens group aggregation** and specify the Storage Lens group or groups that you either want to include or exclude in the data aggregation. You can use the following filtering options:
 - If you want to include certain Storage Lens groups, choose **Include Storage Lens groups**. Under **Storage Lens groups to include**, select your Storage Lens groups.
 - If you want to include all Storage Lens groups, select **Include all Storage Lens groups in home Region in this account**.
 - If you want to exclude certain Storage Lens groups, choose **Exclude Storage Lens groups**. Under **Storage Lens groups to exclude**, select the Storage Lens groups that you want to exclude.
8. Choose **Save changes**. If you've configured your Storage Lens groups correctly, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

Removing a Storage Lens group from an S3 Storage Lens dashboard

To remove a Storage Lens group from an S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to remove a Storage Lens group from.
4. Choose **View dashboard configuration**.
5. Choose **Edit**.
6. Scroll down to the **Metrics selection** section.
7. Under **Storage Lens group aggregation**, choose the **X** next to the Storage Lens group that you want to remove. This removes your Storage Lens group.

If you included all of your Storage Lens groups in your dashboard, clear the check box next to **Include all Storage Lens groups in home Region in this account**.

8. Choose **Save changes**.

 **Note**

It will take up to 48 hours for your dashboard to reflect the configuration updates.

Visualizing your Storage Lens groups data

You can visualize your Storage Lens groups data by [attaching the group to your Amazon S3 Storage Lens dashboard](#). After you've included the Storage Lens group in the Storage Lens group aggregation in your dashboard configuration, it can take up to 48 hours for the Storage Lens group data to display in your dashboard.

After the dashboard configuration has been updated, any newly attached Storage Lens groups appear in the list of available resources under the **Storage Lens groups** tab. You can also further analyze storage usage in your **Overview** tab by slicing the data by another dimension. For example, you can choose one of the items listed under the **Top 3** categories and choose **Analyze by** to slice the data by another dimension. You can't apply the same dimension as the filter itself.

Note

You can't apply a Storage Lens group filter along with a prefix filter, or the reverse. You also can't further analyze a Storage Lens group by using a prefix filter.

You can use the **Storage Lens groups** tab in the Amazon S3 Storage Lens dashboard to customize the data visualization for the Storage Lens groups that are attached to your dashboard. You can either visualize the data for some Storage Lens groups that are attached to your dashboard, or all of them.

When visualizing Storage Lens group data in your S3 Storage Lens dashboard, be aware of the following:

- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.
- Objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you include in your Storage Lens group, then no metrics are generated. To determine if there are any unassigned objects, check your total object count in the dashboard at the account level and bucket level.

Updating a Storage Lens group

The following examples demonstrate how to update an Amazon S3 Storage Lens group. You can update a Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **Scope**, choose **Edit**.

5. On the **Scope** page, select the filter that you want to apply to your Storage Lens group. To apply multiple filters, select your filters, and choose the **AND** or **OR** logical operator.
 - For the **Prefixes** filter, select **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
 - For the **Object tags** filter, enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
 - For the **Suffixes** filter, select **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
 - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. For **Specify maximum object age**, enter the maximum object age.
 - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. For **Specify maximum object size**, enter the maximum object size.
6. Choose **Save changes**. The details page for the Storage Lens group appears.
7. (Optional) If you want to add a new AWS resource tag, scroll to the **AWS resource tags** section, then choose **Add tags**. The **Add tags** page appears.

Add the new key-value pair, then choose **Save changes**. The details page for the Storage Lens group appears.

8. (Optional) If you want to remove an existing AWS resource tag, scroll to the **AWS resource tags** section, and select the resource tag. Then, choose **Delete**. The **Delete AWS tags** dialog box appears.

Choose **Delete** again to permanently delete the AWS resource tag.

 **Note**

After you permanently delete an AWS resource tag, it can't be restored.

Using the AWS CLI

The following AWS CLI example command returns the configuration details for a Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

The following AWS CLI example updates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control update-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the *Marketing-Department* Storage Lens group in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;

public class GetStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            GetStorageLensGroupRequest getRequest =
GetStorageLensGroupRequest.builder()
```

```
        .name(storageLensGroupName)
        .accountId(accountId).build();
    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    GetStorageLensGroupResponse response =
s3ControlClient.getStorageLensGroup(getRequest);
    System.out.println(response);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

The following example updates the Storage Lens group named *Marketing-Department* in account *111122223333*. This example updates the dashboard scope to include objects that match any of the following suffixes: *.png*, *.gif*, *.jpg*, or *.jpeg*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;

    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Managing AWS resource tags with Storage Lens groups

Each Amazon S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with aws :) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens groups.

Adding an AWS resource tag to a Storage Lens group

The following examples demonstrate how to add AWS resource tags to an Amazon S3 Storage Lens group. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add an AWS resource tag to a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, choose **Add tags**.
5. On the **Add tags** page, add the new key-value pair.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens group.
7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command adds two resource tags to an existing Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
--region us-east-1 --tags Key=k1,Value=v1 Key=k2,Value=v2
```

Using the AWS SDK for Java

The following AWS SDK for Java example adds two AWS resource tags to an existing Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class TagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag resourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-value-1")
                .build();
            Tag resourceTag2 = Tag.builder()
                .key("resource-tag-key-2")
                .value("resource-tag-value-2")
                .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                .resourceArn(resourceARN)
                .tags(resourceTag1, resourceTag2)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            s3ControlClient.tagResource(tagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

```
}
```

Updating Storage Lens group tag values

The following examples demonstrate how to update Storage Lens group tag values by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the tag that you want to update.
5. Add the new tag value, using the same key of the key-value pair that you want to update. Choose the checkmark icon to update the tag value.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) If you want to add new tags, choose **Add tag** to add new entries. The **Add tags** page appears.

You can add up to 50 AWS resource tags for your Storage Lens group. When you're finished adding new tags, choose **Save changes**.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove. When you're finished removing tags, choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command updates two tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
--region us-east-1 --tags Key=k1,Value=v3 Key=k2,Value=v4
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates two Storage Lens group tag values. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class UpdateTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag updatedResourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-updated-value-1")
                .build();
            Tag updatedResourceTag2 = Tag.builder()
                .key("resource-tag-key-2")
                .value("resource-tag-updated-value-2")
                .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                .resourceArn(resourceARN)
                .tags(updatedResourceTag1, updatedResourceTag2)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
        }
    }
}
```

```
s3ControlClient.tagResource(tagResourceRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Deleting an AWS resource tag from a Storage Lens group

The following examples demonstrate how to delete an AWS resource tag from a Storage Lens group. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete an AWS resource tag from a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the key-value pair that you want to delete.
5. Choose **Delete**. The **Delete AWS resource tags** dialog box appears.

 **Note**

If tags are used to control access, proceeding with this action can affect related resources. After you permanently delete a tag, it can't be restored.

6. Choose **Delete** to permanently delete the key-value pair.

Using the AWS CLI

The following AWS CLI command deletes two AWS resource tags from an existing Storage Lens group: To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control untag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department \
--region us-east-1 --tag-keys k1 k2
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes two AWS resource tags from the Storage Lens group Amazon Resource Name (ARN) that you specify in account **111122223333**. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.UntagResourceRequest;

public class UntagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            String tagKey1 = "resource-tag-key-1";
            String tagKey2 = "resource-tag-key-2";
            UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
                .resourceArn(resourceARN)
                .tagKeys(tagKey1, tagKey2)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
        }
    }
}
```

```
        .build();
    s3ControlClient.untagResource(untagResourceRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Listing Storage Lens group tags

The following examples demonstrate how to list the AWS resource tags associated with a Storage Lens group. You can list tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To review the list of tags and tag values for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you're interested in.
4. Scroll down to the **AWS resource tags** section. All of the user-defined AWS resource tags that are added to your Storage Lens group are listed along with their tag values.

Using the AWS CLI

The following AWS CLI example command lists all the Storage Lens group tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control list-tags-for-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
```

```
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens group tag values for the Storage Lens group Amazon Resource Name (ARN) that you specify. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
                .resourceArn(resourceARN)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            ListTagsForResourceResponse response =
s3ControlClient.listTagsForResource(listTagsForResourceRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
        }
    }
}
```

```
        e.printStackTrace();
    }
}
}
```

Listing all Storage Lens groups

The following examples demonstrate how to list all Amazon S3 Storage Lens groups in an AWS account and home Region. These examples show how list all Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To list all Storage Lens groups in an account and home Region

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, the list of Storage Lens groups in your account is displayed.

Using the AWS CLI

The following AWS CLI example lists all of the Storage Lens groups for your account. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-groups --account-id 111122223333 \
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens groups for account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsRequest;
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsResponse;

public class ListStorageLensGroups {
    public static void main(String[] args) {
        String accountId = "111122223333";

        try {
            ListStorageLensGroupsRequest listStorageLensGroupsRequest =
ListStorageLensGroupsRequest.builder()
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            ListStorageLensGroupsResponse response =
s3ControlClient.listStorageLensGroups(listStorageLensGroupsRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Viewing Storage Lens group details

The following examples demonstrate how to view Amazon S3 Storage Lens group configuration details. You can view these details by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To view Storage Lens group configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you're interested in.
4. Choose **View details**. You can now review the details of your Storage Lens group.

Using the AWS CLI

The following AWS CLI example returns the configuration details for a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.s3control.S3ControlClient;  
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;  
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;  
  
public class GetStorageLensGroup {  
    public static void main(String[] args) {  
        String storageLensGroupName = "Marketing-Department";  
        String accountId = "111122223333";  
  
        try {  
            GetStorageLensGroupRequest getRequest =  
GetStorageLensGroupRequest.builder()  
                .name(storageLensGroupName)  
                .accountId(accountId).build();  
            S3ControlClient s3ControlClient = S3ControlClient.builder()
```

```
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    GetStorageLensGroupResponse response =
s3ControlClient.getStorageLensGroup(getRequest);
    System.out.println(response);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Deleting a Storage Lens group

The following examples demonstrate how to delete an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you want to delete.
4. Choose **Delete**. A **Delete Storage Lens group** dialog box displays.
5. Choose **Delete** again to permanently delete your Storage Lens group.

Note

After you delete a Storage Lens group, it can't be restored.

Using the AWS CLI

The following AWS CLI example deletes the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.s3control.S3ControlClient;  
import software.amazon.awssdk.services.s3control.model.DeleteStorageLensGroupRequest;  
  
public class DeleteStorageLensGroup {  
    public static void main(String[] args) {  
        String storageLensGroupName = "Marketing-Department";  
        String accountId = "111122223333";  
  
        try {  
            DeleteStorageLensGroupRequest deleteStorageLensGroupRequest =  
DeleteStorageLensGroupRequest.builder()  
                .name(storageLensGroupName)  
                .accountId(accountId).build();  
            S3ControlClient s3ControlClient = S3ControlClient.builder()  
                .region(Region.US_WEST_2)  
                .credentialsProvider(ProfileCredentialsProvider.create())  
                .build();  
            s3ControlClient.deleteStorageLensGroup(deleteStorageLensGroupRequest);  
        } catch (AmazonServiceException e) {  
            // The call was transmitted successfully, but Amazon S3 couldn't process  
            // it and returned an error response.  
        }  
    }  
}
```

```
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

Tracing Amazon S3 requests using AWS X-Ray

AWS X-Ray collects data about requests that your application serves. You can then view and filter the data to identify and troubleshoot performance issues and errors in your distributed applications and micro-services architecture. For any traced request to your application, it shows you detailed information about the request, the response, and the calls that your application makes to downstream AWS resources, micro-services, databases, and HTTP web APIs.

For more information, see [What is AWS X-Ray?](#) in the *AWS X-Ray Developer Guide*.

Topics

- [How X-Ray works with Amazon S3](#)
- [Available Regions](#)

How X-Ray works with Amazon S3

AWS X-Ray supports trace context propagation for Amazon S3, so you can view end-to-end requests as they travel through your entire application. X-Ray aggregates the data that is generated by the individual services such as Amazon S3, AWS Lambda, and Amazon EC2, and the many resources that make up your application. It provides you with an overall view of how your application is performing.

Amazon S3 integrates with X-Ray to propagate [trace context](#) and give you one request chain with [upstream and downstream](#) nodes. If an upstream service includes a valid-formatted trace header with its S3 request, Amazon S3 passes the trace header when delivering event notifications to downstream services such as Lambda, Amazon SQS, and Amazon SNS. If you have all these services actively integrated with X-Ray, they are linked in one request chain to give you the complete details of your Amazon S3 requests.

To send X-Ray trace headers through Amazon S3, you must include a [formatted X-Amzn-Trace-Id](#) in your requests. You can also instrument the Amazon S3 client using the AWS X-Ray SDKs. For a list of the supported SDKs, see the [AWS X-Ray documentation](#).

Service maps

X-Ray *service maps* show you the relationships between Amazon S3 and other AWS services and resources in your application in near-real time. To see the end-to-end requests using the X-Ray service maps, you can use the X-Ray console to view a map of the connections between Amazon S3 and other services that your application uses. You can easily detect where high latency is occurring, visualize node distribution for these services, and then drill down into the specific services and paths impacting application performance.

X-Ray Analytics

You can also use the [X-Ray Analytics](#) console to analyze traces, view metrics such as latency and failure rates, and [generate insights](#) to help you identify and troubleshoot issues. This console also shows you metrics such as average latency and failure rates. For more information, see [AWS X-Ray console](#) in the *AWS X-Ray Developer Guide*.

Available Regions

AWS X-Ray support for Amazon S3 is available in all [AWS X-Ray Regions](#). For more information, see [Amazon S3 and AWS X-Ray](#) in the *AWS X-Ray Developer Guide*.

Hosting a static website using Amazon S3

You can use Amazon S3 to host a static website. On a *static* website, individual webpages include static content. They might also contain client-side scripts.

By contrast, a *dynamic* website relies on server-side processing, including server-side scripts, such as PHP, JSP, or ASP.NET. Amazon S3 does not support server-side scripting, but AWS has other resources for hosting dynamic websites. To learn more about website hosting on AWS, see [Web Hosting](#).

Note

You can use the AWS Amplify Console to host a single-page web app. The AWS Amplify Console supports single-page apps built with single-page app frameworks (for example, React JS, Vue JS, Angular JS, and Nuxt) and static site generators (for example, Gatsby JS, React-static, Jekyll, and Hugo). For more information, see [Getting Started](#) in the *AWS Amplify Console User Guide*.

Amazon S3 website endpoints do not support HTTPS. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3. For more information, see [How do I use CloudFront to serve HTTPS requests for my Amazon S3 bucket?](#) To use HTTPS with a custom domain, see [Configuring a static website using a custom domain registered with Route 53](#).

For more information about hosting a static website on Amazon S3, including instructions and step-by-step walkthroughs, see the following topics.

Topics

- [Website endpoints](#)
- [Enabling website hosting](#)
- [Configuring an index document](#)
- [Configuring a custom error document](#)
- [Setting permissions for website access](#)
- [\(Optional\) Logging web traffic](#)
- [\(Optional\) Configuring a webpage redirect](#)

Website endpoints

When you configure your bucket as a static website, the website is available at the AWS Region-specific website endpoint of the bucket. Website endpoints are different from the endpoints where you send REST API requests. For more information about the differences between the endpoints, see [Key differences between a website endpoint and a REST API endpoint](#).

Depending on your Region, your Amazon S3 website endpoint follows one of these two formats.

- **s3-website dash (-) Region** - `http://bucket-name.s3-website-Region.amazonaws.com`
- **s3-website dot (.) Region** - `http://bucket-name.s3-website.Region.amazonaws.com`

These URLs return the default index document that you configure for the website. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website Endpoints](#).

Note

To augment the security of your Amazon S3 static websites, the Amazon S3 website endpoint domains (for example, `s3-website-us-east-1.amazonaws.com` or `s3-website.ap-south-1.amazonaws.com`) are registered in the [Public Suffix List \(PSL\)](#). For further security, we recommend that you use cookies with a `_Host-` prefix if you ever need to set sensitive cookies in the domain name for your Amazon S3 static websites. This practice will help to defend your domain against cross-site request forgery attempts (CSRF). For more information see the [Set-Cookie](#) page in the Mozilla Developer Network.

If you want your website to be public, you must make all your content publicly readable for your customers to be able to access it at the website endpoint. For more information, see [Setting permissions for website access](#).

Important

Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3. For more information, see [How do I use CloudFront to serve HTTPS requests for my Amazon S3 bucket?](#) To use HTTPS with a custom domain, see [Configuring a static website using a custom domain registered with Route 53](#).

Requester Pays buckets do not allow access through a website endpoint. Any request to such a bucket receives a 403 Access Denied response. For more information, see [Using Requester Pays buckets for storage transfers and usage](#).

Topics

- [Website endpoint examples](#)
- [Adding a DNS CNAME](#)
- [Using a custom domain with Route 53](#)
- [Key differences between a website endpoint and a REST API endpoint](#)

Website endpoint examples

The following examples show how you can access an Amazon S3 bucket that is configured as a static website.

Example — Requesting an object at the root level

To request a specific object that is stored at the root level in the bucket, use the following URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/object-name
```

For example, the following URL requests the photo.jpg object that is stored at the root level in the bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/photo.jpg
```

Example — Requesting an object in a prefix

To request an object that is stored in a folder in your bucket, use this URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/folder-name/object-name
```

The following URL requests the docs/doc1.html object in your bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/docs/doc1.html
```

Adding a DNS CNAME

If you have a registered domain, you can add a DNS CNAME entry to point to the Amazon S3 website endpoint. For example, if you registered the domain `www.example-bucket.com`, you could create a bucket `www.example-bucket.com`, and add a DNS CNAME record that points to `www.example-bucket.com.s3-website.Region.amazonaws.com`. All requests to `http://www.example-bucket.com` are routed to `www.example-bucket.com.s3-website.Region.amazonaws.com`.

For more information, see [Customizing Amazon S3 URLs with CNAME records](#).

Using a custom domain with Route 53

Instead of accessing the website using an Amazon S3 website endpoint, you can use your own domain registered with Amazon Route 53 to serve your content—for example, `example.com`. You can use Amazon S3 with Route 53 to host a website at the root domain. For example, if you have the root domain `example.com` and you host your website on Amazon S3, your website visitors can access the site from their browser by entering either `http://www.example.com` or `http://example.com`.

For an example walkthrough, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Key differences between a website endpoint and a REST API endpoint

An Amazon S3 website endpoint is optimized for access from a web browser. The following table summarizes the key differences between a REST API endpoint and a website endpoint.

Key difference	REST API endpoint	Website endpoint
Access control	Supports both public and private content	Supports only publicly readable content
Error message handling	Returns an XML-formatted error response	Returns an HTML document
Redirection support	Not applicable	Supports both object-level and bucket-level redirects

Key difference	REST API endpoint	Website endpoint
Requests supported	Supports all bucket and object operations	Supports only GET and HEAD requests on objects
Responses to GET and HEAD requests at the root of a bucket	Returns a list of the object keys in the bucket	Returns the index document that is specified in the website configuration
Secure Sockets Layer (SSL) support	Supports SSL connections	Does not support SSL connections

For a complete list of Amazon S3 endpoints, see [Amazon S3 endpoints and quotas](#) in the *AWS General Reference*.

Enabling website hosting

When you configure a bucket as a static website, you must enable static website hosting, configure an index document, and set permissions.

You can enable static website hosting using the Amazon S3 console, REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation.

To configure your website with a custom domain, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Using the S3 console

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to enable static website hosting for.
3. Choose **Properties**.

4. Under **Static website hosting**, choose **Edit**.
5. Choose **Use this bucket to host a website**.
6. Under **Static website hosting**, choose **Enable**.
7. In **Index document**, enter the file name of the index document, typically `index.html`.

The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see [Configuring an index document](#).

8. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see [Configuring a custom error document](#).

9. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see [Configure redirection rules to use advanced conditional redirects](#).

10. Choose **Save changes**.

Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

11. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Using the REST API

For more information about sending REST requests directly to enable static website hosting, see the following sections in the Amazon Simple Storage Service API Reference:

- [PUT Bucket website](#)
- [GET Bucket website](#)
- [DELETE Bucket website](#)

Using the AWS SDKs

To host a static website on Amazon S3, you configure an Amazon S3 bucket for website hosting and then upload your website content to the bucket. You can also use the AWS SDKs to create, update, and delete the website configuration programmatically. The SDKs provide wrapper classes around the Amazon S3 REST API. If your application requires it, you can send REST API requests directly from your application.

.NET

The following example shows how to use the AWS SDK for .NET to manage website configuration for a bucket. To add a website configuration to a bucket, you provide a bucket name and a website configuration. The website configuration must include an index document and can contain an optional error document. These documents must be stored in the bucket. For more information, see [PUT Bucket website](#). For more information about the Amazon S3 website feature, see [Hosting a static website using Amazon S3](#).

The following C# code example adds a website configuration to the specified bucket. The configuration specifies both the index document and the error document names. For instructions on how to create and test a working sample, see [Running the Amazon S3 .NET Code Examples](#).

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class WebsiteConfigTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string indexDocumentSuffix = "*** index object key ***"; // For example, index.html.
```

```
    private const string errorDocument = "*** error object key ***"; // For
example, error.html.

    // Specify your bucket region (an example region is shown).
    private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
    private static IAmazonS3 client;
    public static void Main()
{
    client = new AmazonS3Client(bucketRegion);
    AddWebsiteConfigurationAsync(bucketName, indexDocumentSuffix,
errorDocument).Wait();
}

static async Task AddWebsiteConfigurationAsync(string bucketName,
                                                string indexDocumentSuffix,
                                                string errorDocument)
{
    try
    {
        // 1. Put the website configuration.
        PutBucketWebsiteRequest putRequest = new PutBucketWebsiteRequest()
        {
            BucketName = bucketName,
            WebsiteConfiguration = new WebsiteConfiguration()
            {
                IndexDocumentSuffix = indexDocumentSuffix,
                ErrorDocument = errorDocument
            }
        };
        PutBucketWebsiteResponse response = await
client.PutBucketWebsiteAsync(putRequest);

        // 2. Get the website configuration.
        GetBucketWebsiteRequest getRequest = new GetBucketWebsiteRequest()
        {
            BucketName = bucketName
        };
        GetBucketWebsiteResponse getResponse = await
client.GetBucketWebsiteAsync(getRequest);
        Console.WriteLine("Index document: {0}",
getResponse.WebsiteConfiguration.IndexDocumentSuffix);
        Console.WriteLine("Error document: {0}",
getResponse.WebsiteConfiguration.ErrorDocument);
    }
}
```

```
        catch (AmazonS3Exception e)
        {
            Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
        }
        catch (Exception e)
        {
            Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
        }
    }
}
```

PHP

The following PHP example adds a website configuration to the specified bucket. The `create_website_config` method explicitly provides the index document and error document names. The example also retrieves the website configuration and prints the response. For more information about the Amazon S3 website feature, see [Hosting a static website using Amazon S3](#).

For instructions on creating and testing a working sample, see [Using the AWS SDK for PHP and Running PHP Examples](#).

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Add the website configuration.
$s3->putBucketWebsite([
    'Bucket'              => $bucket,
    'WebsiteConfiguration' => [
        'IndexDocument' => ['Suffix' => 'index.html'],
        'ErrorDocument'  => ['Key' => 'error.html']
    ]
]);
```

```
    ]  
]);  
  
// Retrieve the website configuration.  
$result = $s3->getBucketWebsite([  
    'Bucket' => $bucket  
]);  
echo $result->getPath('IndexDocument/Suffix');  
  
// Delete the website configuration.  
$s3->deleteBucketWebsite([  
    'Bucket' => $bucket  
]);
```

Using the AWS CLI

For more information about using the AWS CLI to configure an S3 bucket as a static website, see [website](#) in the *AWS CLI Command Reference*.

Next, you must configure your index document and set permissions. For information, see [Configuring an index document](#) and [Setting permissions for website access](#).

You can also optionally configure an [error document](#), [web traffic logging](#), or a [redirect](#).

Configuring an index document

When you enable website hosting, you must also configure and upload an index document. An *index document* is a webpage that Amazon S3 returns when a request is made to the root of a website or any subfolder. For example, if a user enters `http://www.example.com` in the browser, the user is not requesting any specific page. In that case, Amazon S3 serves up the index document, which is sometimes referred to as the *default page*.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for your bucket, you upload an HTML file with the index document name to your bucket.

The trailing slash at the root-level URL is optional. For example, if you configure your website with `index.html` as the index document, either of the following URLs returns `index.html`.

```
http://example-bucket.s3-website.Region.amazonaws.com/
```

`http://example-bucket.s3-website.Region.amazonaws.com`

For more information about Amazon S3 website endpoints, see [Website endpoints](#).

Index document and folders

In Amazon S3, a bucket is a flat container of objects. It does not provide any hierarchical organization as the file system on your computer does. However, you can create a logical hierarchy by using object key names that imply a folder structure.

For example, consider a bucket with three objects that have the following key names. Although these are stored with no physical hierarchical organization, you can infer the following logical folder structure from the key names:

- `sample1.jpg` — Object is at the root of the bucket.
- `photos/2006/Jan/sample2.jpg` — Object is in the `photos/2006/Jan` subfolder.
- `photos/2006/Feb/sample3.jpg` — Object is in the `photos/2006/Feb` subfolder.

In the Amazon S3 console, you can also create a folder in a bucket. For example, you can create a folder named `photos`. You can upload objects to the bucket or to the `photos` folder within the bucket. If you add the object `sample.jpg` to the bucket, the key name is `sample.jpg`. If you upload the object to the `photos` folder, the object key name is `photos/sample.jpg`.

If you create a folder structure in your bucket, you must have an index document at each level. In each folder, the index document must have the same name, for example, `index.html`. When a user specifies a URL that resembles a folder lookup, the presence or absence of a trailing slash determines the behavior of the website. For example, the following URL, with a trailing slash, returns the `photos/index.html` index document.

`http://bucket-name.s3-website.Region.amazonaws.com/photos/`

However, if you exclude the trailing slash from the preceding URL, Amazon S3 first looks for an object `photos` in the bucket. If the `photos` object is not found, it searches for an index document, `photos/index.html`. If that document is found, Amazon S3 returns a 302 Found message and points to the `photos/` key. For subsequent requests to `photos/`, Amazon S3 returns `photos/index.html`. If the index document is not found, Amazon S3 returns an error.

Configure an index document

To configure an index document using the S3 console, use the following procedure. You can also configure an index document using the REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation.

Note

In a versioning-enabled bucket, you may upload multiple copies of the `index.html` but only the newest version will be resolved to. For more information about using S3 Versioning see, [Using versioning in S3 buckets](#).

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

If you don't have an `index.html` file, you can use the following HTML to create one:

```
<html xmlns="http://www.w3.org/1999/xhtml" >
<head>
    <title>My Website Home Page</title>
</head>
<body>
    <h1>Welcome to my website</h1>
    <p>Now hosted on Amazon S3!</p>
</body>
</html>
```

2. Save the index file locally.

The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the **Buckets** list, choose the name of the bucket that you want to use to host a static website.
5. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see [Enabling website hosting](#).

After enabling static website hosting, proceed to step 6.

6. To upload the index document to your bucket, do one of the following:
 - Drag and drop the index file into the console bucket listing.
 - Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

7. (Optional) Upload other website content to your bucket.

Next, you must set permissions for website access. For information, see [Setting permissions for website access](#).

You can also optionally configure an [error document](#), [web traffic logging](#), or a [redirect](#).

Configuring a custom error document

After you configure your bucket as a static website, when an error occurs, Amazon S3 returns an HTML error document. You can optionally configure your bucket with a custom error document so that Amazon S3 returns that document when an error occurs.

Note

Some browsers display their own error message when an error occurs, ignoring the error document that Amazon S3 returns. For example, when an HTTP 404 Not Found error occurs, Google Chrome might ignore the error document that Amazon S3 returns and display its own error.

Topics

- [Amazon S3 HTTP response codes](#)
- [Configuring a custom error document](#)

Amazon S3 HTTP response codes

The following table lists the subset of HTTP response codes that Amazon S3 returns when an error occurs.

HTTP error code	Description
301 Moved Permanently	When a user sends a request directly to the Amazon S3 website endpoint (<code>http://s3-website. <i>Region</i>.amazonaws.com/</code>), Amazon S3 returns a 301 Moved Permanently response and redirects those requests to <code>https://aws.amazon.com/s3/</code> .
302 Found	When Amazon S3 receives a request for a key x, <code>http://<i>bucket-name</i>.s3-website. <i>Region</i>.amazonaws.com/x</code> , without a trailing slash, it first looks for the object with the key name x. If the object is not found, Amazon S3 determines that the request is for subfolder x and redirects the request by adding a slash at the end, and returns 302 Found .
304 Not Modified	Amazon S3 uses request headers <code>If-Modified-Since</code> , <code>If-Unmodified-Since</code> , <code>If-Match</code> and/or <code>If-None-Match</code> to determine whether the requested object is same as the cached copy held by the client. If the object is the same, the website endpoint returns a 304 Not Modified response.
400 Malformed Request	The website endpoint responds with a 400 Malformed Request when a user attempts to access a bucket through the incorrect regional endpoint.
403 Forbidden	The website endpoint responds with a 403 Forbidden when a user request translates to an object that is not publicly readable. The object owner must make the object publicly readable using a bucket policy or an ACL.
404 Not Found	

HTTP error code	Description
	<p>The website endpoint responds with 404 Not Found for the following reasons:</p> <ul style="list-style-type: none">• Amazon S3 determines that the URL of the website refers to an object key that does not exist.• Amazon S3 infers that the request is for an index document that does not exist.• A bucket specified in the URL does not exist.• A bucket specified in the URL exists, but isn't configured as a website. <p>You can create a custom document that is returned for 404 Not Found. Make sure that the document is uploaded to the bucket configured as a website, and that the website hosting configuration is set to use the document.</p> <p>For information on how Amazon S3 interprets the URL as a request for an object or an index document, see Configuring an index document.</p>
500 Service Error	The website endpoint responds with a 500 Service Error when an internal server error occurs.
503 Service Unavailable	The website endpoint responds with a 503 Service Unavailable when Amazon S3 determines that you need to reduce your request rate.

For each of these errors, Amazon S3 returns a predefined HTML message. The following is an example HTML message that is returned for a **403 Forbidden** response.

403 Forbidden

- Code: AccessDenied
- Message: Access Denied
- RequestId: 873CA367A51F7EC7
- HostId: DdQezl9vkuw5luD5HKsFaTDm9KH4PZzCPRkW3igimILbTu1DiYlvXjgyd7pVxq32

An Error Occurred While Attempting to Retrieve a Custom Error Document

- Code: AccessDenied
- Message: Access Denied

Configuring a custom error document

When you configure your bucket as a static website, you can provide a custom error document that contains a user-friendly error message and additional help. Amazon S3 returns your custom error document for only the HTTP 4XX class of error codes.

To configure a custom error document using the S3 console, follow the steps below. You can also configure an error document using the REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation. For more information, see the following:

- [PutBucketWebsite](#) in the *Amazon Simple Storage Service API Reference*
- [AWS::S3::Bucket WebsiteConfiguration](#) in the *AWS CloudFormation User Guide*
- [put-bucket-website](#) in the *AWS CLI Command Reference*

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **404.html**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error**

document name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the **Buckets** list, choose the name of the bucket that you want to use to host a static website.
5. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see [Enabling website hosting](#) and [Configuring a custom error document](#).

After enabling static website hosting, proceed to step 6.

6. To upload the error document to your bucket, do one of the following:
 - Drag and drop the error document file into the console bucket listing.
 - Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

Setting permissions for website access

When you configure a bucket as a static website, if you want your website to be public, you can grant public read access. To make your bucket publicly readable, you must disable block public access settings for the bucket and write a bucket policy that grants public read access. If your bucket contains objects that are not owned by the bucket owner, you might also need to add an object access control list (ACL) that grants everyone read access.

If you don't want to disable block public access settings for your bucket but you still want your website to be public, you can create a Amazon CloudFront distribution to serve your static website. For more information, see [Speeding up your website with Amazon CloudFront](#) or [Use an Amazon CloudFront distribution to serve a static website](#) in the *Amazon Route 53 Developer Guide*.

Note

On the website endpoint, if a user requests an object that doesn't exist, Amazon S3 returns HTTP response code 404 (Not Found). If the object exists but you haven't granted read permission on it, the website endpoint returns HTTP response code 403 (Access

Denied). The user can use the response code to infer whether a specific object exists. If you don't want this behavior, you should not enable website support for your bucket.

Topics

- [Step 1: Edit S3 Block Public Access settings](#)
- [Step 2: Add a bucket policy](#)
- [Object access control lists](#)

Step 1: Edit S3 Block Public Access settings

If you want to configure an existing bucket as a static website that has public access, you must edit Block Public Access settings for that bucket. You might also have to edit your account-level Block Public Access settings. Amazon S3 applies the most restrictive combination of the bucket-level and account-level block public access settings.

For example, if you allow public access for a bucket but block all public access at the account level, Amazon S3 will continue to block public access to the bucket. In this scenario, you would have to edit your bucket-level and account-level Block Public Access settings. For more information, see [Blocking public access to your Amazon S3 storage](#).

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete this step, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.

5. Clear Block *all* public access, and choose Save changes.

Warning

Before you complete this step, review [Blocking public access to your Amazon S3 storage](#) to ensure you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

Block public access (bucket settings)

Public access is granted to buckets and objects through access control lists (ACLs), bucket policies, access point policies, or all. In order to ensure that public access to all your S3 buckets and objects is blocked, turn on Block all public access. These settings apply only to this bucket and its access points. AWS recommends that you turn on Block all public access, but before applying any of these settings, ensure that your applications will work correctly without public access. If you require some level of public access to your buckets or objects within, you can customize the individual settings below to suit your specific storage use cases. [Learn more](#) 

Account settings for Block Public Access are currently turned on

Account settings for Block Public Access that are enabled apply even if they are disabled for this bucket.

Block *all* public access

Turning this setting on is the same as turning on all four settings below. Each of the following settings are independent of one another.

Block public access to buckets and objects granted through *new* access control lists (ACLs)

S3 will block public access permissions applied to newly added buckets or objects, and prevent the creation of new public access ACLs for existing buckets and objects. This setting doesn't change any existing permissions that allow public access to S3 resources using ACLs.

Block public access to buckets and objects granted through *any* access control lists (ACLs)

S3 will ignore all ACLs that grant public access to buckets and objects.

Block public access to buckets and objects granted through *new* public bucket or access point policies

S3 will block new bucket and access point policies that grant public access to buckets and objects. This setting doesn't change any existing policies that allow public access to S3 resources.

Block public and cross-account access to buckets and objects through *any* public bucket or access point policies

S3 will ignore public and cross-account access for buckets or access points with policies that grant public access to buckets and objects.

Amazon S3 turns off Block Public Access settings for your bucket. To create a public, static website, you might also have to [edit the Block Public Access settings](#) for your account before

adding a bucket policy. If account settings for Block Public Access are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 2: Add a bucket policy

To make the objects in your bucket publicly readable, you must write a bucket policy that grants everyone s3:GetObject permission.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review [How can I secure the files in my Amazon S3 bucket?](#) to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::Bucket-Name/*"  
            ]  
        }  
    ]  
}
```

```
        ]  
    }  
]  
}
```

5. Update the Resource to your bucket name.

In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see [How do I add an S3 bucket policy?](#)

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Object access control lists

You can use a bucket policy to grant public read permission to your objects. However, the bucket policy applies only to objects that are owned by the bucket owner. If your bucket contains objects that aren't owned by the bucket owner, the bucket owner should use the object access control list (ACL) to grant public READ permission on those objects.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

⚠ Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To make an object publicly readable using an ACL, grant READ permission to the `AllUsers` group, as shown in the following grant element. Add this grant element to the object ACL. For information about managing ACLs, see [Access control list \(ACL\) overview](#).

```
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
  </Grantee>
  <Permission>READ</Permission>
</Grant>
```

(Optional) Logging web traffic

You can optionally enable Amazon S3 server access logging for a bucket that is configured as a static website. Server access logging provides detailed records for the requests that are made to your bucket. For more information, see [Logging requests with server access logging](#). If you plan to use Amazon CloudFront to [speed up your website](#), you can also use CloudFront logging. For more information, see [Configuring and Using Access Logs](#) in the *Amazon CloudFront Developer Guide*.

To enable server access logging for your static website bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the same Region where you created the bucket that is configured as a static website, create a bucket for logging, for example `logs.example.com`.
3. Create a folder for the server access logging log files (for example, `logs`).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, `cdn`).

For more information, see [Speeding up your website with Amazon CloudFront](#).

5. In the **Buckets** list, choose your bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:
 - Browse to the folder and bucket location:
 1. Choose **Browse S3**.
 2. Choose the bucket name, and then choose the logs folder.
 3. Choose **Choose path**.
 - Enter the S3 bucket path, for example, `s3://logs.example.com/logs/`.
10. Choose **Save changes**.

In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

(Optional) Configuring a webpage redirect

If your Amazon S3 bucket is configured for static website hosting, you can configure redirects for your bucket or the objects in it. You have the following options for configuring redirects.

Topics

- [Redirect requests for your bucket's website endpoint to another bucket or domain](#)
- [Configure redirection rules to use advanced conditional redirects](#)
- [Redirect requests for an object](#)

Redirect requests for your bucket's website endpoint to another bucket or domain

You can redirect all requests to a website endpoint for a bucket to another bucket or domain. If you redirect all requests, any request made to the website endpoint is redirected to the specified bucket or domain.

For example, if your root domain is `example.com`, and you want to serve requests for both `http://example.com` and `http://www.example.com`, you must create two buckets named `example.com` and `www.example.com`. Then, maintain the content in the `example.com` bucket, and configure the other `www.example.com` bucket to redirect all requests to the `example.com` bucket. For more information, see [Configuring a Static Website Using a Custom Domain Name](#).

To redirect requests for a bucket website endpoint

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Under **Buckets**, choose the name of the bucket that you want to redirect requests from (for example, `www.example.com`).
3. Choose **Properties**.
4. Under **Static website hosting**, choose **Edit**.
5. Choose **Redirect requests for an object**.
6. In the **Host name** box, enter the website endpoint for your bucket or your custom domain.

For example, if you are redirecting to a root domain address, you would enter `example.com`.

7. For **Protocol**, choose the protocol for the redirected requests (`none`, `http`, or `https`).
If you do not specify a protocol, the default option is `none`.
8. Choose **Save changes**.

Configure redirection rules to use advanced conditional redirects

Using advanced redirection rules, you can route requests conditionally according to specific object key names, prefixes in the request, or response codes. For example, suppose that you delete or rename an object in your bucket. You can add a routing rule that redirects the request to another object. If you want to make a folder unavailable, you can add a routing rule to redirect the request to another webpage. You can also add a routing rule to handle error conditions by routing requests that return the error to another domain when the error is processed.

When enabling static website hosting for your bucket, you can optionally specify advanced redirection rules. Amazon S3 has a limitation of 50 routing rules per website configuration. If you require more than 50 routing rules, you can use object redirect. For more information, see [Using the S3 console](#).

For more information about configuring routing rules using the REST API, see [PutBucketWebsite](#) in the *Amazon Simple Storage Service API Reference*.

Important

To create redirection rules in the new Amazon S3 console, you must use JSON. For JSON examples, see [Redirection rules examples](#).

To configure redirection rules for a static website

To add redirection rules for a bucket that already has static website hosting enabled, follow these steps.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of a bucket that you have configured as a static website.
3. Choose **Properties**.
4. Under **Static website hosting**, choose **Edit**.
5. In **Redirection rules** box, enter your redirection rules in JSON.

In the S3 console you describe the rules using JSON. For JSON examples, see [Redirection rules examples](#). Amazon S3 has a limitation of 50 routing rules per website configuration.

6. Choose **Save changes**.

Routing rule elements

The following is general syntax for defining the routing rules in a website configuration in JSON and XML To configure redirection rules in the new S3 console, you must use JSON. For JSON examples, see [Redirection rules examples](#).

JSON

```
[  
  {  
    "Condition": {  
      "HttpErrorCodeReturnedEquals": "string",  
      "KeyPrefixEquals": "string"  
    },  
  },  
]
```

```
"Redirect": {  
    "HostName": "string",  
    "HttpRedirectCode": "string",  
    "Protocol": "http"|"https",  
    "ReplaceKeyPrefixWith": "string",  
    "ReplaceKeyWith": "string"  
}  
}  
]  
]
```

Note: Redirect must each have at least one child element. You can have either ReplaceKeyPrefix with or ReplaceKeyWith but not both.

XML

```
<RoutingRules> =  
  <RoutingRules>  
    <RoutingRule>...</RoutingRule>  
    [<RoutingRule>...</RoutingRule>  
     ...]  
  </RoutingRules>  
  
<RoutingRule> =  
  <RoutingRule>  
    [<Condition>...</Condition> ]  
    <Redirect>...</Redirect>  
  </RoutingRule>  
  
<Condition> =  
  <Condition>  
    [<KeyPrefixEquals>...</KeyPrefixEquals> ]  
    [<HttpErrorCodeReturnedEquals>...</HttpErrorCodeReturnedEquals> ]  
  </Condition>  
  Note: <Condition> must have at least one child element.  
  
<Redirect> =  
  <Redirect>  
    [<HostName>...</HostName> ]  
    [<Protocol>...</Protocol> ]  
    [<ReplaceKeyPrefixWith>...</ReplaceKeyPrefixWith> ]  
    [<ReplaceKeyWith>...</ReplaceKeyWith> ]  
    [<HttpRedirectCode>...</HttpRedirectCode> ]  
  </Redirect>
```

Note: <Redirect> must have at least one child element. You can have either ReplaceKeyPrefix with or ReplaceKeyWith but not both.

The following table describes the elements in the routing rule.

Name	Description
RoutingRules	Container for a collection of RoutingRule elements.
RoutingRule	A rule that identifies a condition and the redirect that is applied when the condition is met. Condition: <ul style="list-style-type: none">• A RoutingRules container must contain at least one routing rule.
Condition	Container for describing a condition that must be met for the specified redirect to be applied. If the routing rule does not include a condition, the rule is applied to all requests.
KeyPrefixEquals	The prefix of the object key name from which requests are redirected. KeyPrefixEquals is required if HttpStatusCodeReturnedEquals is not specified. If both KeyPrefixEquals and HttpStatusCodeReturnedEquals are specified, both must be true for the condition to be met.
HttpErrorCodeReturnedEquals	The HTTP error code that must match for the redirect to apply. If an error occurs, and if the error code meets this value, then the specified redirect applies.

Name	Description
	<code>HttpErrorCodeReturnedEquals</code> is required if <code>KeyPrefixEquals</code> is not specified. If both <code>KeyPrefixEquals</code> and <code>HttpErrorCodeReturnedEquals</code> are specified, both must be true for the condition to be met.
Redirect	Container element that provides instructions for redirecting the request. You can redirect requests to another host or another page, or you can specify another protocol to use. A <code>RoutingRule</code> must have a <code>Redirect</code> element. A <code>Redirect</code> element must contain at least one of the following sibling elements: <code>Protocol</code> , <code>HostName</code> , <code>ReplaceKeyPrefixWith</code> , <code>ReplaceKeyWith</code> , or <code>HttpRedirectCode</code> .
Protocol	The protocol, <code>http</code> or <code>https</code> , to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>Protocol</code> is not required.
HostName	The hostname to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>HostName</code> is not required.
ReplaceKeyPrefixWith	The prefix of the object key name that replaces the value of <code>KeyPrefixEquals</code> in the redirect request. If one of its siblings is supplied, <code>ReplaceKeyPrefixWith</code> is not required. It can be supplied only if <code>ReplaceKeyWith</code> is not supplied.

Name	Description
ReplaceKeyWith	<p>The object key to be used in the <code>Location</code> header that is returned in the response.</p> <p>If one of its siblings is supplied, <code>ReplaceKeyWith</code> is not required. It can be supplied only if <code>ReplaceKeyPrefixWith</code> is not supplied.</p>
HttpRedirectCode	<p>The HTTP redirect code to be used in the <code>Location</code> header that is returned in the response.</p> <p>If one of its siblings is supplied, <code>HttpRedirectCode</code> is not required.</p>

Redirection rules examples

The following examples explain common redirection tasks:

 **Important**

To create redirection rules in the new Amazon S3 console, you must use JSON.

Example 1: Redirect after renaming a key prefix

Suppose that your bucket contains the following objects:

- index.html
- docs/article1.html
- docs/article2.html

You decide to rename the folder from `docs/` to `documents/`. After you make this change, you need to redirect requests for prefix `docs/` to `documents/`. For example, request for `docs/article1.html` will be redirected to `documents/article1.html`.

In this case, you add the following routing rule to the website configuration.

JSON

```
[  
  {  
    "Condition": {  
      "KeyPrefixEquals": "docs/"  
    },  
    "Redirect": {  
      "ReplaceKeyPrefixWith": "documents/"  
    }  
  }  
]
```

XML

```
<RoutingRules>  
  <RoutingRule>  
    <Condition>  
      <KeyPrefixEquals>docs/</KeyPrefixEquals>  
    </Condition>  
    <Redirect>  
      <ReplaceKeyPrefixWith>documents/</ReplaceKeyPrefixWith>  
    </Redirect>  
  </RoutingRule>  
</RoutingRules>
```

Example 2: Redirect requests for a deleted folder to a page

Suppose that you delete the `images/` folder (that is, you delete all objects with the key prefix `images/`). You can add a routing rule that redirects requests for any object with the key prefix `images/` to a page named `folderdeleted.html`.

JSON

```
[  
  {  
    "Condition": {  
      "KeyPrefixEquals": "images/"  
    },  
    "Redirect": {  
      "ReplaceKeyWith": "folderdeleted.html"  
    }  
  }  
]
```

```
        }
    }
]
```

XML

```
<RoutingRules>
  <RoutingRule>
    <Condition>
      <KeyPrefixEquals>images/</KeyPrefixEquals>
    </Condition>
    <Redirect>
      <ReplaceKeyWith>folderdeleted.html</ReplaceKeyWith>
    </Redirect>
  </RoutingRule>
</RoutingRules>
```

Example 3: Redirect for an HTTP error

Suppose that when a requested object is not found, you want to redirect requests to an Amazon Elastic Compute Cloud (Amazon EC2) instance. Add a redirection rule so that when an HTTP status code 404 (Not Found) is returned, the site visitor is redirected to an Amazon EC2 instance that handles the request.

The following example also inserts the object key prefix `report-404/` in the redirect. For example, if you request a page `ExamplePage.html` and it results in an HTTP 404 error, the request is redirected to a page `report-404/ExamplePage.html` on the specified Amazon EC2 instance. If there is no routing rule and the HTTP error 404 occurs, the error document that is specified in the configuration is returned.

JSON

```
[
  {
    "Condition": {
      "HttpErrorCodeReturnedEquals": "404"
    },
    "Redirect": {
      "HostName": "ec2-11-22-333-44.compute-1.amazonaws.com",
      "ReplaceKeyPrefixWith": "report-404/"
```

```
        }
    }
]
```

XML

```
<RoutingRules>
  <RoutingRule>
    <Condition>
      <HttpErrorCodeReturnedEquals>404</HttpErrorCodeReturnedEquals>
    </Condition>
    <Redirect>
      <HostName>ec2-11-22-333-44.compute-1.amazonaws.com</HostName>
      <ReplaceKeyPrefixWith>report-404</ReplaceKeyPrefixWith>
    </Redirect>
  </RoutingRule>
</RoutingRules>
```

Redirect requests for an object

You can redirect requests for an object to another object or URL by setting the website redirect location in the metadata of the object. You set the redirect by adding the `x-amz-website-redirect-location` property to the object metadata. On the Amazon S3 console, you set the **Website Redirect Location** in the metadata of the object. If you use the [Amazon S3 API](#), you set `x-amz-website-redirect-location`. The website then interprets the object as a 301 redirect.

To redirect a request to another object, you set the redirect location to the key of the target object. To redirect a request to an external URL, you set the redirect location to the URL that you want. For more information about object metadata, see [System-defined object metadata](#).

When you set a page redirect, you can either keep or delete the source object content. For example, if you have a `page1.html` object in your bucket, you can redirect any requests for this page to another object, `page2.html`. You have two options:

- Keep the content of the `page1.html` object and redirect page requests.
- Delete the content of `page1.html` and upload a zero-byte object named `page1.html` to replace the existing object and redirect page requests.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you have configured as a static website (for example, example.com).
3. Under **Objects**, select your object.
4. Choose **Actions**, and choose **Edit metadata**.
5. Choose **Metadata**.
6. Choose **Add Metadata**.
7. Under **Type**, choose **System Defined**.
8. In **Key**, choose **x-amz-website-redirect-location**.
9. In **Value**, enter the key name of the object that you want to redirect to, for example, /page2.html.

For another object in the same bucket, the / prefix in the value is required. You can also set the value to an external URL, for example, http://www.example.com.

10. Choose **Edit metadata**.

Using the REST API

The following Amazon S3 API actions support the x-amz-website-redirect-location header in the request. Amazon S3 stores the header value in the object metadata as x-amz-website-redirect-location.

- [PUT Object](#)
- [Initiate Multipart Upload](#)
- [POST Object](#)
- [PUT Object - Copy](#)

A bucket configured for website hosting has both the website endpoint and the REST endpoint. A request for a page that is configured as a 301 redirect has the following possible outcomes, depending on the endpoint of the request:

- **Region-specific website endpoint** – Amazon S3 redirects the page request according to the value of the x-amz-website-redirect-location property.

- **REST endpoint** – Amazon S3 doesn't redirect the page request. It returns the requested object.

For more information about the endpoints, see [Key differences between a website endpoint and a REST API endpoint](#).

When setting a page redirect, you can either keep or delete the object content. For example, suppose that you have a `page1.html` object in your bucket.

- To keep the content of `page1.html` and only redirect page requests, you can submit a [PUT Object - Copy](#) request to create a new `page1.html` object that uses the existing `page1.html` object as the source. In your request, you set the `x-amz-website-redirect-location` header. When the request is complete, you have the original page with its content unchanged, but Amazon S3 redirects any requests for the page to the redirect location that you specify.
- To delete the content of the `page1.html` object and redirect requests for the page, you can send a PUT Object request to upload a zero-byte object that has the same object key: `page1.html`. In the PUT request, you set `x-amz-website-redirect-location` for `page1.html` to the new object. When the request is complete, `page1.html` has no content, and requests are redirected to the location that is specified by `x-amz-website-redirect-location`.

When you retrieve the object using the [GET Object](#) action, along with other object metadata, Amazon S3 returns the `x-amz-website-redirect-location` header in the response.

Developing with Amazon S3

This section covers developer-related topics for using Amazon S3. For more information, review the topics below.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [What is S3 Express One Zone?](#) and [Directory buckets](#).

Topics

- [Making requests](#)
- [Developing with Amazon S3 using the AWS CLI](#)

- [Developing with Amazon S3 using the REST API](#)
- [Handling REST and SOAP errors](#)
- [Developer reference](#)

Making requests

Amazon S3 is a REST service. You can send requests to Amazon S3 using the REST API or the AWS SDK (see [Sample Code and Libraries](#)) wrapper libraries that wrap the underlying Amazon S3 REST API, simplifying your programming tasks.

Every interaction with Amazon S3 is either authenticated or anonymous. Authentication is a process of verifying the identity of the requester trying to access an Amazon Web Services (AWS) product. Authenticated requests must include a signature value that authenticates the request sender. The signature value is, in part, generated from the requester's AWS access keys (access key ID and secret access key). For more information about getting access keys, see [How Do I Get Security Credentials?](#) in the [AWS General Reference](#).

If you are using the AWS SDK, the libraries compute the signature from the keys you provide. However, if you make direct REST API calls in your application, you must write the code to compute the signature and add it to the request.

Topics

- [About access keys](#)
- [Request endpoints](#)
- [Making requests to Amazon S3 over IPv6](#)
- [Making requests using the AWS SDKs](#)
- [Making requests using the REST API](#)

About access keys

The following sections review the types of access keys that you can use to make authenticated requests.

AWS account access keys

The account access keys provide full access to the AWS resources owned by the account. The following are examples of access keys:

- Access key ID (a 20-character, alphanumeric string). For example: AKIAIOSFODNN7EXAMPLE
- Secret access key (a 40-character string). For example: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY

The access key ID uniquely identifies an AWS account. You can use these access keys to send authenticated requests to Amazon S3.

IAM user access keys

You can create one AWS account for your company; however, there may be several employees in the organization who need access to your organization's AWS resources. Sharing your AWS account access keys reduces security, and creating individual AWS accounts for each employee might not be practical. Also, you cannot easily share resources such as buckets and objects because they are owned by different accounts. To share resources, you must grant permissions, which is additional work.

In such scenarios, you can use AWS Identity and Access Management (IAM) to create users under your AWS account with their own access keys and attach IAM user policies that grant appropriate resource access permissions to these users. To better manage these users, IAM enables you to create groups of users and grant group-level permissions that apply to all users in that group.

These users are referred to as IAM users that you create and manage within AWS. The parent account controls a user's ability to access AWS. Any resources an IAM user creates are under the control of and paid for by the parent AWS account. These IAM users can send authenticated requests to Amazon S3 using their own security credentials. For more information about creating and managing users under your AWS account, go to the [AWS Identity and Access Management product details page](#).

Temporary security credentials

In addition to creating IAM users with their own access keys, IAM also enables you to grant temporary security credentials (temporary access keys and a security token) to any IAM user to enable them to access your AWS services and resources. You can also manage users in your system outside AWS. These are referred to as federated users. Additionally, users can be applications that you create to access your AWS resources.

IAM provides the AWS Security Token Service API for you to request temporary security credentials. You can use either the AWS STS API or the AWS SDK to request these credentials. The API returns temporary security credentials (access key ID and secret access key), and a security token. These credentials are valid only for the duration you specify when you request them. You use the access key ID and secret key the same way you use them when sending requests using your AWS account or IAM user access keys. In addition, you must include the token in each request you send to Amazon S3.

An IAM user can request these temporary security credentials for their own use or hand them out to federated users or applications. When requesting temporary security credentials for federated users, you must provide a user name and an IAM policy defining the permissions you want to associate with these temporary security credentials. The federated user cannot get more permissions than the parent IAM user who requested the temporary credentials.

You can use these temporary security credentials in making requests to Amazon S3. The API libraries compute the necessary signature value using those credentials to authenticate your request. If you send requests using expired credentials, Amazon S3 denies the request.

For information on signing requests using temporary security credentials in your REST API requests, see [Signing and authenticating REST requests](#). For information about sending requests using AWS SDKs, see [Making requests using the AWS SDKs](#).

For more information about IAM support for temporary security credentials, see [Temporary Security Credentials](#) in the *IAM User Guide*.

For added security, you can require multifactor authentication (MFA) when accessing your Amazon S3 resources by configuring a bucket policy. For information, see [Requiring MFA](#). After you require MFA to access your Amazon S3 resources, the only way you can access these resources is by providing temporary credentials that are created with an MFA key. For more information, see the [AWS Multi-Factor Authentication](#) detail page and [Configuring MFA-Protected API Access](#) in the *IAM User Guide*.

Request endpoints

You send REST requests to the service's predefined endpoint. For a list of all AWS services and their corresponding endpoints, go to [Regions and Endpoints](#) in the *AWS General Reference*.

Making requests to Amazon S3 over IPv6

Amazon Simple Storage Service (Amazon S3) supports the ability to access S3 buckets using the Internet Protocol version 6 (IPv6), in addition to the IPv4 protocol. Amazon S3 dual-stack endpoints support requests to S3 buckets over IPv6 and IPv4. There are no additional charges for accessing Amazon S3 over IPv6. For more information about pricing, see [Amazon S3 Pricing](#).

Topics

- [Getting started making requests over IPv6](#)
- [Using IPv6 addresses in IAM policies](#)
- [Testing IP address compatibility](#)
- [Using Amazon S3 dual-stack endpoints](#)

Getting started making requests over IPv6

To make a request to an S3 bucket over IPv6, you need to use a dual-stack endpoint. The next section describes how to make requests over IPv6 by using dual-stack endpoints.

The following are some things you should know before trying to access a bucket over IPv6:

- The client and the network accessing the bucket must be enabled to use IPv6.
- Both virtual hosted-style and path style requests are supported for IPv6 access. For more information, see [Amazon S3 dual-stack endpoints](#).

- If you use source IP address filtering in your AWS Identity and Access Management (IAM) user or bucket policies, you need to update the policies to include IPv6 address ranges. For more information, see [Using IPv6 addresses in IAM policies](#).
- When using IPv6, server access log files output IP addresses in an IPv6 format. You need to update existing tools, scripts, and software that you use to parse Amazon S3 log files so that they can parse the IPv6 formatted Remote IP addresses. For more information, see [Amazon S3 server access log format](#) and [Logging requests with server access logging](#).

 **Note**

If you experience issues related to the presence of IPv6 addresses in log files, contact [AWS Support](#).

Making requests over IPv6 by using dual-stack endpoints

You make requests with Amazon S3 API calls over IPv6 by using dual-stack endpoints. The Amazon S3 API operations work the same way whether you're accessing Amazon S3 over IPv6 or over IPv4. Performance should be the same too.

When using the REST API, you access a dual-stack endpoint directly. For more information, see [Dual-stack endpoints](#).

When using the AWS Command Line Interface (AWS CLI) and AWS SDKs, you can use a parameter or flag to change to a dual-stack endpoint. You can also specify the dual-stack endpoint directly as an override of the Amazon S3 endpoint in the config file.

You can use a dual-stack endpoint to access a bucket over IPv6 from any of the following:

- The AWS CLI, see [Using dual-stack endpoints from the AWS CLI](#).
- The AWS SDKs, see [Using dual-stack endpoints from the AWS SDKs](#).
- The REST API, see [Making requests to dual-stack endpoints by using the REST API](#).

Features not available over IPv6

The following feature is currently not supported when accessing an S3 bucket over IPv6: Static website hosting from an S3 bucket.

Using IPv6 addresses in IAM policies

Before trying to access a bucket using IPv6, you must ensure that any IAM user or S3 bucket policies that are used for IP address filtering are updated to include IPv6 address ranges. IP address filtering policies that are not updated to handle IPv6 addresses may result in clients incorrectly losing or gaining access to the bucket when they start using IPv6. For more information about managing access permissions with IAM, see [Identity and access management in Amazon S3](#).

IAM policies that filter IP addresses use [IP Address Condition Operators](#). The following bucket policy identifies the 54.240.143.* range of allowed IPv4 addresses by using IP address condition operators. Any IP addresses outside of this range will be denied access to the bucket (examplebucket). Since all IPv6 addresses are outside of the allowed range, this policy prevents IPv6 addresses from being able to access examplebucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "IPAllow",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": "s3:*",  
            "Resource": "arn:aws:s3:::examplebucket/*",  
            "Condition": {  
                "IpAddress": {"aws:SourceIp": "54.240.143.0/24"}  
            }  
        }  
    ]  
}
```

You can modify the bucket policy's Condition element to allow both IPv4 (54.240.143.0/24) and IPv6 (2001:DB8:1234:5678::/64) address ranges as shown in the following example. You can use the same type of Condition block shown in the example to update both your IAM user and bucket policies.

```
"Condition": {  
    "IpAddress": {  
        "aws:SourceIp": [  
            "54.240.143.0/24",  
            "2001:DB8:1234:5678::/64"  
        ]  
    }  
}
```

```
    ]  
}  
}
```

Before using IPv6 you must update all relevant IAM user and bucket policies that use IP address filtering to allow IPv6 address ranges. We recommend that you update your IAM policies with your organization's IPv6 address ranges in addition to your existing IPv4 address ranges. For an example of a bucket policy that allows access over both IPv6 and IPv4, see [Restrict access to specific IP addresses](#).

You can review your IAM user policies using the IAM console at <https://console.aws.amazon.com/iam/>. For more information about IAM, see the [IAM User Guide](#). For information about editing S3 bucket policies, see [Adding a bucket policy by using the Amazon S3 console](#).

Testing IP address compatibility

If you are using use Linux/Unix or Mac OS X, you can test whether you can access a dual-stack endpoint over IPv6 by using the `curl` command as shown in the following example:

Example

```
curl -v http://s3.dualstack.us-west-2.amazonaws.com/
```

You get back information similar to the following example. If you are connected over IPv6 the connected IP address will be an IPv6 address.

```
* About to connect() to s3-us-west-2.amazonaws.com port 80 (#0)  
* Trying IPv6 address... connected  
* Connected to s3.dualstack.us-west-2.amazonaws.com (IPv6 address) port 80 (#0)  
> GET / HTTP/1.1  
> User-Agent: curl/7.18.1 (x86_64-unknown-linux-gnu) libcurl/7.18.1 OpenSSL/1.0.1t  
zlib/1.2.3  
> Host: s3.dualstack.us-west-2.amazonaws.com
```

If you are using Microsoft Windows 7 or Windows 10, you can test whether you can access a dual-stack endpoint over IPv6 or IPv4 by using the `ping` command as shown in the following example.

```
ping ipv6.s3.dualstack.us-west-2.amazonaws.com
```

Using Amazon S3 dual-stack endpoints

Amazon S3 dual-stack endpoints support requests to S3 buckets over IPv6 and IPv4. This section describes how to use dual-stack endpoints.

Topics

- [Amazon S3 dual-stack endpoints](#)
- [Using dual-stack endpoints from the AWS CLI](#)
- [Using dual-stack endpoints from the AWS SDKs](#)
- [Using dual-stack endpoints from the REST API](#)

Amazon S3 dual-stack endpoints

When you make a request to a dual-stack endpoint, the bucket URL resolves to an IPv6 or an IPv4 address. For more information about accessing a bucket over IPv6, see [Making requests to Amazon S3 over IPv6](#).

When using the REST API, you directly access an Amazon S3 endpoint by using the endpoint name (URI). You can access an S3 bucket through a dual-stack endpoint by using a virtual hosted-style or a path-style endpoint name. Amazon S3 supports only regional dual-stack endpoint names, which means that you must specify the region as part of the name.

Use the following naming conventions for the dual-stack virtual hosted-style and path-style endpoint names:

- Virtual hosted-style dual-stack endpoint:

*bucketname.s3.dualstack.**aws-region**.amazonaws.com*

- Path-style dual-stack endpoint:

*s3.dualstack.**aws-region**.amazonaws.com/**bucketname***

For more information, about endpoint name style, see [Accessing and listing an Amazon S3 bucket](#).

For a list of Amazon S3 endpoints, see [Regions and Endpoints](#) in the *AWS General Reference*.

Important

You can use transfer acceleration with dual-stack endpoints. For more information, see [Getting started with Amazon S3 Transfer Acceleration](#).

Note

The two types of VPC endpoints to access Amazon S3 (*Interface VPC endpoints* and *Gateway VPC endpoints*) don't have dual-stack support. For more information about VPC endpoints for Amazon S3, see [AWS PrivateLink for Amazon S3](#).

When using the AWS Command Line Interface (AWS CLI) and AWS SDKs, you can use a parameter or flag to change to a dual-stack endpoint. You can also specify the dual-stack endpoint directly as an override of the Amazon S3 endpoint in the config file. The following sections describe how to use dual-stack endpoints from the AWS CLI and the AWS SDKs.

Using dual-stack endpoints from the AWS CLI

This section provides examples of AWS CLI commands used to make requests to a dual-stack endpoint. For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#).

You set the configuration value `use_dualstack_endpoint` to `true` in a profile in your AWS Config file to direct all Amazon S3 requests made by the `s3` and `s3api` AWS CLI commands to the dual-stack endpoint for the specified region. You specify the region in the config file or in a command using the `--region` option.

When using dual-stack endpoints with the AWS CLI, both path and virtual addressing styles are supported. The addressing style, set in the config file, controls if the bucket name is in the hostname or part of the URL. By default, the CLI will attempt to use virtual style where possible, but will fall back to path style if necessary. For more information, see [AWS CLI Amazon S3 Configuration](#).

You can also make configuration changes by using a command, as shown in the following example, which sets `use_dualstack_endpoint` to `true` and `addressing_style` to `virtual` in the default profile.

```
$ aws configure set default.s3.use_dualstack_endpoint true  
$ aws configure set default.s3.addressing_style virtual
```

If you want to use a dual-stack endpoint for specified AWS CLI commands only (not all commands), you can use either of the following methods:

- You can use the dual-stack endpoint per command by setting the `--endpoint-url` parameter to `https://s3.dualstack.aws-region.amazonaws.com` or `http://s3.dualstack.aws-region.amazonaws.com` for any `s3` or `s3api` command.

```
$ aws s3api list-objects --bucket bucketname --endpoint-url https://s3.dualstack.aws-region.amazonaws.com
```

- You can set up separate profiles in your AWS Config file. For example, create one profile that sets `use_dualstack_endpoint` to `true` and a profile that does not set `use_dualstack_endpoint`. When you run a command, specify which profile you want to use, depending upon whether or not you want to use the dual-stack endpoint.

Note

When using the AWS CLI you currently cannot use transfer acceleration with dual-stack endpoints. However, support for the AWS CLI is coming soon. For more information, see [Using the AWS CLI](#).

Using dual-stack endpoints from the AWS SDKs

This section provides examples of how to access a dual-stack endpoint by using the AWS SDKs.

AWS SDK for Java dual-stack endpoint example

The following example shows how to enable dual-stack endpoints when creating an Amazon S3 client using the AWS SDK for Java.

For instructions on creating and testing a working Java sample, see [Testing the Amazon S3 Java Code Examples](#).

```
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;
```

```
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;

public class DualStackEndpoints {

    public static void main(String[] args) {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";

        try {
            // Create an Amazon S3 client with dual-stack endpoints enabled.
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(clientRegion)
                .withDualstackEnabled(true)
                .build();

            s3Client.listObjects(bucketName);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

If you are using the AWS SDK for Java on Windows, you might have to set the following Java virtual machine (JVM) property:

```
java.net.preferIPv6Addresses=true
```

AWS .NET SDK dual-stack endpoint example

When using the AWS SDK for .NET you use the `AmazonS3Config` class to enable the use of a dual-stack endpoint as shown in the following example.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class DualStackEndpointTest
    {
        private const string bucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion = RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            var config = new AmazonS3Config
            {
                UseDualstackEndpoint = true,
                RegionEndpoint = bucketRegion
            };
            client = new AmazonS3Client(config);
            Console.WriteLine("Listing objects stored in a bucket");
            ListingObjectsAsync().Wait();
        }

        private static async Task ListingObjectsAsync()
        {
            try
            {
                var request = new ListObjectsV2Request
                {
                    BucketName = bucketName,
                    MaxKeys = 10
                };
                ListObjectsV2Response response;
                do
                {
                    response = await client.ListObjectsV2Async(request);

                    // Process the response.
                    foreach (S3Object entry in response.S3Objects)
```

```
        {
            Console.WriteLine("key = {0} size = {1}",
                entry.Key, entry.Size);
        }
        Console.WriteLine("Next Continuation Token: {0}",
response.NextContinuationToken);
        request.ContinuationToken = response.NextContinuationToken;
    } while (response.IsTruncated == true);
}
catch (AmazonS3Exception amazonS3Exception)
{
    Console.WriteLine("An AmazonS3Exception was thrown. Exception: " +
amazonS3Exception.ToString());
}
catch (Exception e)
{
    Console.WriteLine("Exception: " + e.ToString());
}
}
}
}
```

For a full .NET sample for listing objects, see [Listing object keys programmatically](#).

For information about how to create and test a working .NET sample, see [Running the Amazon S3 .NET Code Examples](#).

Using dual-stack endpoints from the REST API

For information about making requests to dual-stack endpoints by using the REST API, see [Making requests to dual-stack endpoints by using the REST API](#).

Making requests using the AWS SDKs

Topics

- [Making requests using AWS account or IAM user credentials](#)
- [Making requests using IAM user temporary credentials](#)
- [Making requests using federated user temporary credentials](#)

You can send authenticated requests to Amazon S3 using either the AWS SDK or by making the REST API calls directly in your application. The AWS SDK API uses the credentials that you provide to compute the signature for authentication. If you use the REST API directly in your applications, you must write the necessary code to compute the signature for authenticating your request. For a list of available AWS SDKs go to, [Sample Code and Libraries](#).

Making requests using AWS account or IAM user credentials

You can use your AWS account or IAM user security credentials to send authenticated requests to Amazon S3. This section provides examples of how you can send authenticated requests using the AWS SDK for Java, AWS SDK for .NET, and AWS SDK for PHP. For a list of available AWS SDKs, go to [Sample Code and Libraries](#).

Each of these AWS SDKs uses an SDK-specific credentials provider chain to find and use credentials and perform actions on behalf of the credentials owner. What all these credentials provider chains have in common is that they all look for your local AWS credentials file.

For more information, see the topics below:

Topics

- [To create a local AWS credentials file](#)
- [Sending authenticated requests using the AWS SDKs](#)
- [Related resources](#)

To create a local AWS credentials file

The easiest way to configure credentials for your AWS SDKs is to use an AWS credentials file. If you use the AWS Command Line Interface (AWS CLI), you may already have a local AWS credentials file configured. Otherwise, use the following procedure to set up a credentials file:

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Create a new user with permissions limited to the services and actions that you want your code to have access to. For more information about creating a new user, see [Creating IAM users \(Console\)](#), and follow the instructions through step 8.
3. Choose **Download .csv** to save a local copy of your AWS credentials.
4. On your computer, navigate to your home directory, and create an .aws directory. On Unix-based systems, such as Linux or OS X, this is in the following location:

```
~/.aws
```

On Windows, this is in the following location:

```
%HOMEPATH%\aws
```

5. In the .aws directory, create a new file named `credentials`.
6. Open the `credentials.csv` file that you downloaded from the IAM console, and copy its contents into the `credentials` file using the following format:

```
[default]
aws_access_key_id = your_access_key_id
aws_secret_access_key = your_secret_access_key
```

7. Save the `credentials` file, and delete the `.csv` file that you downloaded in step 3.

Your shared credentials file is now configured on your local computer, and it's ready to be used with the AWS SDKs.

Sending authenticated requests using the AWS SDKs

Use the AWS SDKs to send authenticated requests. For more information about sending authenticated requests, see [AWS security credentials](#) or [IAM Identity Center Authentication](#).

Java

To send authenticated requests to Amazon S3 using your AWS account or IAM user credentials, do the following:

- Use the `AmazonS3ClientBuilder` class to create an `AmazonS3Client` instance.

- Run one of the AmazonS3Client methods to send requests to Amazon S3. The client generates the necessary signature from the credentials that you provide and includes it in the request.

The following example performs the preceding tasks. For information on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

Example

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.ListObjectsRequest;
import com.amazonaws.services.s3.model.ObjectListing;
import com.amazonaws.services.s3.model.S3ObjectSummary;

import java.io.IOException;
import java.util.List;

public class MakingRequests {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "**** Bucket name ****";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(clientRegion)
                .build();

            // Get a list of objects in the bucket, two at a time, and
            // print the name and size of each object.
            ListObjectsRequest listRequest = new
            ListObjectsRequest().withBucketName(bucketName).withMaxKeys(2);
            ObjectListing objects = s3Client.listObjects(listRequest);
            while (true) {
                List<S3ObjectSummary> summaries = objects.getObjectSummaries();
```

```
        for (S3ObjectSummary summary : summaries) {
            System.out.printf("Object \"%s\" retrieved with size %d\n",
summary.getKey(), summary.getSize());
        }
        if (objects.isTruncated()) {
            objects = s3Client.listNextBatchOfObjects(objects);
        } else {
            break;
        }
    }
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

.NET

To send authenticated requests using your AWS account or IAM user credentials:

- Create an instance of the `AmazonS3Client` class.
- Run one of the `AmazonS3Client` methods to send requests to Amazon S3. The client generates the necessary signature from the credentials that you provide and includes it in the request it sends to Amazon S3.

For more information, see [Making requests using AWS account or IAM user credentials](#).

Note

- You can create the `AmazonS3Client` client without providing your security credentials. Requests sent using this client are anonymous requests, without a signature. Amazon S3 returns an error if you send anonymous requests for a resource that is not publicly available.

- You can create an AWS account and create the required users. You can also manage credentials for those users. You need these credentials to perform the task in the following example. For more information, see [Configure AWS credentials](#) in the *AWS SDK for .NET Developer Guide*.

You can then also configure your application to actively retrieve profiles and credentials, and then explicitly use those credentials when creating an AWS service client. For more information, see [Accessing credentials and profiles in an application](#) in the *AWS SDK for .NET Developer Guide*.

The following C# example shows how to perform the preceding tasks. For information about running the .NET examples in this guide and for instructions on how to store your credentials in a configuration file, see [Running the Amazon S3 .NET Code Examples](#).

Example

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class MakeS3RequestTest
    {
        private const string bucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            using (client = new AmazonS3Client(bucketRegion))
            {
                Console.WriteLine("Listing objects stored in a bucket");
                ListingObjectsAsync().Wait();
            }
        }
    }
}
```

```
static async Task ListingObjectsAsync()
{
    try
    {
        ListObjectsRequest request = new ListObjectsRequest
        {
            BucketName = bucketName,
            MaxKeys = 2
        };
        do
        {
            ListObjectsResponse response = await
client.ListObjectsAsync(request);
            // Process the response.
            foreach (S3Object entry in response.S3Objects)
            {
                Console.WriteLine("key = {0} size = {1}",
                    entry.Key, entry.Size);
            }

            // If the response is truncated, set the marker to get the next
            // set of keys.
            if (response.IsTruncated)
            {
                request.Marker = response.NextMarker;
            }
            else
            {
                request = null;
            }
        } while (request != null);
    }
    catch (AmazonS3Exception e)
    {
        Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
    catch (Exception e)
    {
        Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
}
```

```
    }  
}
```

For working examples, see [Amazon S3 objects overview](#) and [Buckets overview](#). You can test these examples using your AWS account or an IAM user credentials.

For example, to list all the object keys in your bucket, see [Listing object keys programmatically](#).

PHP

This section explains how to use a class from version 3 of the AWS SDK for PHP to send authenticated requests using your AWS account or IAM user credentials. It assumes that you are already following the instructions for [Using the AWS SDK for PHP and Running PHP Examples](#) and have the AWS SDK for PHP properly installed.

The following PHP example shows how the client makes a request using your security credentials to list all of the buckets for your account.

Example

```
require 'vendor/autoload.php';  
  
use Aws\Sts\StsClient;  
use Aws\S3\S3Client;  
use Aws\S3\Exception\S3Exception;  
  
$bucket = '*** Your Bucket Name ***';  
  
$s3 = new S3Client([  
    'region' => 'us-east-1',  
    'version' => 'latest',  
]);  
  
// Retrieve the list of buckets.  
$result = $s3->listBuckets();  
  
try {  
    // Retrieve a paginator for listing objects.  
    $objects = $s3->getPaginator('ListObjects', [  
        'Bucket' => $bucket  
    ]);
```

```
echo "Keys retrieved!" . PHP_EOL;

// Print the list of objects to the page.
foreach ($objects as $object) {
    echo $object['Key'] . PHP_EOL;
}
} catch (S3Exception $e) {
    echo $e->getMessage() . PHP_EOL;
}
```

Note

You can create the `S3Client` client without providing your security credentials.

Requests sent using this client are anonymous requests, without a signature. Amazon S3 returns an error if you send anonymous requests for a resource that is not publicly available. For more information, see [Creating Anonymous Clients](#) in the [AWS SDK for PHP Documentation](#).

For working examples, see [Amazon S3 objects overview](#). You can test these examples using your AWS account or IAM user credentials.

For an example of listing object keys in a bucket, see [Listing object keys programmatically](#).

Ruby

Before you can use version 3 of the AWS SDK for Ruby to make calls to Amazon S3, you must set the AWS access credentials that the SDK uses to verify your access to your buckets and objects. If you have shared credentials set up in the AWS credentials profile on your local system, version 3 of the SDK for Ruby can use those credentials without your having to declare them in your code. For more information about setting up shared credentials, see [Making requests using AWS account or IAM user credentials](#).

The following Ruby code snippet uses the credentials in a shared AWS credentials file on a local computer to authenticate a request to get all of the object key names in a specific bucket. It does the following:

1. Creates an instance of the `Aws::S3::Client` class.
2. Makes a request to Amazon S3 by enumerating objects in a bucket using the `list_objects_v2` method of `Aws::S3::Client`. The client generates the necessary

signature value from the credentials in the AWS credentials file on your computer, and includes it in the request it sends to Amazon S3.

3. Prints the array of object key names to the terminal.

Example

```
# Prerequisites:  
# - An existing Amazon S3 bucket.  
  
require "aws-sdk-s3"  
  
# @param s3_client [Aws::S3::Client] An initialized Amazon S3 client.  
# @param bucket_name [String] The bucket's name.  
# @return [Boolean] true if all operations succeed; otherwise, false.  
# @example  
#   s3_client = Aws::S3::Client.new(region: 'us-west-2')  
#   exit 1 unless list_bucket_objects?(s3_client, 'doc-example-bucket')  
def list_bucket_objects?(s3_client, bucket_name)  
  puts "Accessing the bucket named '#{bucket_name}'..."  
  objects = s3_client.list_objects_v2(  
    bucket: bucket_name,  
    max_keys: 50  
  )  
  
  if objects.count.positive?  
    puts "The object keys in this bucket are (first 50 objects):"  
    objects.contents.each do |object|  
      puts object.key  
    end  
  else  
    puts "No objects found in this bucket."  
  end  
  
  return true  
rescue StandardError => e  
  puts "Error while accessing the bucket named '#{bucket_name}': #{e.message}"  
  return false  
end  
  
# Full example call:  
# Replace us-west-2 with the AWS Region you're using for Amazon S3.
```

```
def run_me
  region = "us-west-2"
  bucket_name = "BUCKET_NAME"
  s3_client = Aws::S3::Client.new(region: region)

  exit 1 unless list_bucket_objects?(s3_client, bucket_name)
end

run_me if $PROGRAM_NAME == __FILE__
```

If you don't have a local AWS credentials file, you can still create the `Aws::S3::Client` resource and run code against Amazon S3 buckets and objects. Requests that are sent using version 3 of the SDK for Ruby are anonymous, with no signature by default. Amazon S3 returns an error if you send anonymous requests for a resource that's not publicly available.

You can use and expand the previous code snippet for SDK for Ruby applications, as in the following more robust example.

```
# Prerequisites:
# - An existing Amazon S3 bucket.

require "aws-sdk-s3"

# @param s3_client [Aws::S3::Client] An initialized Amazon S3 client.
# @param bucket_name [String] The bucket's name.
# @return [Boolean] true if all operations succeed; otherwise, false.
# @example
#   s3_client = Aws::S3::Client.new(region: 'us-west-2')
#   exit 1 unless list_bucket_objects?(s3_client, 'doc-example-bucket')
def list_bucket_objects?(s3_client, bucket_name)
  puts "Accessing the bucket named '#{bucket_name}'..."
  objects = s3_client.list_objects_v2(
    bucket: bucket_name,
    max_keys: 50
  )

  if objects.count.positive?
    puts "The object keys in this bucket are (first 50 objects):"
    objects.contents.each do |object|
      puts object.key
    end
  end
end
```

```
else
    puts "No objects found in this bucket."
end

return true
rescue StandardError => e
    puts "Error while accessing the bucket named '#{bucket_name}': #{e.message}"
    return false
end

# Full example call:
# Replace us-west-2 with the AWS Region you're using for Amazon S3.
def run_me
    region = "us-west-2"
    bucket_name = "BUCKET_NAME"
    s3_client = Aws::S3::Client.new(region: region)

    exit 1 unless list_bucket_objects?(s3_client, bucket_name)
end

run_me if $PROGRAM_NAME == __FILE__
```

Go

Example

The following example uses AWS credentials automatically loaded by the SDK for Go from the shared credentials file.

```
package main

import (
    "context"
    "fmt"

    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/s3"
)

// main uses the AWS SDK for Go V2 to create an Amazon Simple Storage Service
// (Amazon S3) client and list up to 10 buckets in your account.
// This example uses the default settings specified in your shared credentials
```

```
// and config files.

func main() {
    sdkConfig, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        fmt.Println("Couldn't load default configuration. Have you set up your AWS
account?")
        fmt.Println(err)
        return
    }
    s3Client := s3.NewFromConfig(sdkConfig)
    count := 10
    fmt.Printf("Let's list up to %v buckets for your account.\n", count)
    result, err := s3Client.ListBuckets(context.TODO(), &s3.ListBucketsInput{})
    if err != nil {
        fmt.Printf("Couldn't list buckets for your account. Here's why: %v\n", err)
        return
    }
    if len(result.Buckets) == 0 {
        fmt.Println("You don't have any buckets!")
    } else {
        if count > len(result.Buckets) {
            count = len(result.Buckets)
        }
        for _, bucket := range result.Buckets[:count] {
            fmt.Printf("\t%v\n", *bucket.Name)
        }
    }
}
```

Making requests using IAM user temporary credentials

An AWS account or an IAM user can request temporary security credentials and use them to send authenticated requests to Amazon S3. This section provides examples of how to use the AWS SDK for Java, .NET, and PHP to obtain temporary security credentials and use them to authenticate your requests to Amazon S3.

Java

An IAM user or an AWS account can request temporary security credentials (see [Making requests](#)) using the AWS SDK for Java and use them to access Amazon S3. These credentials expire after the specified session duration.

By default, the session duration is one hour. If you use IAM user credentials, you can specify the duration when requesting the temporary security credentials from 15 minutes to the maximum session duration for the role. For more information about temporary security credentials, see [Temporary Security Credentials](#) in the *IAM User Guide*. For more information about making requests, see [Making requests](#).

To get temporary security credentials and access Amazon S3

1. Create an instance of the `AWSecurityTokenService` class. For information about providing credentials, see [Developing with Amazon S3 using the AWS SDKs, and explorers](#).
2. Retrieve the temporary security credentials for the desired role by calling the `assumeRole()` method of the Security Token Service (STS) client.
3. Package the temporary security credentials into a `BasicSessionCredentials` object. You use this object to provide the temporary security credentials to your Amazon S3 client.
4. Create an instance of the `AmazonS3Client` class using the temporary security credentials. You send requests to Amazon S3 using this client. If you send requests using expired credentials, Amazon S3 will return an error.

 **Note**

If you obtain temporary security credentials using your AWS account security credentials, the temporary credentials are valid for only one hour. You can specify the session duration only if you use IAM user credentials to request a session.

The following example lists a set of object keys in the specified bucket. The example obtains temporary security credentials for a session and uses them to send an authenticated request to Amazon S3.

If you want to test the sample by using IAM user credentials, you must create an IAM user under your AWS account. For more information about how to create an IAM user, see [Creating Your First IAM user and Administrators Group](#) in the *IAM User Guide*.

For instructions on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

you
// just retrieved.
BasicSessionCredentials awsCredentials = new BasicSessionCredentials(
    sessionCredentials.getAccessKeyId(),
    sessionCredentials.getSecretAccessKey(),
    sessionCredentials.getSessionToken());

// Provide temporary security credentials so that the Amazon S3 client
// can send authenticated requests to Amazon S3. You create the client
// using the sessionCredentials object.
AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
    .withCredentials(new
AWSStaticCredentialsProvider(awsCredentials))
    .withRegion(clientRegion)
    .build();

// Verify that assuming the role worked and the permissions are set
correctly
// by getting a set of object keys from the bucket.
ObjectListing objects = s3Client.listObjects(bucketName);
System.out.println("No. of Objects: " +
objects.getObjectSummaries().size());
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
```

```
}
```

.NET

An IAM user or an AWS account can request temporary security credentials using the AWS SDK for .NET and use them to access Amazon S3. These credentials expire after the session duration.

By default, the session duration is one hour. If you use IAM user credentials, you can specify the duration when requesting the temporary security credentials from 15 minutes to the maximum session duration for the role. For more information about temporary security credentials, see [Temporary Security Credentials](#) in the *IAM User Guide*. For more information about making requests, see [Making requests](#).

To get temporary security credentials and access Amazon S3

1. Create an instance of the AWS Security Token Service client, `AmazonSecurityTokenServiceClient`. For information about providing credentials, see [Developing with Amazon S3 using the AWS SDKs, and explorers](#).
2. Start a session by calling the `GetSessionToken` method of the STS client you created in the preceding step. You provide session information to this method using a `GetSessionTokenRequest` object.

The method returns your temporary security credentials.

3. Package the temporary security credentials in an instance of the `SessionAWSCredentials` object. You use this object to provide the temporary security credentials to your Amazon S3 client.
4. Create an instance of the `AmazonS3Client` class by passing in the temporary security credentials. You send requests to Amazon S3 using this client. If you send requests using expired credentials, Amazon S3 returns an error.

Note

If you obtain temporary security credentials using your AWS account security credentials, those credentials are valid for only one hour. You can specify a session duration only if you use IAM user credentials to request a session.

The following C# example lists object keys in the specified bucket. For illustration, the example obtains temporary security credentials for a default one-hour session and uses them to send authenticated request to Amazon S3.

If you want to test the sample by using IAM user credentials, you must create an IAM user under your AWS account. For more information about how to create an IAM user, see [Creating Your First IAM user and Administrators Group](#) in the *IAM User Guide*. For more information about making requests, see [Making requests](#).

For instructions on creating and testing a working example, see [Running the Amazon S3 .NET Code Examples](#).

    Console.WriteLine(stsException.Message,
stsException.InnerException);
}
}

private static async Task<SessionAWSCredentials>
GetTemporaryCredentialsAsync()
{
    using (var stsClient = new AmazonSecurityTokenServiceClient())
{
    var getSessionTokenRequest = new GetSessionTokenRequest
    {
        DurationSeconds = 7200 // seconds
    };

    GetSessionTokenResponse sessionTokenResponse =
        await
stsClient.GetSessionTokenAsync(getSessionTokenRequest);

    Credentials credentials = sessionTokenResponse.Credentials;
```

```
        var sessionCredentials =
            new SessionAWSCredentials(credentials.AccessKeyId,
                                      credentials.SecretAccessKey,
                                      credentials.SessionToken);
        return sessionCredentials;
    }
}
}
```

PHP

This example assumes that you are already following the instructions for [Using the AWS SDK for PHP and Running PHP Examples](#) and have the AWS SDK for PHP properly installed.

An IAM user or an AWS account can request temporary security credentials using version 3 of the AWS SDK for PHP. It can then use the temporary credentials to access Amazon S3. The credentials expire when the session duration expires.

By default, the session duration is one hour. If you use IAM user credentials, you can specify the duration when requesting the temporary security credentials from 15 minutes to the maximum session duration for the role. For more information about temporary security credentials, see [Temporary Security Credentials](#) in the *IAM User Guide*. For more information about making requests, see [Making requests](#).

Note

If you obtain temporary security credentials using your AWS account security credentials, the temporary security credentials are valid for only one hour. You can specify the session duration only if you use IAM user credentials to request a session.

Example

The following PHP example lists object keys in the specified bucket using temporary security credentials. The example obtains temporary security credentials for a default one-hour session, and uses them to send authenticated request to Amazon S3. For information about running the PHP examples in this guide, see [Running PHP Examples](#).

If you want to test the example by using IAM user credentials, you must create an IAM user under your AWS account. For information about how to create an IAM user, see [Creating Your First IAM user and Administrators Group](#) in the *IAM User Guide*. For examples of setting the session duration when using IAM user credentials to request a session, see [Making requests using IAM user temporary credentials](#).

```
require 'vendor/autoload.php';

use Aws\Sts\StsClient;
use Aws\S3\S3Client;
use Aws\S3\Exception\S3Exception;

$bucket = '*** Your Bucket Name ***';

$sts = new StsClient([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

$sessionToken = $sts->getSessionToken();

$s3 = new S3Client([
    'region'  => 'us-east-1',
    'version' => 'latest',
    'credentials' => [
        'key'      => $sessionToken['Credentials']['AccessKeyId'],
        'secret'   => $sessionToken['Credentials']['SecretAccessKey'],
        'token'    => $sessionToken['Credentials']['SessionToken']
    ]
]);

$result = $s3->listBuckets();

try {
    // Retrieve a paginator for listing objects.
    $objects = $s3->getPaginator('ListObjects', [
        'Bucket' => $bucket
    ]);

    echo "Keys retrieved!" . PHP_EOL;

    // List objects
```

```
foreach ($objects as $object) {  
    echo $object['Key'] . PHP_EOL;  
}  
} catch (S3Exception $e) {  
    echo $e->getMessage() . PHP_EOL;  
}
```

Ruby

An IAM user or an AWS account can request temporary security credentials using AWS SDK for Ruby and use them to access Amazon S3. These credentials expire after the session duration.

By default, the session duration is one hour. If you use IAM user credentials, you can specify the duration when requesting the temporary security credentials from 15 minutes to the maximum session duration for the role. For more information about temporary security credentials, see [Temporary Security Credentials](#) in the *IAM User Guide*. For more information about making requests, see [Making requests](#).

Note

If you obtain temporary security credentials using your AWS account security credentials, the temporary security credentials are valid for only one hour. You can specify session duration only if you use IAM user credentials to request a session.

The following Ruby example creates a temporary user to list the items in a specified bucket for one hour. To use this example, you must have AWS credentials that have the necessary permissions to create new AWS Security Token Service (AWS STS) clients, and list Amazon S3 buckets.

```
# Prerequisites:  
# - A user in AWS Identity and Access Management (IAM). This user must  
#   be able to assume the following IAM role. You must run this code example  
#   within the context of this user.  
# - An existing role in IAM that allows all of the Amazon S3 actions for all of the  
#   resources in this code example. This role must also trust the preceding IAM  
#   user.  
# - An existing S3 bucket.  
  
require "aws-sdk-core"
```

```
require "aws-sdk-s3"
require "aws-sdk-iam"

Making requests using federated user temporary credentials

You can request temporary security credentials and provide them to your federated users or applications who need to access your AWS resources. This section provides examples of how you can use the AWS SDK to obtain temporary security credentials for your federated users or applications and send authenticated requests to Amazon S3 using those credentials. For a list of available AWS SDKs, see [Sample Code and Libraries](#).

Note

Both the AWS account and an IAM user can request temporary security credentials for federated users. However, for added security, only an IAM user with the necessary permissions should request these temporary credentials to ensure that the federated user gets at most the permissions of the requesting IAM user. In some applications, you might find it suitable to create an IAM user with specific permissions for the sole purpose of granting temporary security credentials to your federated users and applications.

Java

You can provide temporary security credentials for your federated users and applications so that they can send authenticated requests to access your AWS resources. When requesting these temporary credentials, you must provide a user name and an IAM policy that describes the resource permissions that you want to grant. By default, the session duration is one hour. You can explicitly set a different duration value when requesting the temporary security credentials for federated users and applications.

Note

For added security when requesting temporary security credentials for federated users and applications, we recommend that you use a dedicated IAM user with only the necessary access permissions. The temporary user you create can never get more permissions than the IAM user who requested the temporary security credentials. For more information, see [AWS Identity and Access Management FAQs](#).

To provide security credentials and send authenticated request to access resources, do the following:

- Create an instance of the `AWSecurityTokenServiceClient` class. For information about providing credentials, see [Using the AWS SDK for Java](#).
- Start a session by calling the `getFederationToken()` method of the Security Token Service (STS) client. Provide session information, including the user name and an IAM policy, that you want to attach to the temporary credentials. You can provide an optional session duration. This method returns your temporary security credentials.
- Package the temporary security credentials in an instance of the `BasicSessionCredentials` object. You use this object to provide the temporary security credentials to your Amazon S3 client.
- Create an instance of the `AmazonS3Client` class using the temporary security credentials. You send requests to Amazon S3 using this client. If you send requests using expired credentials, Amazon S3 returns an error.

Example

The example lists keys in the specified S3 bucket. In the example, you obtain temporary security credentials for a two-hour session for your federated user and use the credentials to send authenticated requests to Amazon S3. To run the example, you need to create an IAM user with an attached policy that allows the user to request temporary security credentials and list your AWS resources. The following policy accomplishes this:

```
{  
    "Statement": [  
        {  
            "Action": ["s3>ListBucket",  
                      "sts:GetFederationToken*"  
            ],  
            "Effect": "Allow",  
            "Resource": "*"  
        }  
    ]  
}
```

For more information about how to create an IAM user, see [Creating Your First IAM user and Administrators Group](#) in the *IAM User Guide*.

After creating an IAM user and attaching the preceding policy, you can run the following example. For instructions on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

    // it, so it returned an error response.  
    e.printStackTrace();  
} catch (SdkClientException e) {  
    // Amazon S3 couldn't be contacted for a response, or the client  
    // couldn't parse the response from Amazon S3.  
    e.printStackTrace();  
}  
}  
}
```

.NET

You can provide temporary security credentials for your federated users and applications so that they can send authenticated requests to access your AWS resources. When requesting these temporary credentials, you must provide a user name and an IAM policy that describes the resource permissions that you want to grant. By default, the duration of a session is one hour. You can explicitly set a different duration value when requesting the temporary security credentials for federated users and applications. For information about sending authenticated requests, see [Making requests](#).

 **Note**

When requesting temporary security credentials for federated users and applications, for added security, we suggest that you use a dedicated IAM user with only the necessary access permissions. The temporary user you create can never get more permissions than the IAM user who requested the temporary security credentials. For more information, see [AWS Identity and Access Management FAQs](#).

You do the following:

- Create an instance of the AWS Security Token Service client, `AmazonSecurityTokenServiceClient` class. For information about providing credentials, see [Using the AWS SDK for .NET](#).
- Start a session by calling the `GetFederationToken` method of the STS client. You need to provide session information, including the user name and an IAM policy that you want to attach to the temporary credentials. Optionally, you can provide a session duration. This method returns your temporary security credentials.
- Package the temporary security credentials in an instance of the `SessionAWSCredentials` object. You use this object to provide the temporary security credentials to your Amazon S3 client.
- Create an instance of the `AmazonS3Client` class by passing the temporary security credentials. You use this client to send requests to Amazon S3. If you send requests using expired credentials, Amazon S3 returns an error.

Example

The following C# example lists the keys in the specified bucket. In the example, you obtain temporary security credentials for a two-hour session for your federated user (User1), and use the credentials to send authenticated requests to Amazon S3.

- For this exercise, you create an IAM user with minimal permissions. Using the credentials of this IAM user, you request temporary credentials for others. This example lists only the objects in a specific bucket. Create an IAM user with the following policy attached:

```
{  
    "Statement": [  
        {  
            "Action": ["s3>ListBucket",  
                      "sts:GetFederationToken*"  
                ],  
            "Effect": "Allow",  
            "Resource": "*"  
        }  
    ]  
}
```

The policy allows the IAM user to request temporary security credentials and access permission only to list your AWS resources. For more information about how to create an IAM user, see [Creating Your IAM user User and Administrators Group](#) in the *IAM User Guide*.

- Use the IAM user security credentials to test the following example. The example sends authenticated request to Amazon S3 using temporary security credentials. The example specifies the following policy when requesting temporary security credentials for the federated user (User1), which restricts access to listing objects in a specific bucket (YourBucketName). You must update the policy and provide your own existing bucket name.

```
{  
    "Statement": [  
        {  
            "Sid": "1",  
            "Action": ["s3>ListBucket"],  
            "Effect": "Allow",  
            "Resource": "arn:aws:s3:::YourBucketName"  
        }  
    ]  
}
```

- **Example**

Update the following sample and provide the bucket name that you specified in the preceding federated user access policy. For instructions on how to create and test a working example, see [Running the Amazon S3 .NET Code Examples](#).

```
using Amazon;
using Amazon.Runtime;
using Amazon.S3;
using Amazon.S3.Model;
using Amazon.SecurityToken;
using Amazon.SecurityToken.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class TempFederatedCredentialsTest
    {
        private const string bucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        {
            ListObjectsAsync().Wait();
        }

        private static async Task ListObjectsAsync()
        {
            try
            {
                Console.WriteLine("Listing objects stored in a bucket");
                // Credentials use the default AWS SDK for .NET credential search
chain.
                // On local development machines, this is your default profile.
                SessionAWSCredentials tempCredentials =
                    await GetTemporaryFederatedCredentialsAsync();

                // Create a client by providing temporary security credentials.
            }
        }
    }
}
```

```
        using (client = new AmazonS3Client(bucketRegion))
        {
            ListObjectsRequest listObjectRequest = new
ListObjectsRequest();
            listObjectRequest.BucketName = bucketName;

            ListObjectsResponse response = await
client.ListObjectsAsync(listObjectRequest);
            List<S3Object> objects = response.S3Objects;
            Console.WriteLine("Object count = {0}", objects.Count);

            Console.WriteLine("Press any key to continue...");
            Console.ReadKey();
        }
    }
    catch (AmazonS3Exception e)
    {
        Console.WriteLine("Error encountered ***. Message:'{0}' when
writing an object", e.Message);
    }
    catch (Exception e)
    {
        Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
    }
}

private static async Task<SessionAWSCredentials>
GetTemporaryFederatedCredentialsAsync()
{
    AmazonSecurityTokenServiceConfig config = new
AmazonSecurityTokenServiceConfig();
    AmazonSecurityTokenServiceClient stsClient =
        new AmazonSecurityTokenServiceClient(
            config);

    GetFederationTokenRequest federationTokenRequest =
        new GetFederationTokenRequest();
    federationTokenRequest.DurationSeconds = 7200;
    federationTokenRequest.Name = "User1";
    federationTokenRequest.Policy = @"{"
        ""Statement"": [
            {

```

```
        """Sid"":""Stmt1311212314284""",
        """Action""":[""s3>ListBucket"""],
        """Effect"":""Allow"",
        """Resource""":""arn:aws:s3:::" + bucketName + @"""
    }
]
}
";
;

GetFederationTokenResponse federationTokenResponse =
    await
stsClient.GetFederationTokenAsync(federationTokenRequest);
Credentials credentials = federationTokenResponse.Credentials;

SessionAWSCredentials sessionCredentials =
    new SessionAWSCredentials(credentials.AccessKeyId,
                               credentials.SecretAccessKey,
                               credentials.SessionToken);
return sessionCredentials;
}
}
}
```

PHP

This topic explains how to use classes from version 3 of the AWS SDK for PHP to request temporary security credentials for federated users and applications and use them to access resources stored in Amazon S3. It assumes that you are already following the instructions for [Using the AWS SDK for PHP and Running PHP Examples](#) and have the AWS SDK for PHP properly installed.

You can provide temporary security credentials to your federated users and applications so they can send authenticated requests to access your AWS resources. When requesting these temporary credentials, you must provide a user name and an IAM policy that describes the resource permissions that you want to grant. These credentials expire when the session duration expires. By default, the session duration is one hour. You can explicitly set a different value for the duration when requesting the temporary security credentials for federated users and applications. For more information about temporary security credentials, see [Temporary Security Credentials](#) in the *IAM User Guide*. For information about providing temporary security credentials to your federated users and applications, see [Making requests](#).

For added security when requesting temporary security credentials for federated users and applications, we recommend using a dedicated IAM user with only the necessary access permissions. The temporary user you create can never get more permissions than the IAM user who requested the temporary security credentials. For information about identity federation, see [AWS Identity and Access Management FAQs](#).

For information about running the PHP examples in this guide, see [Running PHP Examples](#).

Example

The following PHP example lists keys in the specified bucket. In the example, you obtain temporary security credentials for an hour session for your federated user (User1). Then you use the temporary security credentials to send authenticated requests to Amazon S3.

For added security when requesting temporary credentials for others, you use the security credentials of an IAM user who has permissions to request temporary security credentials. To ensure that the IAM user grants only the minimum application-specific permissions to the federated user, you can also limit the access permissions of this IAM user. This example lists only objects in a specific bucket. Create an IAM user with the following policy attached:

```
{  
    "Statement": [  
        {  
            "Action": ["s3>ListBucket",  
                      "sts>GetFederationToken"  
            ],  
            "Effect": "Allow",  
            "Resource": "*"  
        }  
    ]  
}
```

The policy allows the IAM user to request temporary security credentials and access permission only to list your AWS resources. For more information about how to create an IAM user, see [Creating Your First IAM user and Administrators Group](#) in the *IAM User Guide*.

You can now use the IAM user security credentials to test the following example. The example sends an authenticated request to Amazon S3 using temporary security credentials. When requesting temporary security credentials for the federated user (User1), the example specifies the following policy, which restricts access to list objects in a specific bucket. Update the policy with your bucket name.

```
{  
  "Statement": [  
    {  
      "Sid": "1",  
      "Action": ["s3>ListBucket"],  
      "Effect": "Allow",  
      "Resource": "arn:aws:s3:::YourBucketName"  
    }  
  ]  
}
```

In the following example, when specifying the policy resource, replace *YourBucketName* with the name of your bucket.:

```
require 'vendor/autoload.php';  
  
use Aws\Sts\StsClient;  
use Aws\S3\S3Client;  
use Aws\S3\Exception\S3Exception;  
  
$bucket = '*** Your Bucket Name ***';  
  
// In real applications, the following code is part of your trusted code. It has  
// the security credentials that you use to obtain temporary security credentials.  
$sts = new StsClient(  
[  
  'version' => 'latest',  
  'region' => 'us-east-1']  
);  
  
// Fetch the federated credentials.  
$sessionToken = $sts->getFederationToken([  
  'Name'          => 'User1',  
  'DurationSeconds' => '3600',  
  'Policy'         => json_encode([  
    'Statement' => [  
      'Sid'           => 'randomstatementid' . time(),  
      'Action'        => ['s3>ListBucket'],  
      'Effect'        => 'Allow',  
      'Resource'      => 'arn:aws:s3:::' . $bucket  
    ]  
  ])  
]);
```

```
// The following will be part of your less trusted code. You provide temporary  
// security credentials so the code can send authenticated requests to Amazon S3.  
  
$s3 = new S3Client([  
    'region' => 'us-east-1',  
    'version' => 'latest',  
    'credentials' => [  
        'key'      => $sessionToken['Credentials']['AccessKeyId'],  
        'secret'   => $sessionToken['Credentials']['SecretAccessKey'],  
        'token'    => $sessionToken['Credentials']['SessionToken']  
    ]  
]);  
  
try {  
    $result = $s3->listObjects([  
        'Bucket' => $bucket  
    ]);  
} catch (S3Exception $e) {  
    echo $e->getMessage() . PHP_EOL;  
}
```

Ruby

You can provide temporary security credentials for your federated users and applications so that they can send authenticated requests to access your AWS resources. When requesting temporary credentials from the IAM service, you must provide a user name and an IAM policy that describes the resource permissions that you want to grant. By default, the session duration is one hour. However, if you are requesting temporary credentials using IAM user credentials, you can explicitly set a different duration value when requesting the temporary security credentials for federated users and applications. For information about temporary security credentials for your federated users and applications, see [Making requests](#).

Note

For added security when you request temporary security credentials for federated users and applications, you might want to use a dedicated IAM user with only the necessary access permissions. The temporary user you create can never get more permissions than the IAM user who requested the temporary security credentials. For more information, see [AWS Identity and Access Management FAQs](#).

Example

The following Ruby code example allows a federated user with a limited set of permissions to lists keys in the specified bucket.

```
# Prerequisites:  
# - An existing Amazon S3 bucket.  
  
require "aws-sdk-s3"  
require "aws-sdk-iam"  
require "json"  
  
# Checks to see whether a user exists in IAM; otherwise,  
# creates the user.  
#  
# @param iam [Aws::IAM::Client] An initialized IAM client.  
# @param user_name [String] The user's name.  
# @return [Aws::IAM::Types::User] The existing or new user.  
# @example  
#   iam = Aws::IAM::Client.new(region: 'us-west-2')  
#   user = get_user(iam, 'my-user')  
#   exit 1 unless user.user_name  
#   puts "User's name: #{user.user_name}"  
def get_user(iam, user_name)  
    puts "Checking for a user with the name '#{user_name}'..."  
    response = iam.get_user(user_name: user_name)  
    puts "A user with the name '#{user_name}' already exists."  
    return response.user  
# If the user doesn't exist, create them.  
rescue Aws::IAM::Errors::NoSuchEntity  
    puts "A user with the name '#{user_name}' doesn't exist. Creating this user..."  
    response = iam.create_user(user_name: user_name)  
    iam.wait_until(:user_exists, user_name: user_name)  
    puts "Created user with the name '#{user_name}'."  
    return response.user  
rescue StandardError => e  
    puts "Error while accessing or creating the user named '#{user_name}':  
    #{e.message}"  
end  
  
# Gets temporary AWS credentials for an IAM user with the specified permissions.  
#  
# @param sts [Aws::STS::Client] An initialized AWS STS client.  
# @param duration_seconds [Integer] The number of seconds for valid credentials.
```

```
# @param user_name [String] The user's name.
# @param policy [Hash] The access policy.
# @return [Aws::STS::Types::Credentials] AWS credentials for API authentication.
# @example
#   sts = Aws::STS::Client.new(region: 'us-west-2')
#   credentials = get_temporary_credentials(sts, duration_seconds, user_name,
#   {
#     'Version' => '2012-10-17',
#     'Statement' => [
#       'Sid' => 'Stmt1',
#       'Effect' => 'Allow',
#       'Action' => 's3>ListBucket',
#       'Resource' => 'arn:aws:s3:::doc-example-bucket'
#     ]
#   }
# )
# exit 1 unless credentials.access_key_id
# puts "Access key ID: #{credentials.access_key_id}"
def get_temporary_credentials(sts, duration_seconds, user_name, policy)
  response = sts.get_federation_token(
    duration_seconds: duration_seconds,
    name: user_name,
    policy: policy.to_json
  )
  return response.credentials
rescue StandardError => e
  puts "Error while getting federation token: #{e.message}"
end

# Lists the keys and ETags for the objects in an Amazon S3 bucket.
#
# @param s3_client [Aws::S3::Client] An initialized Amazon S3 client.
# @param bucket_name [String] The bucket's name.
# @return [Boolean] true if the objects were listed; otherwise, false.
# @example
#   s3_client = Aws::S3::Client.new(region: 'us-west-2')
#   exit 1 unless list_objects_in_bucket?(s3_client, 'doc-example-bucket')
def list_objects_in_bucket?(s3_client, bucket_name)
  puts "Accessing the contents of the bucket named '#{bucket_name}'..."
  response = s3_client.list_objects_v2(
    bucket: bucket_name,
    max_keys: 50
  )
```

```
if response.count.positive?
    puts "Contents of the bucket named '#{bucket_name}' (first 50 objects):"
    puts "Name => ETag"
    response.contents.each do |obj|
        puts "#{obj.key} => #{obj.etag}"
    end
else
    puts "No objects in the bucket named '#{bucket_name}'."
end
return true
rescue StandardError => e
    puts "Error while accessing the bucket named '#{bucket_name}': #{e.message}"
end

# Full example call:
# Replace us-west-2 with the AWS Region you're using for Amazon S3.
def run_me
    region = "us-west-2"
    user_name = "my-user"
    bucket_name = "doc-example-bucket"

    iam = Aws::IAM::Client.new(region: region)
    user = get_user(iam, user_name)

    exit 1 unless user.user_name

    puts "User's name: #{user.user_name}"
    sts = Aws::STS::Client.new(region: region)
    credentials = get_temporary_credentials(sts, 3600, user_name,
    {
        "Version" => "2012-10-17",
        "Statement" => [
            "Sid" => "Stmt1",
            "Effect" => "Allow",
            "Action" => "s3>ListBucket",
            "Resource" => "arn:aws:s3:::#{bucket_name}"
        ]
    })
)

exit 1 unless credentials.access_key_id

puts "Access key ID: #{credentials.access_key_id}"
s3_client = Aws::S3::Client.new(region: region, credentials: credentials)
```

```
exit 1 unless list_objects_in_bucket?(s3_client, bucket_name)
end

run_me if $PROGRAM_NAME == __FILE__
```

Making requests using the REST API

This section contains information on how to make requests to Amazon S3 endpoints by using the REST API. For a list of Amazon S3 endpoints, see [Regions and Endpoints](#) in the *AWS General Reference*.

Constructing S3 hostnames for REST API requests

Amazon S3 endpoints follow the structure shown below:

s3.*Region*.amazonaws.com

Amazon S3 access points endpoints and dual-stack endpoints also follow the standard structure:

- **Amazon S3 access points** -s3-accesspoint.*Region*.amazonaws.com
- **Dual-stack** - s3.dualstack.*Region*.amazonaws.com

For a complete list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

Virtual hosted-style and path-style requests

When making requests by using the REST API, you can use virtual hosted-style or path-style URIs for the Amazon S3 endpoints. For more information, see [Virtual hosting of buckets](#).

Example Virtual hosted–Style request

Following is an example of a virtual hosted–style request to delete the puppy .jpg file from the bucket named examplebucket in the US West (Oregon) Region. For more information about virtual hosted-style requests, see [Virtual-hosted–style requests](#).

```
DELETE /puppy.jpg HTTP/1.1
Host: examplebucket.s3.us-west-2.amazonaws.com
Date: Mon, 11 Apr 2016 12:00:00 GMT
x-amz-date: Mon, 11 Apr 2016 12:00:00 GMT
Authorization: authorization string
```

Example Path-style request

Following is an example of a path-style version of the same request.

```
DELETE /examplebucket/puppy.jpg HTTP/1.1
Host: s3.us-west-2.amazonaws.com
Date: Mon, 11 Apr 2016 12:00:00 GMT
x-amz-date: Mon, 11 Apr 2016 12:00:00 GMT
Authorization: authorization string
```

Currently, Amazon S3 supports both virtual-hosted–style and path-style URL access in all AWS Regions. However, path-style URLs will be discontinued in the future. For more information, see the following **Important** note.

For more information about path-style requests, see [Path-style requests](#).

Important

Update (September 23, 2020) – To make sure that customers have the time that they need to transition to virtual-hosted–style URLs, we have decided to delay the deprecation of path-style URLs. For more information, see [Amazon S3 Path Deprecation Plan – The Rest of the Story](#) in the [AWS News Blog](#).

Making requests to dual-stack endpoints by using the REST API

When using the REST API, you can directly access a dual-stack endpoint by using a virtual hosted–style or a path style endpoint name (URI). All Amazon S3 dual-stack endpoint names include the

region in the name. Unlike the standard IPv4-only endpoints, both virtual hosted-style and a path-style endpoints use region-specific endpoint names.

Example Virtual hosted-Style dual-stack endpoint request

You can use a virtual hosted-style endpoint in your REST request as shown in the following example that retrieves the puppy.jpg object from the bucket named examplebucket in the US West (Oregon) Region.

```
GET /puppy.jpg HTTP/1.1
Host: examplebucket.s3.dualstack.us-west-2.amazonaws.com
Date: Mon, 11 Apr 2016 12:00:00 GMT
x-amz-date: Mon, 11 Apr 2016 12:00:00 GMT
Authorization: authorization string
```

Example Path-style dual-stack endpoint request

Or you can use a path-style endpoint in your request as shown in the following example.

```
GET /examplebucket/puppy.jpg HTTP/1.1
Host: s3.dualstack.us-west-2.amazonaws.com
Date: Mon, 11 Apr 2016 12:00:00 GMT
x-amz-date: Mon, 11 Apr 2016 12:00:00 GMT
Authorization: authorization string
```

For more information about dual-stack endpoints, see [Using Amazon S3 dual-stack endpoints](#).

For more information about making requests using the REST API, see the topics below.

Topics

- [Virtual hosting of buckets](#)
- [Request redirection and the REST API](#)

Virtual hosting of buckets

Virtual hosting is the practice of serving multiple websites from a single web server. One way to differentiate sites in your Amazon S3 REST API requests is by using the apparent hostname of the Request-URI instead of just the path name part of the URI. An ordinary Amazon S3 REST request specifies a bucket by using the first slash-delimited component of the Request-URI path.

Instead, you can use Amazon S3 virtual hosting to address a bucket in a REST API call by using the HTTP Host header. In practice, Amazon S3 interprets Host as meaning that most buckets are automatically accessible for limited types of requests at `https://bucket-name.s3.region-code.amazonaws.com`. For a complete list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

Virtual hosting also has other benefits. By naming your bucket after your registered domain name and by making that name a DNS alias for Amazon S3, you can completely customize the URL of your Amazon S3 resources, for example, `http://my.bucket-name.com/`. You can also publish to the "root directory" of your bucket's virtual server. This ability can be important because many existing applications search for files in this standard location. For example, `favicon.ico`, `robots.txt`, and `crossdomain.xml` are all expected to be found at the root.

Important

When you're using virtual-hosted-style buckets with SSL, the SSL wildcard certificate matches only buckets that do not contain dots (.). To work around this limitation, use HTTP or write your own certificate-verification logic. For more information, see [Amazon S3 Path Deprecation Plan](#) on the *AWS News Blog*.

Path-style requests

Currently, Amazon S3 supports both virtual-hosted-style and path-style URL access in all AWS Regions. However, path-style URLs will be discontinued in the future. For more information, see the following **Important** note.

In Amazon S3, path-style URLs use the following format:

```
https://s3.region-code.amazonaws.com/bucket-name/key-name
```

For example, if you create a bucket named DOC-EXAMPLE-BUCKET1 in the US West (Oregon) Region, and you want to access the puppy.jpg object in that bucket, you can use the following path-style URL:

```
https://s3.us-west-2.amazonaws.com/DOC-EXAMPLE-BUCKET1/puppy.jpg
```

Important

Update (September 23, 2020) – To make sure that customers have the time that they need to transition to virtual-hosted-style URLs, we have decided to delay the deprecation of path-style URLs. For more information, see [Amazon S3 Path Deprecation Plan – The Rest of the Story](#) in the *AWS News Blog*.

Warning

When hosting website content that will be accessed from a web browser, avoid using path-style URLs, which might interfere with the browser same origin security model. To host website content, we recommend that you use either S3 website endpoints or a CloudFront distribution. For more information, see [Website endpoints](#) and [Deploy a React-based single-page application to Amazon S3 and CloudFront](#) in the *AWS Perspective Guidance Patterns*.

Virtual-hosted-style requests

In a virtual-hosted-style URI, the bucket name is part of the domain name in the URL.

Amazon S3 virtual-hosted-style URLs use the following format:

```
https://bucket-name.s3.region-code.amazonaws.com/key-name
```

In this example, DOC-EXAMPLE-BUCKET1 is the bucket name, US West (Oregon) is the Region, and puppy.png is the key name:

<https://DOC-EXAMPLE-BUCKET1.s3.us-west-2.amazonaws.com/puppy.png>

HTTP Host header bucket specification

As long as your GET request does not use the SSL endpoint, you can specify the bucket for the request by using the HTTP Host header. The Host header in a REST request is interpreted as follows:

- If the Host header is omitted or its value is `s3.region-code.amazonaws.com`, the bucket for the request will be the first slash-delimited component of the Request-URI, and the key for the request will be the rest of the Request-URI. This is the ordinary method, as illustrated by the first and second examples in this section. Omitting the Host header is valid only for HTTP 1.0 requests.
- Otherwise, if the value of the Host header ends in `.s3.region-code.amazonaws.com`, the bucket name is the leading component of the Host header's value up to `.s3.region-code.amazonaws.com`. The key for the request is the Request-URI. This interpretation exposes buckets as subdomains of `.s3.region-code.amazonaws.com`, as illustrated by the third and fourth examples in this section.
- Otherwise, the bucket for the request is the lowercase value of the Host header, and the key for the request is the Request-URI. This interpretation is useful when you have registered the same DNS name as your bucket name and have configured that name to be a canonical name (CNAME) alias for Amazon S3. The procedure for registering domain names and configuring CNAME DNS records is beyond the scope of this guide, but the result is illustrated by the final example in this section.

Examples

This section provides example URLs and requests.

Example – Path-style URLs and requests

This example uses the following:

- Bucket Name - `example.com`
- Region - US East (N. Virginia)
- Key Name - `homepage.html`

The URL is as follows:

```
http://s3.us-east-1.amazonaws.com/example.com/homepage.html
```

The request is as follows:

```
GET /example.com/homepage.html HTTP/1.1  
Host: s3.us-east-1.amazonaws.com
```

The request with HTTP 1.0 and omitting the Host header is as follows:

```
GET /example.com/homepage.html HTTP/1.0
```

For information about DNS-compatible names, see [Limitations](#). For more information about keys, see [Keys](#).

Example – Virtual-hosted-style URLs and requests

This example uses the following:

- **Bucket name** - DOC-EXAMPLE-BUCKET1
- **Region** - Europe (Ireland)
- **Key name** - homepage.html

The URL is as follows:

```
http://DOC-EXAMPLE-BUCKET1.s3.eu-west-1.amazonaws.com/homepage.html
```

The request is as follows:

```
GET /homepage.html HTTP/1.1  
Host: DOC-EXAMPLE-BUCKET1.s3.eu-west-1.amazonaws.com
```

Example – CNAME alias method

To use this method, you must configure your DNS name as a CNAME alias for *bucket-name*.s3.us-east-1.amazonaws.com. For more information, see [Customizing Amazon S3 URLs with CNAME records](#).

This example uses the following:

- Bucket Name - example.com
- Key name - homepage.html

The URL is as follows:

```
http://www.example.com/homepage.html
```

The example is as follows:

```
GET /homepage.html HTTP/1.1  
Host: www.example.com
```

Customizing Amazon S3 URLs with CNAME records

Depending on your needs, you might not want s3.*region-code*.amazonaws.com to appear on your website or service. For example, if you're hosting website images on Amazon S3, you might prefer http://images.example.com/ instead of http://images.example.com.s3.us-east-1.amazonaws.com/. Any bucket with a DNS-compatible name can be referenced as follows: http://*BucketName*.s3.*Region*.amazonaws.com/[*Filename*], for example, http://images.example.com.s3.us-east-1.amazonaws.com/mydog.jpg. By using CNAME, you can map images.example.com to an Amazon S3 hostname so that the previous URL could become http://images.example.com/mydog.jpg.

Your bucket name must be the same as the CNAME. For example, if you create a CNAME to map images.example.com to images.example.com.s3.us-east-1.amazonaws.com, both http://images.example.com/filename and http://images.example.com.s3.us-east-1.amazonaws.com/filename will be the same.

The CNAME DNS record should alias your domain name to the appropriate virtual hosted-style hostname. For example, if your bucket name and domain name are images.example.com and your bucket is in the US East (N. Virginia) Region, the CNAME record should alias to images.example.com.s3.us-east-1.amazonaws.com.

```
images.example.com CNAME      images.example.com.s3.us-east-1.amazonaws.com.
```

Amazon S3 uses the hostname to determine the bucket name. So the CNAME and the bucket name must be the same. For example, suppose that you have configured www.example.com as

a CNAME for `www.example.com.s3.us-east-1.amazonaws.com`. When you access `http://www.example.com`, Amazon S3 receives a request similar to the following:

Example

```
GET / HTTP/1.1
Host: www.example.com
Date: date
Authorization: signatureValue
```

Amazon S3 sees only the original hostname `www.example.com` and is unaware of the CNAME mapping used to resolve the request.

You can use any Amazon S3 endpoint in a CNAME alias. For example, `s3.ap-southeast-1.amazonaws.com` can be used in CNAME aliases. For more information about endpoints, see [Request Endpoints](#). To create a static website by using a custom domain, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Important

When using custom URLs with CNAMEs, you will need to ensure a matching bucket exists for any CNAME or alias record you configure. For example, if you create DNS entries for `www.example.com` and `login.example.com` to publish web content using S3, you will need to create both buckets `www.example.com` and `login.example.com`.

When a CNAME or alias records is configured pointing to an S3 endpoint without a matching bucket, any AWS user can create that bucket and publish content under the configured alias, even if ownership is not the same.

For the same reason, we recommend that you change or remove the corresponding CNAME or alias when deleting a bucket.

How to associate a hostname with an Amazon S3 bucket

To associate a hostname with an Amazon S3 bucket by using a CNAME alias

1. Select a hostname that belongs to a domain that you control.

This example uses the `images` subdomain of the `example.com` domain.

2. Create a bucket that matches the hostname.

In this example, the host and bucket names are `images.example.com`. The bucket name must *exactly* match the hostname.

3. Create a CNAME DNS record that defines the hostname as an alias for the Amazon S3 bucket.

For example:

```
images.example.com CNAME images.example.com.s3.us-west-2.amazonaws.com
```

 **Important**

For request-routing reasons, the CNAME DNS record must be defined exactly as shown in the preceding example. Otherwise, it might appear to operate correctly, but it will eventually result in unpredictable behavior.

The procedure for configuring CNAME DNS records depends on your DNS server or DNS provider. For specific information, see your server documentation or contact your provider.

Limitations

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

Backward compatibility

The following sections cover various aspects of Amazon S3 backward compatibility that relate to path-style and virtual-hosted-style URL requests.

Legacy endpoints

Some Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, review the following information. For a complete list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

⚠ Important

Although you might see legacy endpoints in your logs, we recommend that you always use the standard endpoint syntax to access your buckets.

Amazon S3 virtual-hosted-style URLs use the following format:

```
https://bucket-name.s3.region-code.amazonaws.com/key-name
```

In Amazon S3, path-style URLs use the following format:

```
https://s3.region-code.amazonaws.com/bucket-name/key-name
```

s3-Region

Some older Amazon S3 Regions support endpoints that contain a dash (-) between s3 and the Region code (for example, s3-us-west-2), instead of a dot (for example, s3.us-west-2). If your bucket is in one of these Regions, you might see the following endpoint format in your server access logs or CloudTrail logs:

```
https://bucket-name.s3-region-code.amazonaws.com
```

In this example, the bucket name is DOC-EXAMPLE-BUCKET1 and the Region is US West (Oregon):

```
https://DOC-EXAMPLE-BUCKET1.s3-us-west-2.amazonaws.com
```

Legacy global endpoint

For some Regions, you can use the legacy global endpoint to construct requests that do not specify a Region-specific endpoint. The legacy global endpoint point is as follows:

```
bucket-name.s3.amazonaws.com
```

In your server access logs or CloudTrail logs, you might see requests that use the legacy global endpoint. In this example, the bucket name is DOC-EXAMPLE-BUCKET1 and the legacy global endpoint is:

```
https://DOC-EXAMPLE-BUCKET1.s3.amazonaws.com
```

Virtual-hosted-style requests for US East (N. Virginia)

Requests made with the legacy global endpoint go to the US East (N. Virginia) Region by default. Therefore, the legacy global endpoint is sometimes used in place of the Regional endpoint for US East (N. Virginia). If you create a bucket in US East (N. Virginia) and use the global endpoint, Amazon S3 routes your request to this Region by default.

Virtual-hosted-style requests for other Regions

The legacy global endpoint is also used for virtual-hosted-style requests in other supported Regions. If you create a bucket in a Region that was launched before March 20, 2019, and use the legacy global endpoint, Amazon S3 updates the DNS record to reroute the request to the correct location, which might take time. In the meantime, the default rule applies, and your virtual-hosted-style request goes to the US East (N. Virginia) Region. Amazon S3 then redirects it with an HTTP 307 Temporary Redirect to the correct Region.

For S3 buckets in Regions launched after March 20, 2019, the DNS server doesn't route your request directly to the AWS Region where your bucket resides. It returns an HTTP 400 Bad Request error instead. For more information, see [Making requests](#).

Path-style requests

For the US East (N. Virginia) Region, you can use the legacy global endpoint for path-style requests.

For all other Regions, the path-style syntax requires that you use the Region-specific endpoint when attempting to access a bucket. If you try to access a bucket with the legacy global endpoint or another endpoint that is different than the one for the Region where the bucket resides, you receive an HTTP response code 307 Temporary Redirect error and a message that indicates the correct URI for your resource. For example, if you use `https://s3.amazonaws.com/bucket-name` for a bucket that was created in the US West (Oregon) Region, you will receive an HTTP 307 Temporary Redirect error.

Request redirection and the REST API

Topics

- [Redirects and HTTP user-agents](#)
- [Redirects and 100-Continue](#)
- [Redirect example](#)

This section describes how to handle HTTP redirects by using the Amazon S3 REST API. For general information about Amazon S3 redirects, see [Making requests](#) in the Amazon Simple Storage Service API Reference.

Redirects and HTTP user-agents

Programs that use the Amazon S3 REST API should handle redirects either at the application layer or the HTTP layer. Many HTTP client libraries and user agents can be configured to correctly handle redirects automatically; however, many others have incorrect or incomplete redirect implementations.

Before you rely on a library to fulfill the redirect requirement, test the following cases:

- Verify all HTTP request headers are correctly included in the redirected request (the second request after receiving a redirect) including HTTP standards such as Authorization and Date.
- Verify non-GET redirects, such as PUT and DELETE, work correctly.
- Verify large PUT requests follow redirects correctly.
- Verify PUT requests follow redirects correctly if the 100-continue response takes a long time to arrive.

HTTP user-agents that strictly conform to RFC 2616 might require explicit confirmation before following a redirect when the HTTP request method is not GET or HEAD. It is generally safe to follow redirects generated by Amazon S3 automatically, as the system will issue redirects only to hosts within the `amazonaws.com` domain and the effect of the redirected request will be the same as that of the original request.

Redirects and 100-Continue

To simplify redirect handling, improve efficiencies, and avoid the costs associated with sending a redirected request body twice, configure your application to use 100-continues for PUT operations. When your application uses 100-continue, it does not send the request body until it receives an acknowledgement. If the message is rejected based on the headers, the body of the message is not sent. For more information about 100-continue, go to [RFC 2616 Section 8.2.3](#)

Note

According to RFC 2616, when using `Expect: Continue` with an unknown HTTP server, you should not wait an indefinite period before sending the request body. This is because

some HTTP servers do not recognize 100-continue. However, Amazon S3 does recognize if your request contains an Expect: Continue and will respond with a provisional 100-continue status or a final status code. Additionally, no redirect error will occur after receiving the provisional 100 continue go-ahead. This will help you avoid receiving a redirect response while you are still writing the request body.

Redirect example

This section provides an example of client-server interaction using HTTP redirects and 100-continue.

Following is a sample PUT to the quotes.s3.amazonaws.com bucket.

```
PUT /nelson.txt HTTP/1.1
Host: quotes.s3.amazonaws.com
Date: Mon, 15 Oct 2007 22:18:46 +0000

Content-Length: 6
Expect: 100-continue
```

Amazon S3 returns the following:

```
HTTP/1.1 307 Temporary Redirect
Location: http://quotes.s3-4c25d83b.amazonaws.com/nelson.txt?rk=8d47490b
Content-Type: application/xml
Transfer-Encoding: chunked
Date: Mon, 15 Oct 2007 22:18:46 GMT

Server: AmazonS3

<?xml version="1.0" encoding="UTF-8"?>
<Error>
  <Code>TemporaryRedirect</Code>
  <Message>Please re-send this request to the
specified temporary endpoint. Continue to use the
original request endpoint for future requests.
</Message>
<Endpoint>quotes.s3-4c25d83b.amazonaws.com</Endpoint>
<Bucket>quotes</Bucket>
```

```
</Error>
```

The client follows the redirect response and issues a new request to the quotes.s3-4c25d83b.amazonaws.com temporary endpoint.

```
PUT /nelson.txt?rk=8d47490b HTTP/1.1
Host: quotes.s3-4c25d83b.amazonaws.com
Date: Mon, 15 Oct 2007 22:18:46 +0000

Developing with Amazon S3 using the AWS CLI

Follow these steps to download and configure AWS Command Line Interface (AWS CLI).

For a list of Amazon S3 AWS CLI commands, see the following pages in the *AWS CLI Command Reference*:

- [s3](#)

- [s3api](#)
- [s3control](#)

Note

Services in AWS, such as Amazon S3, require that you provide credentials when you access them. The service can then determine whether you have permissions to access the resources that it owns. The console requires your password. You can create access keys for your AWS account to access the AWS CLI or API. However, we don't recommend that you access AWS using the credentials for your AWS account. Instead, we recommend that you use AWS Identity and Access Management (IAM). Create an IAM user, add the user to an IAM group with administrative permissions, and then grant administrative permissions to the IAM user that you created. You can then access AWS using a special URL and the credentials of that IAM user. For instructions, go to [Creating Your First IAM user and Administrators Group](#) in the *IAM User Guide*.

To set up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the *AWS Command Line Interface User Guide*:
 - [Getting Set Up with the AWS Command Line Interface](#)
 - [Configuring the AWS Command Line Interface](#)
2. Add a named profile for the administrator user in the AWS CLI config file. You use this profile when executing the AWS CLI commands. For more information, see [Named profiles for the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

```
[adminuser]
aws_access_key_id = adminuser access key ID
aws_secret_access_key = adminuser secret access key
region = aws-region
```

For a list of available AWS Regions, see [Regions and Endpoints](#) in the *AWS General Reference*.

3. Verify the setup by typing the following commands at the command prompt.
 - Try the help command to verify that the AWS CLI is installed on your computer:

```
aws help
```

- Run an S3 command using the `adminuser` credentials that you just created. To do this, add the `--profile` parameter to your command to specify the profile name. In this example, the `ls` command lists buckets in your account. The AWS CLI uses the `adminuser` credentials to authenticate the request.

```
aws s3 ls --profile adminuser
```

Developing with Amazon S3 using the AWS SDKs, and explorers

You can use the AWS SDKs when developing applications with Amazon S3. The AWS SDKs simplify your programming tasks by wrapping the underlying REST API. The AWS Mobile SDKs and the AWS Amplify JavaScript library are also available for building connected mobile and web applications using AWS.

This section provides an overview of using AWS SDKs for developing Amazon S3 applications. This section also describes how you can test the AWS SDK code examples provided in this guide.

Topics

- [Using this service with an AWS SDK](#)
- [Specifying the Signature Version in Request Authentication](#)
- [Using the AWS SDK for Java](#)
- [Using the AWS SDK for .NET](#)
- [Using the AWS SDK for PHP and Running PHP Examples](#)
- [Using the AWS SDK for Ruby - Version 3](#)
- [Using the AWS SDK for Python \(Boto\)](#)
- [Using the AWS Mobile SDKs for iOS and Android](#)
- [Using the AWS Amplify JavaScript Library](#)
- [Using the AWS SDK for JavaScript](#)

In addition to the AWS SDKs, AWS Explorers are available for Visual Studio and Eclipse for Java IDE. In this case, the SDKs and the explorers are available bundled together as AWS Toolkits.

You can also use the AWS Command Line Interface (AWS CLI) to manage Amazon S3 buckets and objects.

AWS Toolkit for Eclipse

The AWS Toolkit for Eclipse includes both the AWS SDK for Java and AWS Explorer for Eclipse. The AWS Explorer for Eclipse is an open source plugin for Eclipse for Java IDE that makes it easier for developers to develop, debug, and deploy Java applications using AWS. The easy-to-use GUI enables you to access and administer your AWS infrastructure including Amazon S3. You can perform common operations such as managing your buckets and objects and setting IAM policies, while developing applications, all from within the context of Eclipse for Java IDE. For set up instructions, see [Set up the Toolkit](#). For examples of using the explorer, see [How to Access AWS Explorer](#).

AWS Toolkit for Visual Studio

AWS Explorer for Visual Studio is an extension for Microsoft Visual Studio that makes it easier for developers to develop, debug, and deploy .NET applications using Amazon Web Services. The easy-to-use GUI enables you to access and administer your AWS infrastructure including Amazon S3. You can perform common operations such as managing your buckets and objects or setting IAM policies, while developing applications, all from within the context of Visual Studio. For setup instructions, go to [Setting Up the AWS Toolkit for Visual Studio](#). For examples of using Amazon S3 using the explorer, see [Using Amazon S3 from AWS Explorer](#).

AWS SDKs

You can download only the SDKs. For information about downloading the SDK libraries, see [Sample Code Libraries](#).

AWS CLI

The AWS CLI is a unified tool to manage your AWS services, including Amazon S3. For information about downloading the AWS CLI, see [AWS Command Line Interface](#).

Using this service with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples
AWS SDK for SAP ABAP	AWS SDK for SAP ABAP code examples
AWS SDK for Swift	AWS SDK for Swift code examples

For examples specific to this service, see [Code examples for Amazon S3 using AWS SDKs](#).

Example availability

Can't find what you need? Request a code example by using the **Provide feedback** link at the bottom of this page.

Specifying the Signature Version in Request Authentication

Amazon S3 supports only AWS Signature Version 4 in most AWS Regions. In some of the older AWS Regions, Amazon S3 supports both Signature Version 4 and Signature Version 2. However, Signature Version 2 is being turned off (deprecated). For more information about the end of

support for Signature Version 2, see [AWS Signature Version 2 Turned Off \(Deprecated\) for Amazon S3](#).

For a list of all the Amazon S3 Regions and the signature versions they support, see [Regions and Endpoints](#) in the *AWS General Reference*.

For all AWS Regions, AWS SDKs use Signature Version 4 by default to authenticate requests. When using AWS SDKs that were released before May 2016, you might be required to request Signature Version 4, as shown in the following table.

SDK	Requesting Signature Version 4 for Request Authentication
AWS CLI	<p>For the default profile, run the following command:</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><pre>\$ aws configure set default.s3.signature_version s3v4</pre></div> <p>For a custom profile, run the following command:</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><pre>\$ aws configure set profile.your_profile_name.s3.signature_version s3v4</pre></div>
Java SDK	<p>Add the following in your code:</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><pre>System.setProperty(SDKGlobalConfiguration.ENABLE_S3_SIGV4_SYSTEM_PROPERTY, "true");</pre></div> <p>Or, on the command line, specify the following:</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><pre>-Dcom.amazonaws.services.s3.enableV4</pre></div>
JavaScript SDK	<p>Set the <code>signatureVersion</code> parameter to <code>v4</code> when constructing the client:</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><pre>var s3 = new AWS.S3({signatureVersion: 'v4'});</pre></div>
PHP SDK	<p>Set the <code>signature</code> parameter to <code>v4</code> when constructing the Amazon S3 service client for PHP SDK v2:</p>

SDK	Requesting Signature Version 4 for Request Authentication
	<pre><?php \$client = S3Client::factory(['region' => 'YOUR-REGION', 'version' => 'latest', 'signature' => 'v4']);</pre> <p>When using the PHP SDK v3, set the <code>signature_version</code> parameter to <code>v4</code> during construction of the Amazon S3 service client:</p> <pre><?php \$s3 = new Aws\S3\S3Client(['version' => '2006-03-01', 'region' => 'YOUR-REGION', 'signature_version' => 'v4']);</pre>
Python-Boto SDK	Specify the following in the boto default config file:
Ruby SDK	<p>Ruby SDK - Version 1: Set the <code>:s3_signature_version</code> parameter to <code>:v4</code> when constructing the client:</p> <pre>s3 = AWS::S3::Client.new(:s3_signature_version => :v4)</pre> <p>Ruby SDK - Version 3: Set the <code>signature_version</code> parameter to <code>v4</code> when constructing the client:</p> <pre>s3 = Aws::S3::Client.new(signature_version: 'v4')</pre>

SDK	Requesting Signature Version 4 for Request Authentication
.NET SDK	<p>Add the following to the code before creating the Amazon S3 client:</p> <pre>AWSConfigsS3.UseSignatureVersion4 = true;</pre> <p>Or, add the following to the config file:</p> <pre><appSettings> <add key="AWS.S3.UseSignatureVersion4" value="true" /> </appSettings></pre>

AWS Signature Version 2 Turned Off (Deprecated) for Amazon S3

Signature Version 2 is being turned off (deprecated) in Amazon S3. Amazon S3 will then only accept API requests that are signed using Signature Version 4.

This section provides answers to common questions regarding the end of support for Signature Version 2.

What is Signature Version 2/4, and What Does It Mean to Sign Requests?

The Signature Version 2 or Signature Version 4 signing process is used to authenticate your Amazon S3 API requests. Signing requests enables Amazon S3 to identify who is sending the request and protects your requests from bad actors.

For more information about signing AWS requests, see [Signing AWS API Requests](#) in the AWS General Reference.

What Update Are You Making?

We currently support Amazon S3 API requests that are signed using Signature Version 2 and Signature Version 4 processes. After that, Amazon S3 will only accept requests that are signed using Signature Version 4.

For more information about signing AWS requests, see [Changes in Signature Version 4 in the AWS General Reference](#).

Why Are You Making the Update?

Signature Version 4 provides improved security by using a signing key instead of your secret access key. Signature Version 4 is currently supported in all AWS Regions, whereas Signature Version 2 is only supported in Regions that were launched before January 2014. This update allows us to provide a more consistent experience across all Regions.

How Do I Ensure That I'm Using Signature Version 4, and What Updates Do I Need?

The signature version that is used to sign your requests is usually set by the tool or the SDK on the client side. By default, the latest versions of our AWS SDKs use Signature Version 4. For third-party software, contact the appropriate support team for your software to confirm what version you need. If you are sending direct REST calls to Amazon S3, you must modify your application to use the Signature Version 4 signing process.

For information about which version of the AWS SDKs to use when moving to Signature Version 4, see [Moving from Signature Version 2 to Signature Version 4](#).

For information about using Signature Version 4 with the Amazon S3 REST API, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

What Happens if I Don't Make Updates?

Requests signed with Signature Version 2 that are made after that will fail to authenticate with Amazon S3. Requesters will see errors stating that the request must be signed with Signature Version 4.

Should I Make Changes Even if I'm Using a Presigned URL That Requires Me to Sign for More than 7 Days?

If you are using a presigned URL that requires you to sign for more than 7 days, no action is currently needed. You can continue to use AWS Signature Version 2 to sign and authenticate the presigned URL. We will follow up and provide more details on how to migrate to Signature Version 4 for a presigned URL scenario.

More Info

- For more information about using Signature Version 4, see [Signing AWS API Requests](#).

- View the list of changes between Signature Version 2 and Signature Version 4 in [Changes in Signature Version 4](#).
- View the post [AWS Signature Version 4 to replace AWS Signature Version 2 for signing Amazon S3 API requests](#) in the AWS forums.
- If you have any questions or concerns, contact [AWS Support](#).

Moving from Signature Version 2 to Signature Version 4

If you currently use Signature Version 2 for Amazon S3 API request authentication, you should move to using Signature Version 4. Support is ending for Signature Version 2, as described in [AWS Signature Version 2 Turned Off \(Deprecated\) for Amazon S3](#).

For information about using Signature Version 4 with the Amazon S3 REST API, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

The following table lists the SDKs with the necessary minimum version to use Signature Version 4 (SigV4). If you are using presigned URLs with the AWS Java, JavaScript (Node.js), or Python (Boto/CLI) SDKs, you must set the correct AWS Region and set Signature Version 4 in the client configuration. For information about setting SigV4 in the client configuration, see [Specifying the Signature Version in Request Authentication](#).

If you use this SDK/Product	Upgrade to this SDK version	Code change needed to the client to use Sigv4?	Link to SDK documentation
AWS SDK for Java v1	Upgrade to Java 1.11.201+ or v2.	Yes	Specifying the Signature Version in Request Authentication
AWS SDK for Java v2	No SDK upgrade is needed.	No	AWS SDK for Java

If you use this SDK/Product	Upgrade to this SDK version	Code change needed to the client to use Sigv4?	Link to SDK documentation
AWS SDK for .NET v1	Upgrade to 3.1.10 or later.	Yes	AWS SDK for .NET
AWS SDK for .NET v2	Upgrade to 3.1.10 or later.	No	AWS SDK for .NET v2
AWS SDK for .NET v3	Upgrade to 3.3.0.0 or later.	Yes	AWS SDK for .NET v3
AWS SDK for JavaScript v1	Upgrade to 2.68.0 or later.	Yes	AWS SDK for JavaScript
AWS SDK for JavaScript v2	Upgrade to 2.68.0 or later.	Yes	AWS SDK for JavaScript
AWS SDK for JavaScript v3	No action is currently needed. Upgrade to major version V3 in Q3 2019.	No	AWS SDK for JavaScript

If you use this SDK/Product	Upgrade to this SDK version	Code change needed to the client to use Sigv4?	Link to SDK documentation
AWS SDK for PHP v1	Recommend to upgrade to the most recent version of PHP or, at least to v2.7.4 with the signature parameter set to v4 in the S3 client's configuration.	Yes	AWS SDK for PHP
AWS SDK for PHP v2	Recommend to upgrade to the most recent version of PHP or, at least to v2.7.4 with the signature parameter set to v4 in the S3 client's configuration.	No	AWS SDK for PHP

If you use this SDK/Product	Upgrade to this SDK version	Code change needed to the client to use Sigv4?	Link to SDK documentation
AWS SDK for PHP v3	No SDK upgrade is needed.	No	AWS SDK for PHP
Boto2	Upgrade to Boto2 v2.49.0.	Yes	Boto 2 Upgrade
Boto3	Upgrade to 1.5.71 (Botocore), 1.4.6 (Boto3).	Yes	Boto 3 - AWS SDK for Python
AWS CLI	Upgrade to 1.11.108.	Yes	AWS Command Line Interface
AWS CLI v2 (preview)	No SDK upgrade is needed.	No	AWS Command Line Interface version 2
AWS SDK for Ruby v1	Upgrade to Ruby V3.	Yes	Ruby V3 for AWS
AWS SDK for Ruby v2	Upgrade to Ruby V3.	Yes	Ruby V3 for AWS
AWS SDK for Ruby v3	No SDK upgrade is needed.	No	Ruby V3 for AWS
Go	No SDK upgrade is needed.	No	AWS SDK for Go

If you use this SDK/ Product	Upgrade to this SDK version	Code change needed to the client to use Sigv4?	Link to SDK documentation
C++	No SDK upgrade is needed.	No	AWS SDK for C++

AWS Tools for Windows PowerShell or AWS Tools for PowerShell Core

If you are using module versions *earlier* than 3.3.0.0, you must upgrade to 3.3.0.0.

To get the version information, use the Get-Module cmdlet:

```
Get-Module -Name AWSPowerShell  
Get-Module -Name AWSPowerShell.NetCore
```

To update the 3.3.0.0 version, use the Update-Module cmdlet:

```
Update-Module -Name AWSPowerShell  
Update-Module -Name AWSPowerShell.NetCore
```

You can use presigned URLs that are valid for more than 7 days that you will send Signature Version 2 traffic on.

Using the AWS SDK for Java

The AWS SDK for Java provides an API for the Amazon S3 bucket and object operations. For object operations, in addition to providing the API to upload objects in a single operation, the SDK provides an API to upload large objects in parts. For more information, see [Uploading and copying objects using multipart upload](#).

Topics

- [The Java API Organization](#)
- [Testing the Amazon S3 Java Code Examples](#)

The AWS SDK for Java gives you the option of using a high-level or low-level API.

Low-Level API

The low-level APIs correspond to the underlying Amazon S3 REST operations, such as create, update, and delete operations that apply to buckets and objects. When you upload large objects using the low-level multipart upload API, it provides greater control. For example, it lets you pause and resume multipart uploads, vary part sizes during the upload, or begin uploads when you don't know the size of the data in advance. If you don't have these requirements, use the high-level API to upload objects.

High-Level API

For uploading objects, the SDK provides a higher level of abstraction by providing the `TransferManager` class. The high-level API is a simpler API, where in just a few lines of code you can upload files and streams to Amazon S3. You should use this API to upload data unless you need to control the upload as described in the preceding Low-Level API section.

For smaller data size, the `TransferManager` API uploads data in a single operation. However, the `TransferManager` switches to using the multipart upload API when the data size reaches a certain threshold. When possible, the `TransferManager` uses multiple threads to concurrently upload the parts. If a part upload fails, the API retries the failed part upload up to three times. However, these are configurable options using the `TransferManagerConfiguration` class.

Note

When you're using a stream for the source of data, the `TransferManager` class does not do concurrent uploads.

The Java API Organization

The following packages in the AWS SDK for Java provide the API:

- **com.amazonaws.services.s3**—Provides the APIs for creating Amazon S3 clients and working with buckets and objects. For example, it enables you to create buckets, upload objects, get objects, delete objects, and list keys.
- **com.amazonaws.services.s3.transfer**—Provides the high-level API data operations.

This high-level API is designed to simplify transferring objects to and from Amazon S3. It includes the `TransferManager` class, which provides asynchronous methods for working with, querying, and manipulating transfers. It also includes the `TransferManagerConfiguration` class, which you can use to configure the minimum part size for uploading parts and the threshold in bytes of when to use multipart uploads.

- **com.amazonaws.services.s3.model**—Provides the low-level API classes to create requests and process responses. For example, it includes the `GetObjectRequest` class to describe your get object request, the `ListObjectsRequest` class to describe your list keys requests, and the `InitiateMultipartUploadRequest` class to create multipart uploads.

For more information about the AWS SDK for Java API, see [AWS SDK for Java API Reference](#).

Testing the Amazon S3 Java Code Examples

The Java examples in this guide are compatible with the AWS SDK for Java version 1.11.321. For instructions on setting up and running code samples, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

Using the AWS SDK for .NET

The AWS SDK for .NET provides the API for the Amazon S3 bucket and object operations. For object operations, in addition to providing the API to upload objects in a single operation, the SDK provides the API to upload large objects in parts (see [Uploading and copying objects using multipart upload](#)).

Topics

- [The .NET API Organization](#)
- [Running the Amazon S3 .NET Code Examples](#)

The AWS SDK for .NET gives you the option of using a high-level or low-level API.

Low-Level API

The low-level APIs correspond to the underlying Amazon S3 REST operations, including the create, update, and delete operations that apply to buckets and objects. When you upload large objects using the low-level multipart upload API (see [Uploading and copying objects using multipart upload](#)), it provides greater control. For example, it lets you pause and resume multipart uploads, vary part sizes during the upload, or begin uploads when you don't know the size of the data in advance. If you do not have these requirements, use the high-level API for uploading objects.

High-Level API

For uploading objects, the SDK provides a higher level of abstraction by providing the `TransferUtility` class. The high-level API is a simpler API, where in just a few lines of code, you can upload files and streams to Amazon S3. You should use this API to upload data unless you need to control the upload as described in the preceding Low-Level API section.

For smaller data size, the `TransferUtility` API uploads data in a single operation. However, the `TransferUtility` switches to using the multipart upload API when the data size reaches a certain threshold. By default, it uses multiple threads to concurrently upload the parts. If a part upload fails, the API retries the failed part upload up to three times. However, these are configurable options.

Note

When you're using a stream for the source of data, the `TransferUtility` class does not do concurrent uploads.

The .NET API Organization

When writing Amazon S3 applications using the AWS SDK for .NET, you use the `AWSSDK.dll`. The following namespaces in this assembly provide the multipart upload API:

- **Amazon.S3.Transfer**—Provides the high-level API to upload your data in parts.

It includes the `TransferUtility` class that enables you to specify a file, directory, or stream for uploading your data. It also includes the `TransferUtilityUploadRequest` and `TransferUtilityUploadDirectoryRequest` classes to configure advanced settings, such as the number of concurrent threads, part size, object metadata, the storage class (STANDARD, REDUCED_REDUNDANCY), and object access control list (ACL).

- **Amazon.S3**—Provides the implementation for the low-level APIs.

It provides methods that correspond to the Amazon S3 REST multipart upload API (see [Using the REST API](#)).

- **Amazon.S3.Model**—Provides the low-level API classes to create requests and process responses. For example, it provides the `InitiateMultipartUploadRequest` and `InitiateMultipartUploadResponse` classes you can use when initiating a multipart upload, and the `UploadPartRequest` and `UploadPartResponse` classes when uploading parts.
- **Amazon.S3.Encryption**— Provides `AmazonS3EncryptionClient`.
- **Amazon.S3.Util**— Provides various utility classes such as `AmazonS3Util` and `BucketRegionDetector`.

For more information about the AWS SDK for .NET API, see [AWS SDK for .NET Version 3 API Reference](#).

Running the Amazon S3 .NET Code Examples

The .NET code examples in this guide are compatible with the AWS SDK for .NET version 3.0. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

Using the AWS SDK for PHP and Running PHP Examples

The AWS SDK for PHP provides access to the API for Amazon S3 bucket and object operations. The SDK gives you the option of using the service's low-level API or using higher-level abstractions.

The SDK is available at [AWS SDK for PHP](#), which also has instructions for installing and getting started with the SDK.

The setup for using the AWS SDK for PHP depends on your environment and how you want to run your application. To set up your environment to run the examples in this documentation, see the [AWS SDK for PHP Getting Started Guide](#).

Topics

- [AWS SDK for PHP Levels](#)
- [Running PHP Examples](#)
- [Related Resources](#)

AWS SDK for PHP Levels

The AWS SDK for PHP gives you the option of using a high-level or low-level API.

Low-Level API

The low-level APIs correspond to the underlying Amazon S3 REST operations, including the create, update, and delete operations on buckets and objects. The low-level APIs provide greater control over these operations. For example, you can batch your requests and run them in parallel. Or, when using the multipart upload API, you can manage the object parts individually. Note that these low-level API calls return a result that includes all of the Amazon S3 response details. For more information about the multipart upload API, see [Uploading and copying objects using multipart upload](#).

High-Level Abstractions

The high-level abstractions are intended to simplify common use cases. For example, for uploading large objects using the low-level API, you call `Aws\S3\S3Client::createMultipartUpload()`, call the `Aws\S3\S3Client::uploadPart()` method to upload the object parts, then call the `Aws\S3\S3Client::completeMultipartUpload()` method to complete the upload. You can use the higher-level `Aws\S3\MultipartUploader` object that simplifies creating a multipart upload instead.

As another example, when enumerating objects in a bucket, you can use the iterators feature of the AWS SDK for PHP to return all of the object keys, regardless of how many objects you have stored in the bucket. If you use the low-level API, the response returns a maximum of 1,000 keys. If a bucket contains more than 1,000 objects, the result is truncated and you have to manage the response and check for truncation.

Running PHP Examples

To set up and use the Amazon S3 samples for version 3 of the AWS SDK for PHP, see [Installation](#) in the AWS SDK for PHP Developer Guide.

- [AWS SDK for PHP Version 3 Code Examples](#)

Using the AWS SDK for Ruby - Version 3

The AWS SDK for Ruby provides an API for Amazon S3 bucket and object operations. For object operations, you can use the API to upload objects in a single operation or upload large objects in parts (see [Uploading an object using multipart upload](#)). However, the API for a single operation upload can also accept large objects and behind the scenes manage the upload in parts for you, thereby reducing the amount of script you need to write.

The Ruby API Organization

When creating Amazon S3 applications using the AWS SDK for Ruby, you must install the SDK for Ruby gem. For more information, see the [AWS SDK for Ruby - Version 3](#). Once installed, you can access the API, including the following key classes:

- **Aws::S3::Resource**—Represents the interface to Amazon S3 for the Ruby SDK and provides methods for creating and enumerating buckets.

The S3 class provides the `#buckets` instance method for accessing existing buckets or creating new ones.

- **Aws::S3::Bucket**—Represents an Amazon S3 bucket.

The Bucket class provides the `#object(key)` and `#objects` methods for accessing the objects in a bucket, as well as methods to delete a bucket and return information about a bucket, like the bucket policy.

- **Aws::S3::Object**—Represents an Amazon S3 object identified by its key.

The Object class provides methods for getting and setting properties of an object, specifying the storage class for storing objects, and setting object permissions using access control lists. The Object class also has methods for deleting, uploading and copying objects. When uploading objects in parts, this class provides options for you to specify the order of parts uploaded and the part size.

For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

Testing the Ruby Script Examples

The easiest way to get started with the Ruby script examples is to install the latest AWS SDK for Ruby gem. For information about installing or updating to the latest gem, go to [AWS SDK for Ruby](#)

- Version 3. The following tasks guide you through the creation and testing of the Ruby script examples assuming that you have installed the AWS SDK for Ruby.

General Process of Creating and Testing Ruby Script Examples

- 1 To access AWS, you must provide a set of credentials for your SDK for Ruby application. For more information, see [Configuring the AWS SDK for Ruby](#).
- 2 Create a new SDK for Ruby script and add the following lines to the top of the script.

```
#!/usr/bin/env ruby

require 'rubygems'
require 'aws-sdk-s3'
```

The first line is the interpreter directive and the two require statements import two required gems into your script.
- 3 Copy the code from the section you are reading to your script.
- 4 Update the code by providing any required data. For example, if uploading a file, provide the file path and the bucket name.
- 5 Run the script. Verify changes to buckets and objects by using the AWS Management Console. For more information about the AWS Management Console, go to <https://aws.amazon.com/console/>.

Ruby Samples

The following links contain samples to help get you started with the SDK for Ruby - Version 3:

- [Creating a bucket](#)
- [Uploading objects](#)

Using the AWS SDK for Python (Boto)

Boto is a Python package that provides interfaces to AWS including Amazon S3. For more information about Boto, go to the [AWS SDK for Python \(Boto\)](#). The getting started link on this page provides step-by-step instructions to get started.

Using the AWS Mobile SDKs for iOS and Android

You can use the AWS Mobile SDKs for [Android](#) and [iOS](#) to quickly and easily integrate robust cloud backends into your existing mobile apps. You can configure and use features like user sign-in, databases, push notifications, and more, without being an AWS expert.

The AWS Mobile SDKs provide easy access to Amazon S3 and many other AWS services. To get started using the AWS Mobile SDKs, see [Getting Started with the AWS Mobile SDKs](#).

More Info

[Using the AWS Amplify JavaScript Library](#)

Using the AWS Amplify JavaScript Library

AWS Amplify is an open source JavaScript library for web and mobile developers who build cloud-enabled applications. AWS Amplify provides customizable UI components and a declarative interface to work with an S3 bucket, along with other high-level categories for AWS services.

To get started using the AWS Amplify JavaScript library, choose one of the following links:

- [Getting Started with the AWS Amplify Library for the Web](#)
- [Getting Started with Amplify](#)

For more information about AWS Amplify, see [AWS Amplify](#) on GitHub.

More Info

[Using the AWS Mobile SDKs for iOS and Android](#)

Using the AWS SDK for JavaScript

The AWS SDK for JavaScript provides a JavaScript API for AWS services. You can use the JavaScript API to build libraries or applications for Node.js or the browser.

For more information about using the AWS SDK for JavaScript for Amazon S3, see below.

- [What is the AWS SDK for JavaScript? \(v2\)](#)
- [AWS SDK for JavaScript - Amazon S3 examples \(v2\)](#)
- [AWS SDK for JavaScript API reference for Amazon S3 \(v2\)](#)

- [AWS SDK for JavaScript - Amazon S3 examples \(v3\)](#)
- [AWS SDK for JavaScript API reference for Amazon S3 \(v3\)](#)

Developing with Amazon S3 using the REST API

The Amazon S3 architecture is designed to be programming language-neutral, using our supported interfaces to store and retrieve objects.

Amazon S3 currently provides a REST interface. With REST, metadata is returned in HTTP headers. Because we only support HTTP requests of up to 4 KB (not including the body), the amount of metadata you can supply is restricted. The REST API is an HTTP interface to Amazon S3. Using REST, you use standard HTTP requests to create, fetch, and delete buckets and objects.

You can use any toolkit that supports HTTP to use the REST API. You can even use a browser to fetch objects, as long as they are anonymously readable.

The REST API uses the standard HTTP headers and status codes, so that standard browsers and toolkits work as expected. In some areas, we have added functionality to HTTP (for example, we added headers to support access control). In these cases, we have done our best to add the new functionality in a way that matched the style of standard HTTP usage.

For more information about sending requests using the REST API, see [Making requests using the REST API](#). For some considerations you should keep in mind when using the REST API, see the topics below.

For more information about the Amazon S3 REST API, see the [Amazon Simple Storage Service API Reference](#).

Topics

- [Request routing](#)

Request routing

Programs that make requests against buckets created using the [CreateBucket](#) API that include a [CreateBucketConfiguration](#) must support redirects. Additionally, some clients that do not respect DNS TTLs might encounter issues.

This section describes routing and DNS issues to consider when designing your service or application for use with Amazon S3.

Request redirection and the REST API

Amazon S3 uses the Domain Name System (DNS) to route requests to facilities that can process them. This system works effectively, but temporary routing errors can occur. If a request arrives at the wrong Amazon S3 location, Amazon S3 responds with a temporary redirect that tells the requester to resend the request to a new endpoint. If a request is incorrectly formed, Amazon S3 uses permanent redirects to provide direction on how to perform the request correctly.

Important

To use this feature, you must have an application that can handle Amazon S3 redirect responses. The only exception is for applications that work exclusively with buckets that were created without <CreateBucketConfiguration>. For more information about location constraints, see [Accessing and listing an Amazon S3 bucket](#).

For all Regions that launched after March 20, 2019, if a request arrives at the wrong Amazon S3 location, Amazon S3 returns an HTTP 400 Bad Request error.

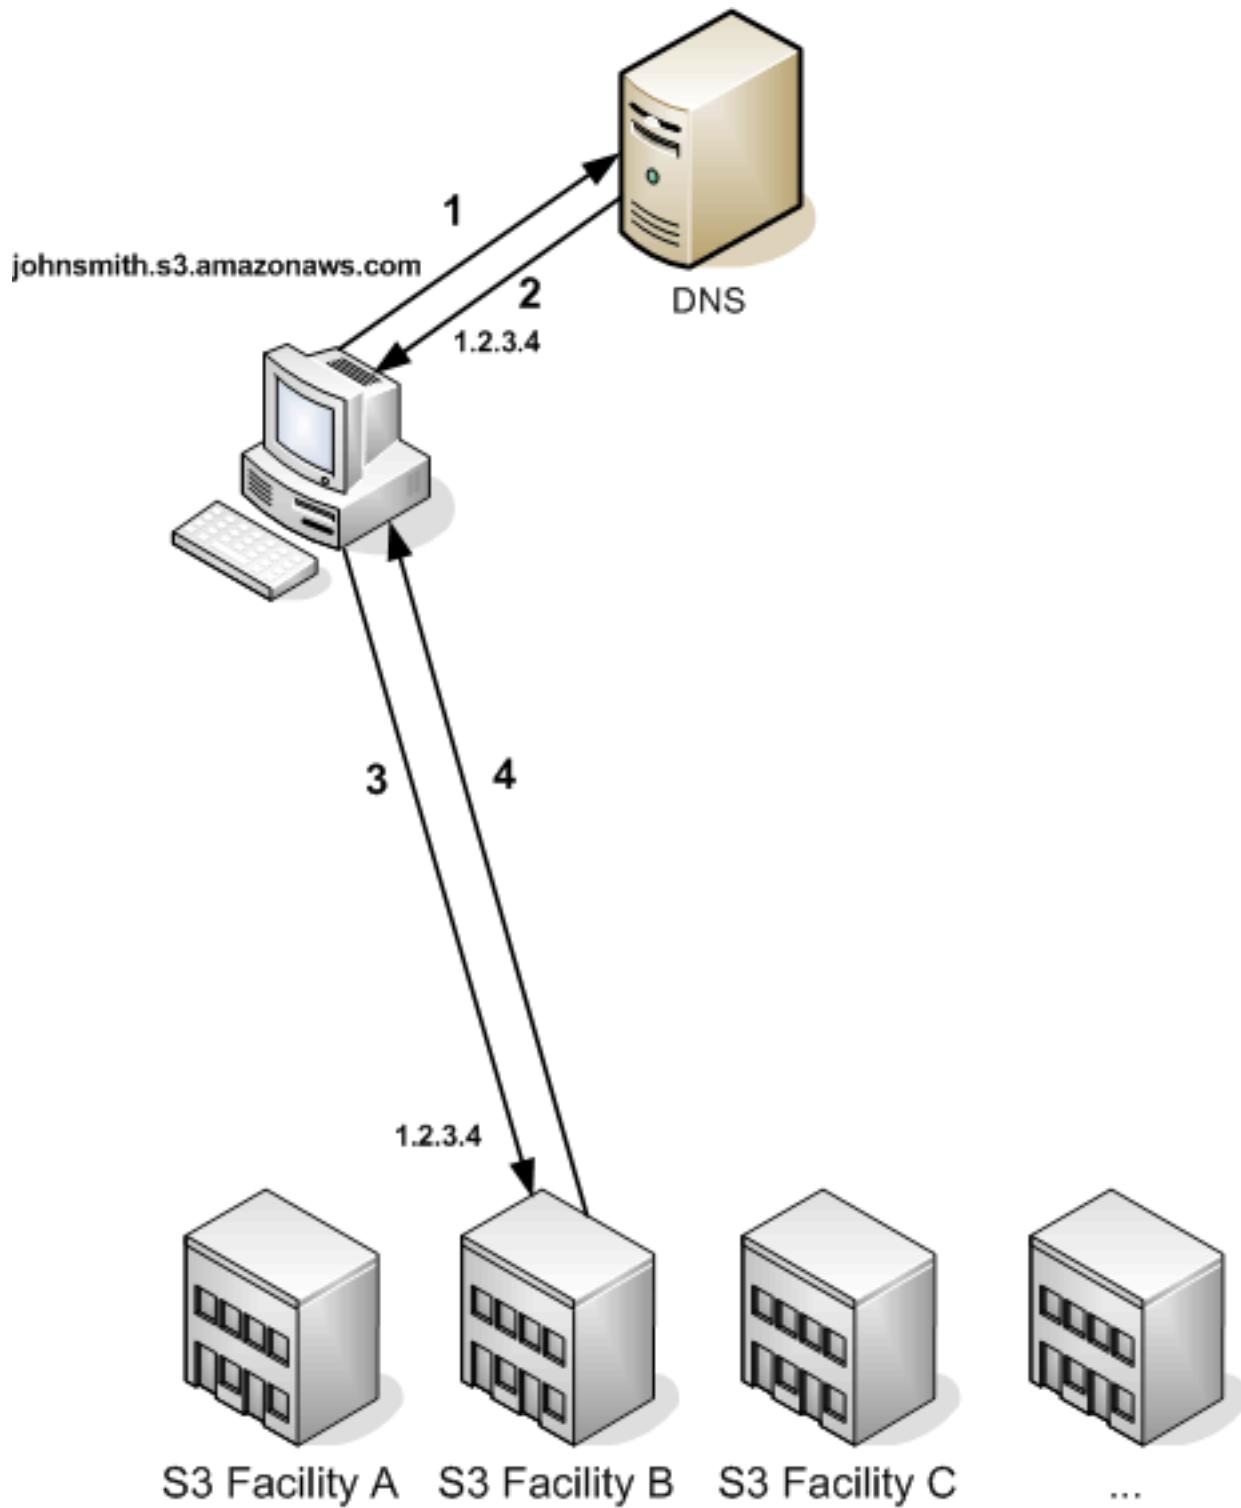

For more information about enabling or disabling an AWS Region, see [AWS Regions and Endpoints](#) in the *AWS General Reference*.

Topics

- [DNS routing](#)
- [Temporary request redirection](#)
- [Permanent request redirection](#)
- [Request redirection examples](#)

DNS routing

DNS routing routes requests to appropriate Amazon S3 facilities. The following figure and procedure show an example of DNS routing.

DNS routing request steps

1. The client makes a DNS request to get an object stored on Amazon S3.
2. The client receives one or more IP addresses for facilities that can process the request. In this example, the IP address is for Facility B.
3. The client makes a request to Amazon S3 Facility B.
4. Facility B returns a copy of the object to the client.

Temporary request redirection

A temporary redirect is a type of error response that signals to the requester that they should resend the request to a different endpoint. Due to the distributed nature of Amazon S3, requests can be temporarily routed to the wrong facility. This is most likely to occur immediately after buckets are created or deleted.

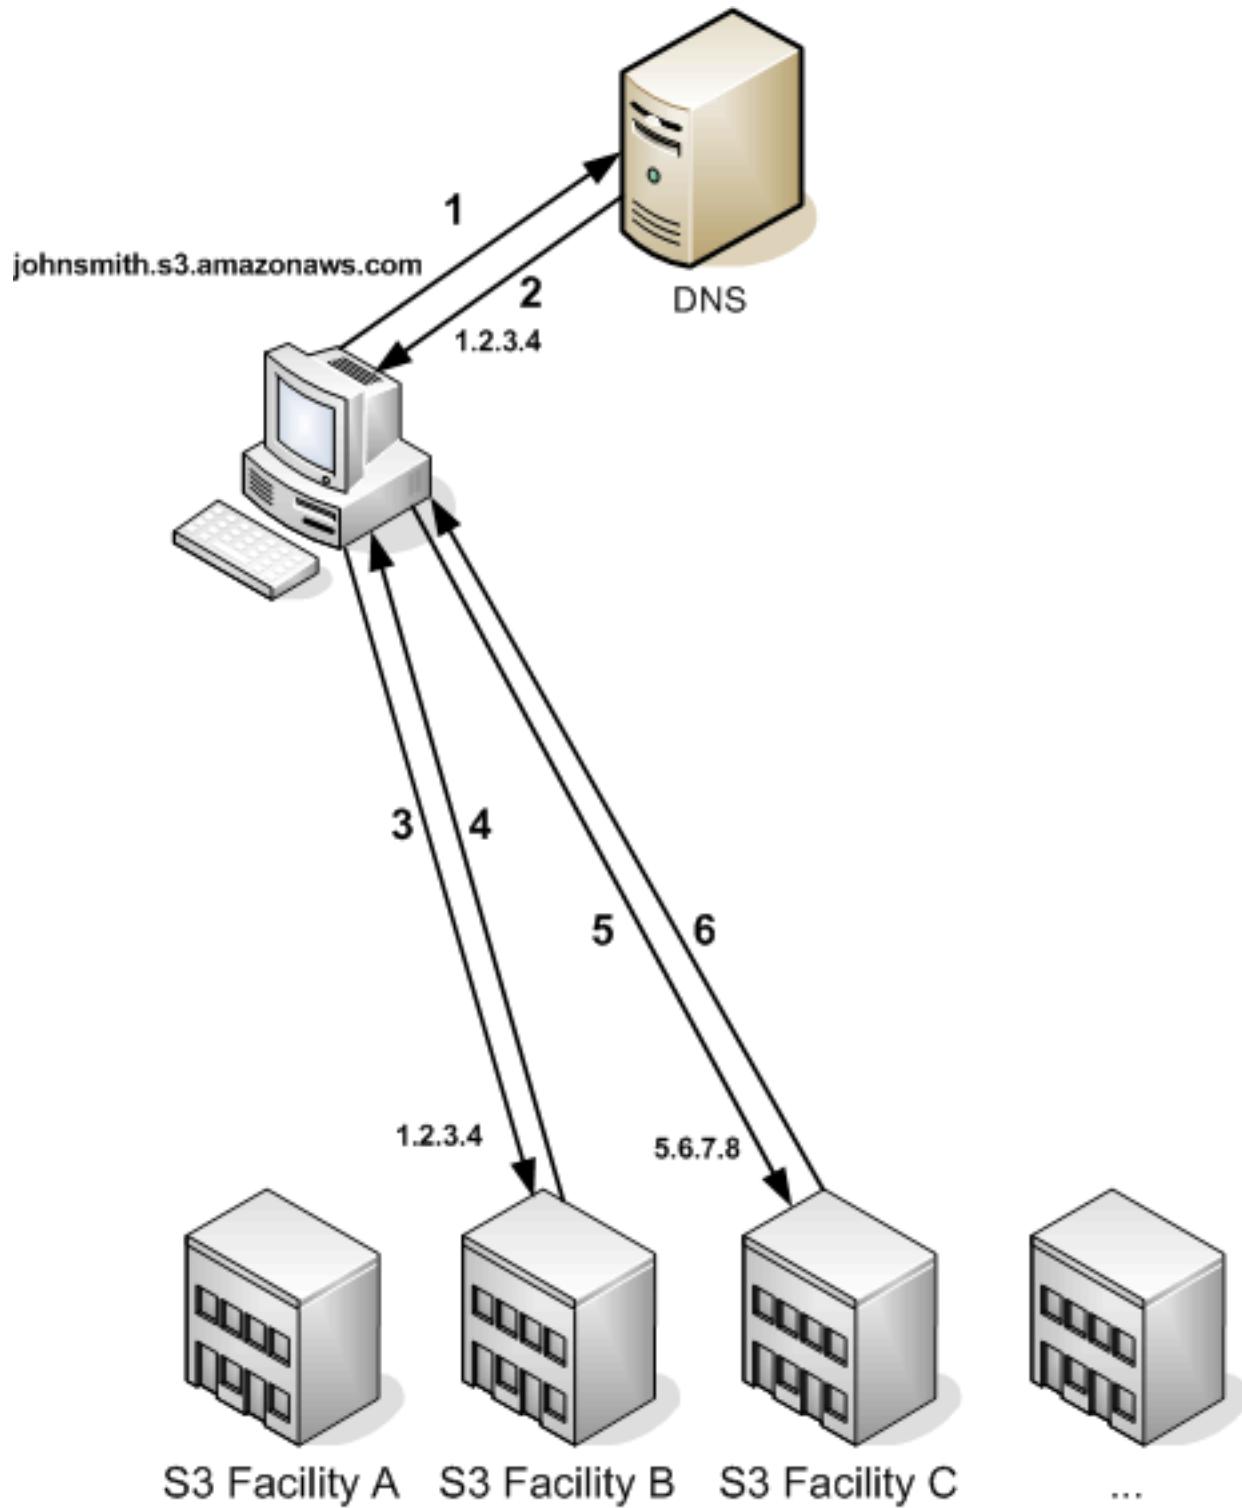

For example, if you create a new bucket and immediately make a request to the bucket, you might receive a temporary redirect, depending on the location constraint of the bucket. If you created the bucket in the US East (N. Virginia) AWS Region, you will not see the redirect because this is also the default Amazon S3 endpoint.

However, if the bucket is created in any other Region, any requests for the bucket go to the default endpoint while the bucket's DNS entry is propagated. The default endpoint redirects the request to the correct endpoint with an HTTP 302 response. Temporary redirects contain a URI to the correct facility, which you can use to immediately resend the request.

⚠ Important

Don't reuse an endpoint provided by a previous redirect response. It might appear to work (even for long periods of time), but it might provide unpredictable results and will eventually fail without notice.

The following figure and procedure shows an example of a temporary redirect.

Temporary request redirection steps

1. The client makes a DNS request to get an object stored on Amazon S3.
2. The client receives one or more IP addresses for facilities that can process the request.

3. The client makes a request to Amazon S3 Facility B.
4. Facility B returns a redirect indicating the object is available from Location C.
5. The client resends the request to Facility C.
6. Facility C returns a copy of the object.

Permanent request redirection

A permanent redirect indicates that your request addressed a resource inappropriately. For example, permanent redirects occur if you use a path-style request to access a bucket that was created using <CreateBucketConfiguration>. For more information, see [Accessing and listing an Amazon S3 bucket](#).

To help you find these errors during development, this type of redirect does not contain a Location HTTP header that allows you to automatically follow the request to the correct location. Consult the resulting XML error document for help using the correct Amazon S3 endpoint.

Request redirection examples

The following are examples of temporary request redirection responses.

REST API temporary redirect response

```
HTTP/1.1 307 Temporary Redirect
Location: http://awsexamplebucket1.s3-gztb4pa9sq.amazonaws.com/photos/puppy.jpg?
rk=e2c69a31
Content-Type: application/xml
Transfer-Encoding: chunked
Date: Fri, 12 Oct 2007 01:12:56 GMT
Server: AmazonS3

<?xml version="1.0" encoding="UTF-8"?>
<Error>
  <Code>TemporaryRedirect</Code>
  <Message>Please re-send this request to the specified temporary endpoint.
  Continue to use the original request endpoint for future requests.</Message>
  <Endpoint>awsexamplebucket1.s3-gztb4pa9sq.amazonaws.com</Endpoint>
</Error>
```

SOAP API temporary redirect response

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

```
<soapenv:Body>
<soapenv:Fault>
<Faultcode>soapenv:Client.TemporaryRedirect</Faultcode>
<Faultstring>Please re-send this request to the specified temporary endpoint.
Continue to use the original request endpoint for future requests.</Faultstring>
<Detail>
<Bucket>images</Bucket>
<Endpoint>s3-gztb4pa9sq.amazonaws.com</Endpoint>
</Detail>
</soapenv:Fault>
</soapenv:Body>
```

DNS considerations

One of the design requirements of Amazon S3 is extremely high availability. One of the ways we meet this requirement is by updating the IP addresses associated with the Amazon S3 endpoint in DNS as needed. These changes are automatically reflected in short-lived clients, but not in some long-lived clients. Long-lived clients will need to take special action to re-resolve the Amazon S3 endpoint periodically to benefit from these changes. For more information about virtual machines (VMs), refer to the following:

- For Java, Sun's JVM caches DNS lookups forever by default; go to the "InetAddress Caching" section of [the InetAddress documentation](#) for information on how to change this behavior.
- For PHP, the persistent PHP VM that runs in the most popular deployment configurations caches DNS lookups until the VM is restarted. Go to [the getHostByName PHP docs](#).

Handling REST and SOAP errors

Topics

- [The REST error response](#)
- [The SOAP error response](#)
- [Amazon S3 error best practices](#)

This section describes REST and SOAP errors and how to handle them.

 **Note**

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

The REST error response

If a REST request results in an error, the HTTP reply has:

- An XML error document as the response body
- Content-Type: application/xml
- An appropriate 3xx, 4xx, or 5xx HTTP status code

Following is an example of a REST Error Response.

```
<?xml version="1.0" encoding="UTF-8"?>
<Error>
  <Code>NoSuchKey</Code>
  <Message>The resource you requested does not exist</Message>
  <Resource>/mybucket/myfoto.jpg</Resource>
  <RequestId>4442587FB7D0A2F9</RequestId>
</Error>
```

For more information about Amazon S3 errors, go to [ErrorCodeList](#).

Response headers

Following are response headers returned by all operations:

- **x-amz-request-id**: A unique ID assigned to each request by the system. In the unlikely event that you have problems with Amazon S3, Amazon can use this to help troubleshoot the problem.
- **x-amz-id-2**: A special token that will help us to troubleshoot problems.

Error response

When an Amazon S3 request is in error, the client receives an error response. The exact format of the error response is API specific: For example, the REST error response differs from the SOAP error response. However, all error responses have common elements.

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

Error code

The error code is a string that uniquely identifies an error condition. It is meant to be read and understood by programs that detect and handle errors by type. Many error codes are common across SOAP and REST APIs, but some are API-specific. For example, `NoSuchKey` is universal, but `UnexpectedContent` can occur only in response to an invalid REST request. In all cases, SOAP fault codes carry a prefix as indicated in the table of error codes, so that a `NoSuchKey` error is actually returned in SOAP as `Client.NoSuchKey`.

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

Error message

The error message contains a generic description of the error condition in English. It is intended for a human audience. Simple programs display the message directly to the end user if they encounter an error condition they don't know how or don't care to handle. Sophisticated programs with

more exhaustive error handling and proper internationalization are more likely to ignore the error message.

Further details

Many error responses contain additional structured data meant to be read and understood by a developer diagnosing programming errors. For example, if you send a Content-MD5 header with a REST PUT request that doesn't match the digest calculated on the server, you receive a BadDigest error. The error response also includes as detail elements the digest we calculated, and the digest you told us to expect. During development, you can use this information to diagnose the error. In production, a well-behaved program might include this information in its error log.

The SOAP error response

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

In SOAP, an error result is returned to the client as a SOAP fault, with the HTTP response code 500. If you do not receive a SOAP fault, then your request was successful. The Amazon S3 SOAP fault code is comprised of a standard SOAP 1.1 fault code (either "Server" or "Client") concatenated with the Amazon S3-specific error code. For example: "Server.InternalError" or "Client.NoSuchBucket". The SOAP fault string element contains a generic, human readable error message in English. Finally, the SOAP fault detail element contains miscellaneous information relevant to the error.

For example, if you attempt to delete the object "Fred", which does not exist, the body of the SOAP response contains a "NoSuchKey" SOAP fault.

Example

```
<soapenv:Body>
<soapenv:Fault>
  <Faultcode>soapenv:Client.NoSuchKey</Faultcode>
  <Faultstring>The specified key does not exist.</Faultstring>
  <Detail>
    <Key>Fred</Key>
  </Detail>
```

```
</soapenv:Fault>  
</soapenv:Body>
```

For more information about Amazon S3 errors, go to [ErrorCodeList](#).

Amazon S3 error best practices

When designing an application for use with Amazon S3, it is important to handle Amazon S3 errors appropriately. This section describes issues to consider when designing your application.

Retry InternalErrors

Internal errors are errors that occur within the Amazon S3 environment.

Requests that receive an InternalError response might not have processed. For example, if a PUT request returns InternalError, a subsequent GET might retrieve the old value or the updated value.

If Amazon S3 returns an InternalError response, retry the request.

Tune application for repeated SlowDown errors

As with any distributed system, S3 has protection mechanisms which detect intentional or unintentional resource over-consumption and react accordingly. SlowDown errors can occur when a high request rate triggers one of these mechanisms. Reducing your request rate will decrease or eliminate errors of this type. Generally speaking, most users will not experience these errors regularly; however, if you would like more information or are experiencing high or unexpected SlowDown errors, please post to our [Amazon S3 developer forum](#) or sign up for AWS Support <https://aws.amazon.com/premiumsupport/>.

Isolate errors

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

Amazon S3 provides a set of error codes that are used by both the SOAP and REST API. The SOAP API returns standard Amazon S3 error codes. The REST API is designed to look like a standard HTTP server and interact with existing HTTP clients (e.g., browsers, HTTP client libraries, proxies, caches,

and so on). To ensure the HTTP clients handle errors properly, we map each Amazon S3 error to an HTTP status code.

HTTP status codes are less expressive than Amazon S3 error codes and contain less information about the error. For example, the `NoSuchKey` and `NoSuchBucket` Amazon S3 errors both map to the HTTP `404 Not Found` status code.

Although the HTTP status codes contain less information about the error, clients that understand HTTP, but not the Amazon S3 API, will usually handle the error correctly.

Therefore, when handling errors or reporting Amazon S3 errors to end users, use the Amazon S3 error code instead of the HTTP status code as it contains the most information about the error. Additionally, when debugging your application, you should also consult the human readable `<Details>` element of the XML error response.

Developer reference

This appendix include the following sections.

Topics

- [Appendix a: Using the SOAP API](#)
- [Appendix b: Authenticating requests \(AWS signature version 2\)](#)

Appendix a: Using the SOAP API

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

This section contains information specific to the Amazon S3 SOAP API.

Note

SOAP requests, both authenticated and anonymous, must be sent to Amazon S3 using SSL. Amazon S3 returns an error when you send a SOAP request over HTTP.

Topics

- [Common SOAP API elements](#)
- [Authenticating SOAP requests](#)
- [Setting access policy with SOAP](#)

Common SOAP API elements

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

You can interact with Amazon S3 using SOAP 1.1 over HTTP. The Amazon S3 WSDL, which describes the Amazon S3 API in a machine-readable way, is available at: <https://doc.s3.amazonaws.com/2006-03-01/AmazonS3.wsdl>. The Amazon S3 schema is available at <https://doc.s3.amazonaws.com/2006-03-01/AmazonS3.xsd>.

Most users will interact with Amazon S3 using a SOAP toolkit tailored for their language and development environment. Different toolkits will expose the Amazon S3 API in different ways. Please refer to your specific toolkit documentation to understand how to use it. This section illustrates the Amazon S3 SOAP operations in a toolkit-independent way by exhibiting the XML requests and responses as they appear "on the wire."

Common elements

You can include the following authorization-related elements with any SOAP request:

- **AWSAccessKeyId**: The AWS Access Key ID of the requester
- **Timestamp**: The current time on your system
- **Signature**: The signature for the request

Authenticating SOAP requests

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

Every non-anonymous request must contain authentication information to establish the identity of the principal making the request. In SOAP, the authentication information is put into the following elements of the SOAP request:

- Your AWS Access Key ID

Note

When making authenticated SOAP requests, temporary security credentials are not supported. For more information about types of credentials, see [Making requests](#).

- **Timestamp**: This must be a `dateTime` (go to <http://www.w3.org/TR/xmlschema-2/#dateTime>) in the Coordinated Universal Time (Greenwich Mean Time) time zone, such as `2009-01-01T12:00:00.000Z`. Authorization will fail if this timestamp is more than 15 minutes away from the clock on Amazon S3 servers.
- **Signature**: The RFC 2104 HMAC-SHA1 digest (go to <http://www.ietf.org/rfc/rfc2104.txt>) of the concatenation of "AmazonS3" + OPERATION + Timestamp, using your AWS Secret Access Key as the key. For example, in the following CreateBucket sample request, the signature element would contain the HMAC-SHA1 digest of the value "AmazonS3CreateBucket2009-01-01T12:00:00.000Z":

For example, in the following CreateBucket sample request, the signature element would contain the HMAC-SHA1 digest of the value "AmazonS3CreateBucket2009-01-01T12:00:00.000Z":

Example

```
<CreateBucket xmlns="https://doc.s3.amazonaws.com/2006-03-01">
  <Bucket>quotes</Bucket>
  <Acl>private</Acl>
```

```
<AWSAccessKeyId>AKIAIOSFODNN7EXAMPLE</AWSAccessKeyId>
<Timestamp>2009-01-01T12:00:00.000Z</Timestamp>
<Signature>Iuyz3d3P0aTou39dzbqaEXAMPLE=</Signature>
</CreateBucket>
```

Note

SOAP requests, both authenticated and anonymous, must be sent to Amazon S3 using SSL. Amazon S3 returns an error when you send a SOAP request over HTTP.

Important

Due to different interpretations regarding how extra time precision should be dropped, .NET users should take care not to send Amazon S3 overly specific time stamps. This can be accomplished by manually constructing DateTime objects with only millisecond precision.

Setting access policy with SOAP

Note

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

Access control can be set at the time a bucket or object is written by including the "AccessControlList" element with the request to CreateBucket, PutObjectInline, or PutObject. The AccessControlList element is described in [Identity and access management in Amazon S3](#). If no access control list is specified with these operations, the resource is created with a default access policy that gives the requester FULL_CONTROL access (this is the case even if the request is a PutObjectInline or PutObject request for an object that already exists).

Following is a request that writes data to an object, makes the object readable by anonymous principals, and gives the specified user FULL_CONTROL rights to the bucket (Most developers will want to give themselves FULL_CONTROL access to their own bucket).

Example

Following is a request that writes data to an object and makes the object readable by anonymous principals.

Sample Request

```
<PutObjectInline xmlns="https://doc.s3.amazonaws.com/2006-03-01">
  <Bucket>quotes</Bucket>
  <Key>Nelson</Key>
  <Metadata>
    <Name>Content-Type</Name>
    <Value>text/plain</Value>
  </Metadata>
  <Data>aGEtaGE=</Data>
  <ContentLength>5</ContentLength>
  <AccessControlList>
    <Grant>
      <Grantee xsi:type="CanonicalUser">
        <ID>75cc57f09aa0c8caeab4f8c24e99d10f8e7faebf76c078efc7c6caea54ba06a</ID>
        <DisplayName>chriscustomer</DisplayName>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
    <Grant>
      <Grantee xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/global/AllUsers<URI>
      </Grantee>
      <Permission>READ</Permission>
    </Grant>
  </AccessControlList>
  <AWSAccessKeyId>AKIAIOSFODNN7EXAMPLE</AWSAccessKeyId>
  <Timestamp>2009-03-01T12:00:00.183Z</Timestamp>
  <Signature>Iuyz3d3P0aTou39dzbqaEXAMPLE=</Signature>
</PutObjectInline>
```

Sample Response

```
<PutObjectInlineResponse xmlns="https://s3.amazonaws.com/doc/2006-03-01">
  <PutObjectInlineResponse>
    <ETag>"828ef3fdfa96f00ad9f27c383fc9ac7f"</ETag>
    <LastModified>2009-01-01T12:00:00.000Z</LastModified>
  </PutObjectInlineResponse>
```

```
</PutObjectInlineResponse>
```

The access control policy can be read or set for an existing bucket or object using the `GetBucketAccessControlPolicy`, `GetObjectAccessControlPolicy`, `SetBucketAccessControlPolicy`, and `SetObjectAccessControlPolicy` methods. For more information, see the detailed explanation of these methods.

Appendix b: Authenticating requests (AWS signature version 2)

Important

This section describes how to authenticate requests using AWS Signature Version 2. Signature Version 2 is being turned off (deprecated), Amazon S3 will only accept API requests that are signed using Signature Version 4. For more information, see [AWS Signature Version 2 Turned Off \(Deprecated\) for Amazon S3](#)

Signature Version 4 is supported in all AWS Regions, and it is the only version that is supported for new Regions. For more information, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

Amazon S3 offers you the ability to identify what API signature version was used to sign a request. It is important to identify if any of your workflows are utilizing Signature Version 2 signing and upgrading them to use Signature Version 4 to prevent impact to your business.

- If you are using CloudTrail event logs(recommended option), please see [Identifying Amazon S3 Signature Version 2 requests by using CloudTrail](#) on how to query and identify such requests.
- If you are using the Amazon S3 Server Access logs, see [Identifying Signature Version 2 requests by using Amazon S3 access logs](#)

Topics

- [Authenticating requests using the REST API](#)
- [Signing and authenticating REST requests](#)
- [Browser-based uploads using POST \(AWS signature version 2\)](#)

Authenticating requests using the REST API

When accessing Amazon S3 using REST, you must provide the following items in your request so the request can be authenticated:

Request elements

- **AWS access key Id** – Each request must contain the access key ID of the identity you are using to send your request.
- **Signature** – Each request must contain a valid request signature, or the request is rejected.

A request signature is calculated using your secret access key, which is a shared secret known only to you and AWS.

- **Time stamp** – Each request must contain the date and time the request was created, represented as a string in UTC.
- **Date** – Each request must contain the time stamp of the request.

Depending on the API action you're using, you can provide an expiration date and time for the request instead of or in addition to the time stamp. See the authentication topic for the particular action to determine what it requires.

Following are the general steps for authenticating requests to Amazon S3. It is assumed you have the necessary security credentials, access key ID and secret access key.

You

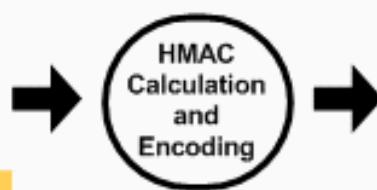

- 1 Create a request:

Request

AccessKeyId = ...
Action = ...
Timestamp = ...
ParameterA = ...

- 2 Create an HMAC-SHA1 signature:

String based on
request contents
+
Your Secret Access Key

- 3 Send the request and signature to AWS:

Request

AccessKeyId = ...
Action = ...
Timestamp = ...
ParameterA = ...

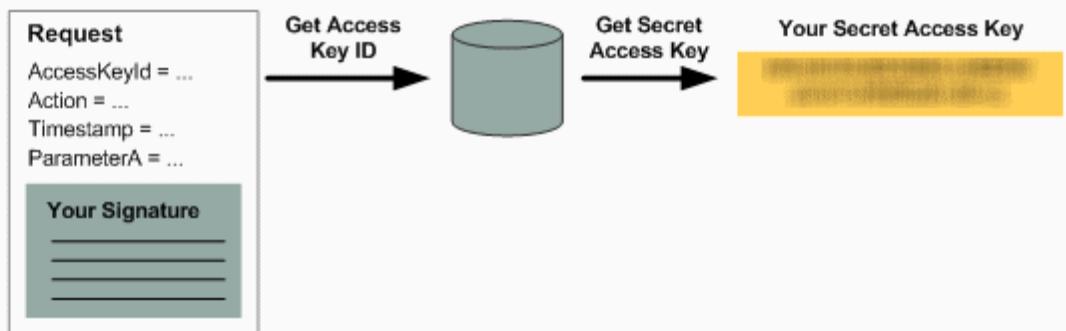

Your Signature

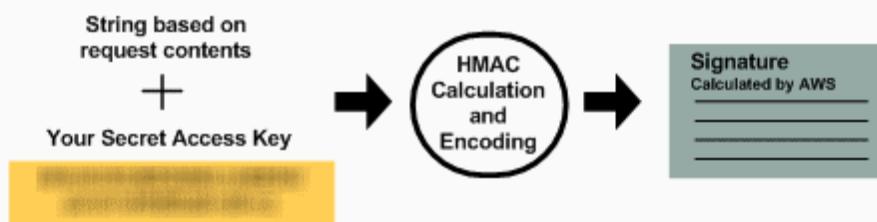

- | | |
|---|---|
| 1 | Construct a request to AWS. |
| 2 | Calculate the signature using your secret access key. |
| 3 | Send the request to Amazon S3. Include your access key ID and the signature in your request. Amazon S3 performs the next three steps. |

AWS

- 4** Retrieve your Secret Access Key:

- 5** Create an HMAC-SHA1 signature:

- 6** Compare the two signatures:

4 Amazon S3 uses the access key ID to look up your secret access key.

5 Amazon S3 calculates a signature from the request data and the secret access key using the same algorithm that you used to calculate the signature you sent in the request.

6 If the signature generated by Amazon S3 matches the one you sent in the request, the request is considered authentic. If the comparison fails, the request is discarded, and Amazon S3 returns an error response.

Detailed authentication information

For detailed information about REST authentication, see [Signing and authenticating REST requests](#).

Signing and authenticating REST requests

Topics

- [Using temporary security credentials](#)
- [The authentication header](#)
- [Request canonicalization for signing](#)
- [Constructing the CanonicalizedResource element](#)
- [Constructing the CanonicalizedAmzHeaders element](#)
- [Positional versus named HTTP header StringToSign elements](#)
- [Time stamp requirement](#)
- [Authentication examples](#)
- [REST request signing problems](#)
- [Query string request authentication alternative](#)

Note

This topic explains authenticating requests using Signature Version 2. Amazon S3 now supports the latest Signature Version 4. This latest signature version is supported in all regions and any new regions after January 30, 2014 will support only Signature Version 4. For more information, go to [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

Authentication is the process of proving your identity to the system. Identity is an important factor in Amazon S3 access control decisions. Requests are allowed or denied in part based on the identity of the requester. For example, the right to create buckets is reserved for registered developers and (by default) the right to create objects in a bucket is reserved for the owner of the bucket in question. As a developer, you'll be making requests that invoke these privileges, so you'll need to prove your identity to the system by authenticating your requests. This section shows you how.

Note

The content in this section does not apply to HTTP POST. For more information, see [Browser-based uploads using POST \(AWS signature version 2\)](#).

The Amazon S3 REST API uses a custom HTTP scheme based on a keyed-HMAC (Hash Message Authentication Code) for authentication. To authenticate a request, you first concatenate selected elements of the request to form a string. You then use your AWS secret access key to calculate the HMAC of that string. Informally, we call this process "signing the request," and we call the output of the HMAC algorithm the signature, because it simulates the security properties of a real signature. Finally, you add this signature as a parameter of the request by using the syntax described in this section.

When the system receives an authenticated request, it fetches the AWS secret access key that you claim to have and uses it in the same way to compute a signature for the message it received. It then compares the signature it calculated against the signature presented by the requester. If the two signatures match, the system concludes that the requester must have access to the AWS secret access key and therefore acts with the authority of the principal to whom the key was issued. If the two signatures do not match, the request is dropped and the system responds with an error message.

Example Authenticated Amazon S3 REST request

```
GET /photos/puppy.jpg HTTP/1.1
Host: awsexamplebucket1.us-west-1.s3.amazonaws.com
Date: Tue, 27 Mar 2007 19:36:42 +0000
```

```
Authorization: AWS AKIAIOSFODNN7EXAMPLE:
qgk2+6Sv9/oM7G3qLEjTH1a1l1g=
```

Using temporary security credentials

If you are signing your request using temporary security credentials (see [Making requests](#)), you must include the corresponding security token in your request by adding the x-amz-security-token header.

When you obtain temporary security credentials using the AWS Security Token Service API, the response includes temporary security credentials and a session token. You provide the session token value in the x-amz-security-token header when you send requests to Amazon S3. For information about the AWS Security Token Service API provided by IAM, go to [Action](#) in the [AWS Security Token Service API Reference Guide](#).

The authentication header

The Amazon S3 REST API uses the standard HTTP Authorization header to pass authentication information. (The name of the standard header is unfortunate because it carries authentication information, not authorization.) Under the Amazon S3 authentication scheme, the Authorization header has the following form:

```
Authorization: AWS AWSAccessKeyId:Signature
```

Developers are issued an AWS access key ID and AWS secret access key when they register. For request authentication, the *AWSAccessKeyId* element identifies the access key ID that was used to compute the signature and, indirectly, the developer making the request.

The *Signature* element is the RFC 2104 HMAC-SHA1 of selected elements from the request, and so the *Signature* part of the Authorization header will vary from request to request. If the request signature calculated by the system matches the *Signature* included with the request, the requester will have demonstrated possession of the AWS secret access key. The request will then be processed under the identity, and with the authority, of the developer to whom the key was issued.

Following is pseudogrammar that illustrates the construction of the Authorization request header. (In the example, \n means the Unicode code point U+000A, commonly called newline).

```
Authorization = "AWS" + " " + AWSAccessKeyId + ":" + Signature;

Signature = Base64( HMAC-SHA1( UTF-8-Encoding-Of(YourSecretAccessKey), UTF-8-Encoding-
Of( StringToSign ) ) );

StringToSign = HTTP-Verb + "\n" +
Content-MD5 + "\n" +
Content-Type + "\n" +
Date + "\n" +
CanonicalizedAmzHeaders +
CanonicalizedResource;

CanonicalizedResource = [ "/" + Bucket ] +
<HTTP-Request-URI, from the protocol name up to the query string> +
[ subresource, if present. For example "?acl", "?location", or "?logging"];

CanonicalizedAmzHeaders = <described below>
```

HMAC-SHA1 is an algorithm defined by [RFC 2104 - Keyed-Hashing for Message Authentication](#). The algorithm takes as input two byte-strings, a key and a message. For Amazon S3 request authentication, use your AWS secret access key (`YourSecretAccessKey`) as the key, and the UTF-8 encoding of the `StringToSign` as the message. The output of HMAC-SHA1 is also a byte string, called the digest. The `Signature` request parameter is constructed by Base64 encoding this digest.

Request canonicalization for signing

Recall that when the system receives an authenticated request, it compares the computed request signature with the signature provided in the request in `StringToSign`. For that reason, you must compute the signature by using the same method used by Amazon S3. We call the process of putting a request in an agreed-upon form for signing *canonicalization*.

Constructing the CanonicalizedResource element

`CanonicalizedResource` represents the Amazon S3 resource targeted by the request. Construct it for a REST request as follows:

Launch process

- 1 Start with an empty string ("").
- 2 If the request specifies a bucket using the HTTP Host header (virtual hosted-style), append the bucket name preceded by a "/" (e.g., "/bucketname"). For path-style requests and requests that don't address a bucket, do nothing. For more information about virtual hosted-style requests, see [Virtual hosting of buckets](#).

For a virtual hosted-style request "https://awsexamplebucket1.s3.us-west-1.amazonaws.com/photos/puppy.jpg", the `CanonicalizedResource` is "/awsexamplebucket1".

For the path-style request, "https://s3.us-west-1.amazonaws.com/awsexamplebucket1/photos/puppy.jpg", the `CanonicalizedResource` is "".
- 3 Append the path part of the un-decoded HTTP Request-URI, up-to but not including the query string.

For a virtual hosted-style request "https://awsexamplebucket1.s3.us-west-1.amazonaws.com/photos/puppy.jpg", the `CanonicalizedResource` is "/awsexamplebucket1/photos/puppy.jpg".

For a path-style request, "https://s3.us-west-1.amazonaws.com/awsexamplebucket1/photos/puppy.jpg", the CanonicalizedResource is "/awsexamplebucket1/photos/puppy.jpg". At this point, the CanonicalizedResource is the same for both the virtual hosted-style and path-style request.

For a request that does not address a bucket, such as [GET Service](#), append "/".

- 4 If the request addresses a subresource, such as ?versioning , ?location , ?acl, ?lifecycle , or ?versionid , append the subresource, its value if it has one, and the question mark. Note that in case of multiple subresources, subresources must be lexicographically sorted by subresource name and separated by '&', e.g., ?acl&versionId=*value*.

The subresources that must be included when constructing the CanonicalizedResource Element are acl, lifecycle, location, logging, notification, partNumber, policy, requestPayment, uploadId, uploads, versionId, versioning, versions, and website.

If the request specifies query string parameters overriding the response header values (see [Get Object](#)), append the query string parameters and their values. When signing, you do not encode these values; however, when making the request, you must encode these parameter values. The query string parameters in a GET request include response-content-type , response-content-language , response-expires , response-cache-control , response-content-disposition , and response-content-encoding .

The delete query string parameter must be included when you create the CanonicalizedResource for a multi-object Delete request.

Elements of the CanonicalizedResource that come from the HTTP Request-URI should be signed literally as they appear in the HTTP request, including URL-Encoding meta characters.

The CanonicalizedResource might be different than the HTTP Request-URI. In particular, if your request uses the HTTP Host header to specify a bucket, the bucket does not appear in the HTTP Request-URI. However, the CanonicalizedResource continues to include the bucket. Query string parameters might also appear in the Request-URI but are not included in CanonicalizedResource. For more information, see [Virtual hosting of buckets](#).

Constructing the CanonicalizedAmzHeaders element

To construct the CanonicalizedAmzHeaders part of StringToSign, select all HTTP request headers that start with 'x-amz-' (using a case-insensitive comparison), and use the following process.

CanonicalizedAmzHeaders process

- 1 Convert each HTTP header name to lowercase. For example, 'X-Amz-Date' becomes 'x-amz-date'.
- 2 Sort the collection of headers lexicographically by header name.
- 3 Combine header fields with the same name into one "header-name:comma-separate d-value-list" pair as prescribed by RFC 2616, section 4.2, without any spaces between values. For example, the two metadata headers 'x-amz-meta-username: fred' and 'x-amz-meta-username: barney' would be combined into the single header 'x-amz-meta-username: fred,barney'.
- 4 "Unfold" long headers that span multiple lines (as allowed by RFC 2616, section 4.2) by replacing the folding spaces (including new-line) by a single space.
- 5 Trim any spaces around the colon in the header. For example, the header 'x-amz-meta-username: fred,barney' would become 'x-amz-meta-username:fred,barney'.
- 6 Finally, append a newline character (U+000A) to each canonicalized header in the resulting list. Construct the CanonicalizedResource element by concatenating all headers in this list into a single string.

Positional versus named HTTP header StringToSign elements

The first few header elements of StringToSign (Content-Type, Date, and Content-MD5) are positional in nature. StringToSign does not include the names of these headers, only their values from the request. In contrast, the 'x-amz-' elements are named. Both the header names and the header values appear in StringToSign.

If a positional header called for in the definition of `StringToSign` is not present in your request (for example, `Content-Type` or `Content-MD5` are optional for `PUT` requests and meaningless for `GET` requests), substitute the empty string ("") for that position.

Time stamp requirement

A valid time stamp (using either the `HTTP Date` header or an `x-amz-date` alternative) is mandatory for authenticated requests. Furthermore, the client timestamp included with an authenticated request must be within 15 minutes of the Amazon S3 system time when the request is received. If not, the request will fail with the `RequestTimeTooSkewed` error code. The intention of these restrictions is to limit the possibility that intercepted requests could be replayed by an adversary. For stronger protection against eavesdropping, use the `HTTPS` transport for authenticated requests.

Note

The validation constraint on request date applies only to authenticated requests that do not use query string authentication. For more information, see [Query string request authentication alternative](#).

Some HTTP client libraries do not expose the ability to set the `Date` header for a request. If you have trouble including the value of the '`Date`' header in the canonicalized headers, you can set the timestamp for the request by using an '`x-amz-date`' header instead. The value of the `x-amz-date` header must be in one of the RFC 2616 formats (<http://www.ietf.org/rfc/rfc2616.txt>). When an `x-amz-date` header is present in a request, the system will ignore any `Date` header when computing the request signature. Therefore, if you include the `x-amz-date` header, use the empty string for the `Date` when constructing the `StringToSign`. See the next section for an example.

Authentication examples

The examples in this section use the (non-working) credentials in the following table.

Parameter	Value
<code>AWSAccessKeyId</code>	AKIAIOSFODNN7EXAMPLE
<code>AWSSecretAccessKey</code>	wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY

In the example `StringToSigns`, formatting is not significant, and `\n` means the Unicode code point U+000A, commonly called newline. Also, the examples use "+0000" to designate the time zone. You can use "GMT" to designate timezone instead, but the signatures shown in the examples will be different.

Object GET

This example gets an object from the `awsexamplebucket1` bucket.

Request	StringToSign
<pre>GET /photos/puppy.jpg HTTP/1.1 Host: awsexamplebucket1.us- west-1.s3.amazonaws.com Date: Tue, 27 Mar 2007 19:36:42 +0000</pre> <p><i>Authorization: AWS AKIAIOSFODNN7EXAMPLE</i> <i>qgk2+6Sv9/oM7G3qLEjTH1a1l1g=</i></p>	<pre>GET\n \n \n Tue, 27 Mar 2007 19:36:42 +0000\n /awsexamplebucket1/photos/puppy.jpg</pre>

Note that the CanonicalizedResource includes the bucket name, but the HTTP Request-URI does not. (The bucket is specified by the Host header.)

Note

The following Python script calculates the preceding signature, using the provided parameters. You can use this script to construct your own signatures, replacing the keys and `StringToSign` as appropriate.

```
import base64
import hmac
from hashlib import sha1

access_key = 'AKIAIOSFODNN7EXAMPLE'.encode("UTF-8")
secret_key = 'wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY'.encode("UTF-8")

string_to_sign = 'GET\n\n\nTue, 27 Mar 2007 19:36:42 +0000\n/awsexamplebucket1/
photos/puppy.jpg'.encode("UTF-8")
signature = base64.b64encode(
```

```
        hmac.new(  
            secret_key, string_to_sign, sha1  
        ).digest()  
    ).strip()  
  
print(f"AWS {access_key.decode()}: {signature.decode()}")
```

Object PUT

This example puts an object into the awsexamplebucket1 bucket.

Request	StringToSign
<pre>PUT /photos/puppy.jpg HTTP/1.1 Content-Type: image/jpeg Content-Length: 94328 Host: awsexamplebucket1.s3.us-wes t-1.amazonaws.com Date: Tue, 27 Mar 2007 21:15:45 +0000</pre> <p><i>Authorization: AWS AKIAIOSFODNN7EXAMP LE: iqRzw+ileNPu1fhspnRs8n0jjIA=</i></p>	<pre>PUT\n \nimage/jpeg\nTue, 27 Mar 2007 21:15:45 +0000\n/awsexamplebucket1/photos/puppy.jpg</pre>

Note the Content-Type header in the request and in the StringToSign. Also note that the Content-MD5 is left blank in the StringToSign, because it is not present in the request.

List

This example lists the content of the awsexamplebucket1 bucket.

Request	StringToSign
<pre>GET /?prefix=photos&max-keys=50&marker=puppy HTTP/1.1 User-Agent: Mozilla/5.0</pre>	<pre>GET\n \n</pre>

Request	StringToSign
<pre>Host: awsexamplebucket1.s3.us-west-1.amazonaws.com Date: Tue, 27 Mar 2007 19:42:41 +0000 <i>Authorization: AWS AKIAIOSFODNN7EXAMPLE:m0WP8eCtspQl5Ahe6L1SozdX9YA=</i></pre>	<pre>Tue, 27 Mar 2007 19:42:41 +0000\n /awsexamplebucket1/</pre>

Note the trailing slash on the CanonicalizedResource and the absence of query string parameters.

Fetch

This example fetches the access control policy subresource for the 'awsexamplebucket1' bucket.

Request	StringToSign
<pre>GET /?acl HTTP/1.1 Host: awsexamplebucket1.s3.us-west-1.amazonaws.com Date: Tue, 27 Mar 2007 19:44:46 +0000 <i>Authorization: AWS AKIAIOSFODNN7EXAMPLE:82ZHiFIjc+WbcwFKGUVEQspPn+0=</i></pre>	<pre>GET\n \n \n Tue, 27 Mar 2007 19:44:46 +0000\n /awsexamplebucket1/?acl</pre>

Notice how the subresource query string parameter is included in the CanonicalizedResource.

Delete

This example deletes an object from the 'awsexamplebucket1' bucket using the path-style and Date alternative.

Request	StringToSign
<pre>DELETE /awsexamplebucket1/photos/puppy.jpg HTTP/1.1 User-Agent: dotnet Host: s3.us-west-1.amazonaws.com Date: Tue, 27 Mar 2007 21:20:27 +0000</pre>	<pre>DELETE\n \n \n Tue, 27 Mar 2007 21:20:26 +0000\n</pre>

Request	StringToSign
<pre>x-amz-date: Tue, 27 Mar 2007 21:20:26 +0000 Authorization: AWS AKIAIOSFODNN7EXAMP LE:XbyTlbQdu9Xw5o8P4iMwPktxQd8=</pre>	<pre>/awsexamplebucket1/photos/puppy.jpg</pre>

Note how we used the alternate 'x-amz-date' method of specifying the date (because our client library prevented us from setting the date, say). In this case, the x-amz-date takes precedence over the Date header. Therefore, date entry in the signature must contain the value of the x-amz-date header.

Upload

This example uploads an object to a CNAME style virtual hosted bucket with metadata.

Request	StringToSign
<pre>PUT /db-backup.dat.gz HTTP/1.1 User-Agent: curl/7.15.5 Host: static.example.com:8080 Date: Tue, 27 Mar 2007 21:06:08 +0000 x-amz-acl: public-read content-type: application/x-download Content-MD5: 4gJE4saaMU4BqNR0kLY+lw== X-Amz-Meta-ReviewedBy: joe@example.com X-Amz-Meta-ReviewedBy: jane@example.com X-Amz-Meta-FileChecksum: 0x02661779 X-Amz-Meta-ChecksumAlgorithm: crc32 Content-Disposition: attachment; filename=database.dat Content-Encoding: gzip Content-Length: 5913339 Authorization: AWS AKIAIOSFODNN7EXAMP LE: jtBQa0Aq+DkULFI8qrpwIjGEx0E=</pre>	<pre>PUT\n 4gJE4saaMU4BqNR0kLY+lw==\n application/x-download\n Tue, 27 Mar 2007 21:06:08 +0000\n x-amz-acl:public-read\n x-amz-meta-checksumalgorithm:crc32\n x-amz-meta-filechecksum:0x026 61779\n x-amz-meta-reviewedby: joe@example.com,jane@example.com \n /static.example.com/db-backup.dat .gz</pre>

Notice how the 'x-amz-' headers are sorted, trimmed of extra spaces, and converted to lowercase. Note also that multiple headers with the same name have been joined using commas to separate values.

Note how only the Content-Type and Content-MD5 HTTP entity headers appear in the StringToSign. The other Content-* entity headers do not.

Again, note that the CanonicalizedResource includes the bucket name, but the HTTP Request-URI does not. (The bucket is specified by the Host header.)

List all my buckets

Request	StringToSign
<pre>GET / HTTP/1.1 Host: s3.us-west-1.amazonaws.com Date: Wed, 28 Mar 2007 01:29:59 +0000 <i>Authorization: AWS AKIAIOSFODNN7EXAMPLE:qGdzdE RIC03wnaRNKh60qZehG9s=</i></pre>	<pre>GET\n \n \n Wed, 28 Mar 2007 01:29:59 +0000\n /</pre>

Unicode keys

Request	StringToSign
<pre>GET /dictionary/fran%C3%A7ais/pr %c3%a9 HTTP/1.1 Host: s3.us-west-1.amazonaws.com Date: Wed, 28 Mar 2007 01:49:49 +0000 <i>Authorization: AWS AKIAIOSFODNN7EXAMPLE:DNEZGsoieTZ92F3bUFSPQcbGmlM=</i></pre>	<pre>GET\n \n \n Wed, 28 Mar 2007 01:49:49 +0000\n /dictionary/fran%C3%A7ais/pr %c3%a9</pre>

Note

The elements in StringToSign that were derived from the Request-URI are taken literally, including URL-Encoding and capitalization.

REST request signing problems

When REST request authentication fails, the system responds to the request with an XML error document. The information contained in this error document is meant to help developers diagnose the problem. In particular, the `StringToSign` element of the `SignatureDoesNotMatch` error document tells you exactly what request canonicalization the system is using.

Some toolkits silently insert headers that you do not know about beforehand, such as adding the header `Content-Type` during a `PUT`. In most of these cases, the value of the inserted header remains constant, allowing you to discover the missing headers by using tools such as Ethereal or `tcpmon`.

Query string request authentication alternative

You can authenticate certain types of requests by passing the required information as query-string parameters instead of using the `Authorization` HTTP header. This is useful for enabling direct third-party browser access to your private Amazon S3 data without proxying the request. The idea is to construct a "presigned" request and encode it as a URL that an end-user's browser can retrieve. Additionally, you can limit a presigned request by specifying an expiration time.

For more information on using query parameters to authenticate requests , see [Authenticating Requests: Using Query Parameters \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*. For examples of using the AWS SDKs to generating presigned URLs, see [Sharing objects with presigned URLs](#).

Creating a signature

Following is an example query string authenticated Amazon S3 REST request.

```
GET /photos/puppy.jpg
?AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Expires=1141889120&Signature=vjbyPxybdZaNmGa
%2ByT272YEAiv4%3D HTTP/1.1
Host: awsexamplebucket1.s3.us-west-1.amazonaws.com
Date: Mon, 26 Mar 2007 19:37:58 +0000
```

The query string request authentication method doesn't require any special HTTP headers. Instead, the required authentication elements are specified as query string parameters:

Query string parameter name	Example value	Description
AWSAccessKeyId	AKIAIOSFODNN7EXAMPLE	Your AWS access key ID. Specifies the AWS secret access key used to sign the request and, indirectly, the identity of the developer making the request.
Expires	1141889120	The time when the signature expires, specified as the number of seconds since the epoch (00:00:00 UTC on January 1, 1970). A request received after this time (according to the server) will be rejected.
Signature	vjbyPxybdZaNmGa%2ByT272YEAiv4%3D	The URL encoding of the Base64 encoding of the HMAC-SHA1 of StringToSign.

The query string request authentication method differs slightly from the ordinary method but only in the format of the `Signature` request parameter and the `StringToSign` element. Following is pseudo-grammar that illustrates the query string request authentication method.

```

Signature = URL-Encode( Base64( HMAC-SHA1( YourSecretAccessKey, UTF-8-Encoding-Of( StringToSign ) ) ) );

StringToSign = HTTP-VERB + "\n" +
  Content-MD5 + "\n" +
  Content-Type + "\n" +
  Expires + "\n" +
  CanonicalizedAmzHeaders +
  CanonicalizedResource;

```

`YourSecretAccessKey` is the AWS secret access key ID that Amazon assigns to you when you sign up to be an Amazon Web Service developer. Notice how the `Signature` is URL-Encoded to

make it suitable for placement in the query string. Note also that in `StringToSign`, the HTTP Date positional element has been replaced with Expires. The CanonicalizedAmzHeaders and CanonicalizedResource are the same.

Note

In the query string authentication method, you do not use the Date or the x-amz-date request header when calculating the string to sign.

Query string request authentication

Request	StringToSign
<pre>GET /photos/puppy.jpg?AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Signature=NpgCjnDzrM%2BWFzoENXmpNDUsSn8%3D&Expires=1175139620 HTTP/1.1 Host: awsexamplebucket1.s3.us-west-1.amazonaws.com</pre>	<pre>GET\n\n\n1175139620\n/awsexamplebucket1/photos/puppy.jpg</pre>

We assume that when a browser makes the GET request, it won't provide a Content-MD5 or a Content-Type header, nor will it set any x-amz- headers, so those parts of the StringToSign are left blank.

Using Base64 encoding

HMAC request signatures must be Base64 encoded. Base64 encoding converts the signature into a simple ASCII string that can be attached to the request. Characters that could appear in the signature string like plus (+), forward slash (/), and equals (=) must be encoded if used in a URI. For example, if the authentication code includes a plus (+) sign, encode it as %2B in the request. Encode a forward slash as %2F and equals as %3D.

For examples of Base64 encoding, refer to the Amazon S3 [Authentication examples](#).

Browser-based uploads using POST (AWS signature version 2)

Amazon S3 supports POST, which allows your users to upload content directly to Amazon S3. POST is designed to simplify uploads, reduce upload latency, and save you money on applications where users upload data to store in Amazon S3.

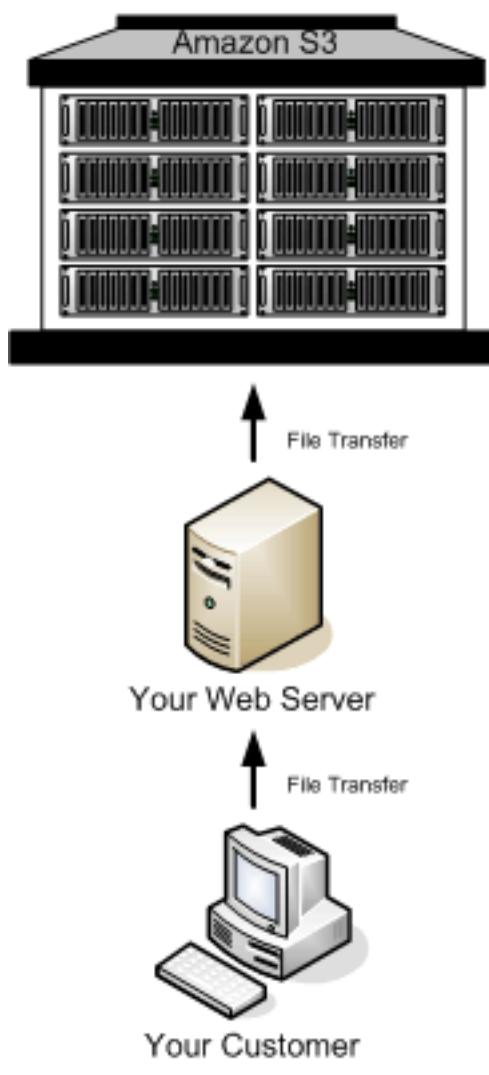

Note

The request authentication discussed in this section is based on AWS Signature Version 2, a protocol for authenticating inbound API requests to AWS services.

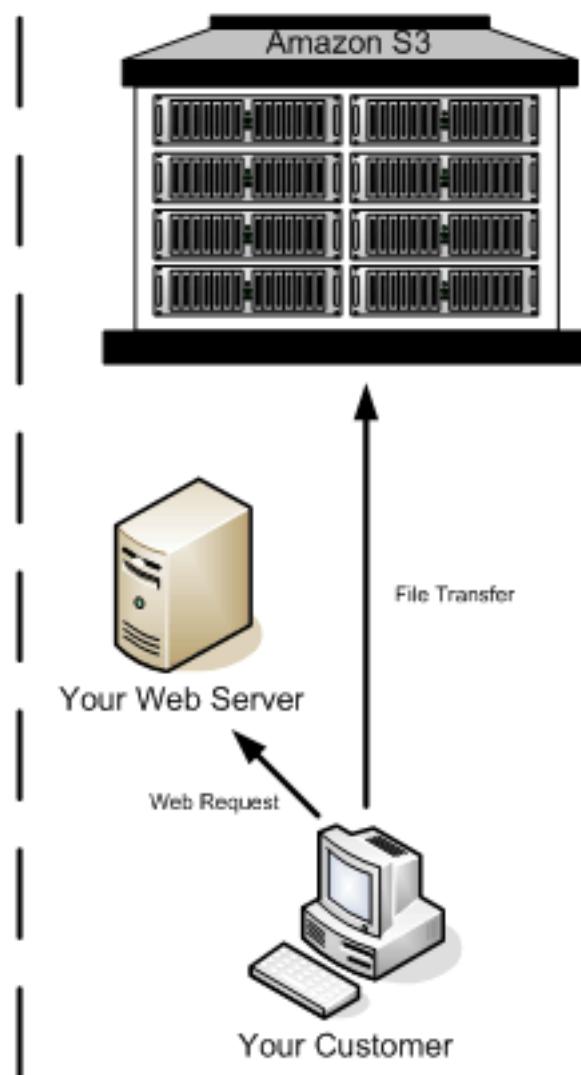

Amazon S3 now supports Signature Version 4, a protocol for authenticating inbound API requests to AWS services, in all AWS Regions. At this time, AWS Regions created before January 30, 2014 will continue to support the previous protocol, Signature Version 2. Any new regions after January 30, 2014 will support only Signature Version 4 and therefore all requests to those regions must be made with Signature Version 4. For more information, see [Authenticating Requests in Browser-Based Uploads Using POST \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

The following figure shows an upload using Amazon S3 POST.

Proxying Amazon S3 PUTs

Using Amazon S3 POST

Uploading using POST

- 1 The user opens a web browser and accesses your web page.
- 2 Your web page contains an HTTP form that contains all the information necessary for the user to upload content to Amazon S3.
- 3 The user uploads content directly to Amazon S3.

Note

Query string authentication is not supported for POST.

HTML forms (AWS signature version 2)

Topics

- [HTML form encoding](#)
- [HTML form declaration](#)
- [HTML form fields](#)
- [Policy construction](#)
- [Constructing a signature](#)
- [Redirection](#)

When you communicate with Amazon S3, you normally use the REST or SOAP API to perform put, get, delete, and other operations. With POST, users upload data directly to Amazon S3 through their browsers, which cannot process the SOAP API or create a REST PUT request.

 **Note**

SOAP support over HTTP is deprecated, but SOAP is still available over HTTPS. New Amazon S3 features are not supported for SOAP. Instead of using SOAP, we recommend that you use either the REST API or the AWS SDKs.

To allow users to upload content to Amazon S3 by using their browsers, you use HTML forms. HTML forms consist of a form declaration and form fields. The form declaration contains high-level information about the request. The form fields contain detailed information about the request, as well as the policy that is used to authenticate it and ensure that it meets the conditions that you specify.

 **Note**

The form data and boundaries (excluding the contents of the file) cannot exceed 20 KB.

This section explains how to use HTML forms.

HTML form encoding

The form and policy must be UTF-8 encoded. You can apply UTF-8 encoding to the form by specifying it in the HTML heading or as a request header.

 **Note**

The HTML form declaration does not accept query string authentication parameters.

The following is an example of UTF-8 encoding in the HTML heading:

```
<html>
  <head>
    ...
    <meta http-equiv="Content-Type" content="text/html; charset=UTF-8" />
    ...
  </head>
  <body>
```

The following is an example of UTF-8 encoding in a request header:

```
Content-Type: text/html; charset=UTF-8
```

HTML form declaration

The form declaration has three components: the action, the method, and the enclosure type. If any of these values is improperly set, the request fails.

The action specifies the URL that processes the request, which must be set to the URL of the bucket. For example, if the name of your bucket is awsexamplebucket1 and the Region is US West (N. California), the URL is <https://awsexamplebucket1.s3.us-west-1.amazonaws.com/>.

 **Note**

The key name is specified in a form field.

The method must be POST.

The enclosure type (enctype) must be specified and must be set to multipart/form-data for both file uploads and text area uploads. For more information, go to [RFC 1867](#).

Example

The following example is a form declaration for the bucket "awsexamplebucket1".

```
<form action="https://awsexamplebucket1.s3.us-west-1.amazonaws.com/" method="post"
      enctype="multipart/form-data">
```

HTML form fields

The following table describes fields that can be used within an HTML form.

Note

The variable \${filename} is automatically replaced with the name of the file provided by the user and is recognized by all form fields. If the browser or client provides a full or partial path to the file, only the text following the last slash (/) or backslash (\) will be used. For example, "C:\Program Files\directory1\file.txt" will be interpreted as "file.txt". If no file or file name is provided, the variable is replaced with an empty string.

Field name	Description	Required
AWSAccessKeyId	The AWS Access Key ID of the owner of the bucket who grants an anonymous user access for a request that satisfies the set of constraints in the policy. This field is required if the request includes a policy document.	Conditional
acl	An Amazon S3 access control list (ACL). If an invalid access control list is specified, an error is generated. For more information on ACLs, see Access control lists (ACLs) .	No

Field name	Description	Required
	<p>Type: String</p> <p>Default: private</p> <p>Valid Values: private public-read public-read-write aws-exec-read authenticated-read bucket-owner-read bucket-owner-full-control</p>	
Cache-Control, Content-Type, Content-Disposition, Content-Encoding, Expires	REST-specific headers. For more information, see PUT Object .	No
key	<p>The name of the uploaded key.</p> <p>To use the filename provided by the user, use the \${filename} variable. For example, if user Betty uploads the file lolcatz.jpg and you specify /user/betty/\${filename}, the file is stored as /user/betty/lolcatz.jpg.</p> <p>For more information, see Working with object metadata.</p>	Yes
policy	Security policy describing what is permitted in the request. Requests without a security policy are considered anonymous and will succeed only on publicly writable buckets.	No

Field name	Description	Required
success_action_redirect, redirect	<p>The URL to which the client is redirected upon successful upload. Amazon S3 appends the bucket, key, and etag values as query string parameters to the URL.</p> <p>If success_action_redirect is not specified, Amazon S3 returns the empty document type specified in the success_action_status field.</p> <p>If Amazon S3 cannot interpret the URL, it ignores the field.</p> <p>If the upload fails, Amazon S3 displays an error and does not redirect the user to a URL.</p> <p>For more information, see Redirection.</p> <div data-bbox="612 1045 1281 1309" style="border: 1px solid #ccc; padding: 10px;"><p> Note The redirect field name is deprecated and support for the redirect field name will be removed in the future.</p></div>	No

Field name	Description	Required
success_action_status	<p>The status code returned to the client upon successful upload if success_action_redirect is not specified.</p> <p>Valid values are 200, 201, or 204 (default).</p> <p>If the value is set to 200 or 204, Amazon S3 returns an empty document with a 200 or 204 status code.</p> <p>If the value is set to 201, Amazon S3 returns an XML document with a 201 status code. For information about the content of the XML document, see POST Object.</p> <p>If the value is not set or if it is set to an invalid value, Amazon S3 returns an empty document with a 204 status code.</p>	No

 **Note**

Some versions of the Adobe Flash player do not properly handle HTTP responses with an empty body. To support uploads through Adobe Flash, we recommend setting success_action_status to 201.

Field name	Description	Required
signature	<p>The HMAC signature constructed by using the secret access key that corresponds to the provided AWSAccessKeyId. This field is required if a policy document is included with the request.</p> <p>For more information, see Identity and access management in Amazon S3.</p>	Conditional
x-amz-security-token	<p>A security token used by session credentials</p> <p>If the request is using Amazon DevPay then it requires two x-amz-security-token form fields: one for the product token and one for the user token.</p> <p>If the request is using session credentials, then it requires one x-amz-security-token form. For more information, see Temporary Security Credentials in the <i>IAM User Guide</i>.</p>	No
Other field names prefixed with x-amz-meta-	<p>User-specified metadata.</p> <p>Amazon S3 does not validate or use this data.</p> <p>For more information, see PUT Object.</p>	No

Field name	Description	Required
file	<p>File or text content.</p> <p>The file or content must be the last field in the form. Any fields below it are ignored.</p> <p>You cannot upload more than one file at a time.</p>	Yes

Policy construction

- [Condition matching](#)
- [Character escaping](#)

The policy is a UTF-8 and Base64-encoded JSON document that specifies conditions that the request must meet and is used to authenticate the content. Depending on how you design your policy documents, you can use them per upload, per user, for all uploads, or according to other designs that meet your needs.

 **Note**

Although the policy document is optional, we highly recommend it over making a bucket publicly writable.

The following is an example of a policy document:

```
{ "expiration": "2007-12-01T12:00:00.000Z",  
  "conditions": [  
    {"acl": "public-read"} ]}
```

```
{"bucket": "awsexamplebucket1" },  
["starts-with", "$key", "user/eric/"],  
]  
}
```

The policy document contains the expiration and conditions.

Expiration

The expiration element specifies the expiration date of the policy in ISO 8601 UTC date format. For example, "2007-12-01T12:00:00.000Z" specifies that the policy is not valid after midnight UTC on 2007-12-01. Expiration is required in a policy.

Conditions

The conditions in the policy document validate the contents of the uploaded object. Each form field that you specify in the form (except AWSAccessKeyId, signature, file, policy, and field names that have an x-ignore- prefix) must be included in the list of conditions.

Note

If you have multiple fields with the same name, the values must be separated by commas. For example, if you have two fields named "x-amz-meta-tag" and the first one has a value of "Ninja" and second has a value of "Stallman", you would set the policy document to Ninja, Stallman.

All variables within the form are expanded before the policy is validated. Therefore, all condition matching should be performed against the expanded fields. For example, if you set the key field to user/betty/\${filename}, your policy might be ["starts-with", "\$key", "user/betty/"]. Do not enter ["starts-with", "\$key", "user/betty/\${filename}"]. For more information, see [Condition matching](#).

The following table describes policy document conditions.

Element name	Description
acl	<p>Specifies conditions that the ACL must meet.</p> <p>Supports exact matching and starts-with .</p>
content-length-range	<p>Specifies the minimum and maximum allowable size for the uploaded content.</p> <p>Supports range matching.</p>
Cache-Control, Content-Type, Content-Disposition, Content-Encoding, Expires	<p>REST-specific headers.</p> <p>Supports exact matching and starts-with .</p>
key	<p>The name of the uploaded key.</p> <p>Supports exact matching and starts-with .</p>
success_action_redirect, redirect	<p>The URL to which the client is redirected upon successful upload.</p> <p>Supports exact matching and starts-with .</p>
success_action_status	<p>The status code returned to the client upon successful upload if success_action_redirect is not specified.</p> <p>Supports exact matching.</p>
x-amz-security-token	<p>Amazon DevPay security token.</p> <p>Each request that uses Amazon DevPay requires two x-amz-security-token form fields: one for the product token and one for the user token. As a result, the values must be separated by commas. For example, if the user token is eW91dHVIZQ== and the product</p>

Element name	Description
	token is b0hnNVNKwVJIQTA= , you set the policy entry to: { "x-amz-security-token": "eW91dHVIZQ==,b0hnNVNKwVJIQTA=" } .
Other field names prefixed with x-amz-meta-	User-specified metadata. Supports exact matching and starts-with .

Note

If your toolkit adds additional fields (e.g., Flash adds filename), you must add them to the policy document. If you can control this functionality, prefix x-ignore- to the field so Amazon S3 ignores the feature and it won't affect future versions of this feature.

Condition matching

The following table describes condition matching types. Although you must specify one condition for each form field that you specify in the form, you can create more complex matching criteria by specifying multiple conditions for a form field.

Condition	Description
Exact Matches	<p>Exact matches verify that fields match specific values. This example indicates that the ACL must be set to public-read:</p> <pre data-bbox="388 1501 763 1537">{ "acl": "public-read" }</pre> <p>This example is an alternate way to indicate that the ACL must be set to public-read:</p> <pre data-bbox="388 1769 894 1805">["eq", "\$acl", "public-read"]</pre>

Condition	Description
Starts With	<p>If the value must start with a certain value, use <code>starts-with</code>. This example indicates that the key must start with user/betty:</p> <pre data-bbox="393 354 1002 388">["starts-with", "\$key", "user/betty/"]</pre>
Matching Any Content	<p>To configure the policy to allow any content within a <code>field</code>, use <code>starts-with</code> with an empty value. This example allows any <code>success_action_redirect</code>:</p> <pre data-bbox="393 677 1144 711">["starts-with", "\$success_action_redirect", ""]</pre>
Specifying Ranges	<p>For fields that accept ranges, separate the upper and lower ranges with a comma. This example allows a file size from 1 to 10 megabytes:</p> <pre data-bbox="393 973 1083 1007">["content-length-range", 1048579, 10485760]</pre>

Character escaping

The following table describes characters that must be escaped within a policy document.

Escape sequence	Description
\\\	Backslash
\\$	Dollar sign
\b	Backspace
\f	Form feed

Escape sequence	Description
\n	New line
\r	Carriage return
\t	Horizontal tab
\v	Vertical tab
\uXXXX	All Unicode characters

Constructing a signature

Step	Description
1	Encode the policy by using UTF-8.
2	Encode those UTF-8 bytes by using Base64.
3	Sign the policy with your secret access key by using HMAC SHA-1.
4	Encode the SHA-1 signature by using Base64.

For general information about authentication, see [Identity and access management in Amazon S3](#).

Redirection

This section describes how to handle redirects.

General redirection

On completion of the POST request, the user is redirected to the location that you specified in the `success_action_redirect` field. If Amazon S3 cannot interpret the URL, it ignores the `success_action_redirect` field.

If `success_action_redirect` is not specified, Amazon S3 returns the empty document type specified in the `success_action_status` field.

If the POST request fails, Amazon S3 displays an error and does not provide a redirect.

Pre-upload redirection

If your bucket was created using `<CreateBucketConfiguration>`, your end users might require a redirect. If this occurs, some browsers might handle the redirect incorrectly. This is relatively rare but is most likely to occur right after a bucket is created.

Upload examples (AWS signature version 2)

Topics

- [File upload](#)
- [Text area upload](#)

Note

The request authentication discussed in this section is based on AWS Signature Version 2, a protocol for authenticating inbound API requests to AWS services.

Amazon S3 now supports Signature Version 4, a protocol for authenticating inbound API requests to AWS services, in all AWS Regions. At this time, AWS Regions created before January 30, 2014 will continue to support the previous protocol, Signature Version 2. Any new regions after January 30, 2014 will support only Signature Version 4 and therefore all requests to those regions must be made with Signature Version 4. For more information, see [Examples: Browser-Based Upload using HTTP POST \(Using AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

File upload

This example shows the complete process for constructing a policy and form that can be used to upload a file attachment.

Policy and form construction

The following policy supports uploads to Amazon S3 for the awsexamplebucket1 bucket.

```
{ "expiration": "2007-12-01T12:00:00.000Z",
  "conditions": [
    {"bucket": "awsexamplebucket1"},
    ["starts-with", "$key", "user/eric/"],
    {"acl": "public-read"},
    {"success_action_redirect": "https://awsexamplebucket1.s3.us-west-1.amazonaws.com/
successful_upload.html"},
    ["starts-with", "$Content-Type", "image/"],
    {"x-amz-meta-uuid": "14365123651274"},
    ["starts-with", "$x-amz-meta-tag", ""]
  ]
}
```

This policy requires the following:

- The upload must occur before 12:00 UTC on December 1, 2007.
- The content must be uploaded to the awsexamplebucket1 bucket.
- The key must start with "user/eric/".
- The ACL is set to public-read.
- The success_action_redirect is set to https://awsexamplebucket1.s3.us-west-1.amazonaws.com/ successful_upload.html.
- The object is an image file.
- The x-amz-meta-uuid tag must be set to 14365123651274.
- The x-amz-meta-tag can contain any value.

The following is a Base64-encoded version of this policy.

```
eyAizXhwaXJhdGlvbii6ICiYMDA3LTEyLTAxVDEyOjAwOjAwLjAwMFoiLAogICJjb25kaXRpb25zIjogWwogICAgeyJidWN
```

Using your credentials create a signature, for example `0RavWzkygo6QX9caELEqKi9kDbU=` is the signature for the preceding policy document.

The following form supports a POST request to the DOC-EXAMPLE-BUCKET bucket that uses this policy.

```
<html>
<head>
  ...
  <meta http-equiv="Content-Type" content="text/html; charset=UTF-8" />
  ...
</head>
<body>
  ...
<form action="https://DOC-EXAMPLE-BUCKET.s3.us-west-1.amazonaws.com/" method="post"
enctype="multipart/form-data">
  Key to upload: <input type="input" name="key" value="user/eric/" /><br />
  <input type="hidden" name="acl" value="public-read" />
  <input type="hidden" name="success_action_redirect" value="https://
awsexamplebucket1.s3.us-west-1.amazonaws.com/successful_upload.html" />
  Content-Type: <input type="input" name="Content-Type" value="image/jpeg" /><br />
  <input type="hidden" name="x-amz-meta-uuid" value="14365123651274" />
  Tags for File: <input type="input" name="x-amz-meta-tag" value="" /><br />
  <input type="hidden" name="AWSAccessKeyId" value="AKIAIOSFODNN7EXAMPLE" />
  <input type="hidden" name="Policy" value="POLICY" />
  <input type="hidden" name="Signature" value="SIGNATURE" />
  File: <input type="file" name="file" /> <br />
  <!-- The elements after this will be ignored -->
  <input type="submit" name="submit" value="Upload to Amazon S3" />
</form>
  ...
</html>
```

Sample request

This request assumes that the image uploaded is 117,108 bytes; the image data is not included.

```

Text area upload

Topics

- [Policy and form construction](#)
- [Sample request](#)
- [Sample response](#)

The following example shows the complete process for constructing a policy and form to upload a text area. Uploading a text area is useful for submitting user-created content, such as blog postings.

Policy and form construction

The following policy supports text area uploads to Amazon S3 for the awsexamplebucket1 bucket.

```
{ "expiration": "2007-12-01T12:00:00.000Z",
  "conditions": [
```

```
{"bucket": "awsexamplebucket1"},  
["starts-with", "$key", "user/eric/"],  
{"acl": "public-read"},  
{"success_action_redirect": "https://awsexamplebucket1.s3.us-west-1.amazonaws.com/  
new_post.html"},  
[{"eq", "$Content-Type", "text/html"},  
 {"x-amz-meta-uuid": "14365123651274"},  
 ["starts-with", "$x-amz-meta-tag", ""]]  
]  
}
```

This policy requires the following:

- The upload must occur before 12:00 GMT on 2007-12-01.
- The content must be uploaded to the awsexamplebucket1 bucket.
- The key must start with "user/eric/".
- The ACL is set to public-read.
- The success_action_redirect is set to https://awsexamplebucket1.s3.us-west-1.amazonaws.com/
new_post.html.
- The object is HTML text.
- The x-amz-meta-uuid tag must be set to 14365123651274.
- The x-amz-meta-tag can contain any value.

Following is a Base64-encoded version of this policy.

```
eyAizXhwaXJhdGlvbiI6IClYMDA3LTEyLTExVDEy0jAw0jAwLjAwMFoiLAogICJjb25kaXR  
pb25zIjogWwogICAgeyJidWNrZXQi0iAiam9obnNtaRoIn0sCiAgICBbInN0YXJ0cy13aXRoIiwgIiRrZXkiLC  
AiadXNlcLAogICAgeyJhY2wi0iAicHVibG1jLXJ1YWQifSwKICAgIHsic3VjY2Vzc19hY3Rp  
b25fcmlVkaXJ1Y3Qi0iAiaHR0cDovL2pC5zMy5hbWF6b25hd3MuY29tL25ld19wb3N0Lmh0bWwifSwK  
ICAgIFsiZXEilCAiJENvbnRlbnQtVHlwZSIisICJ0ZXh0L2h0CAgI  
IHsieC1hbXotbWV0YS11dWlkIjogIjE0MzY1MTIzNjUxMjc0In0sCiAgICBbInN0YXJ0cy13aXRoI  
iwgIiR4LWFtei1tIsICIiXQogIF0KfQo=
```

Using your credentials, create a signature. For example, qA7FWXKq6VvU68lI9KdveT1cWgF= is the signature for the preceding policy document.

The following form supports a POST request to the DOC-EXAMPLE-BUCKET bucket that uses this policy.

```
<html>
```

```
<head>
  ...
  <meta http-equiv="Content-Type" content="text/html; charset=UTF-8" />
  ...
</head>
<body>
  ...
<form action="https://DOC-EXAMPLE-BUCKET.s3.us-west-1.amazonaws.com/" method="post"
enctype="multipart/form-data">
  Key to upload: <input type="input" name="key" value="user/eric/" /><br />
  <input type="hidden" name="acl" value="public-read" />
  <input type="hidden" name="success_action_redirect" value="https://
awsexamplebucket1.s3.us-west-1.amazonaws.com/new_post.html" />
  <input type="hidden" name="Content-Type" value="text/html" />
  <input type="hidden" name="x-amz-meta-uuid" value="14365123651274" />
  Tags for File: <input type="input" name="x-amz-meta-tag" value="" /><br />
  <input type="hidden" name="AWSAccessKeyId" value="AKIAIOSFODNN7EXAMPLE" />
  <input type="hidden" name="Policy" value="POLICY" />
  <input type="hidden" name="Signature" value="SIGNATURE" />
  Entry: <textarea name="file" cols="60" rows="10">

Your blog post goes here.

</textarea><br />
<!-- The elements after this will be ignored --&gt;
&lt;input type="submit" name="submit" value="Upload to Amazon S3" /&gt;
&lt;/form&gt;
...
&lt;/html&gt;</pre>
```

Sample request

This request assumes that the image uploaded is 117,108 bytes; the image data is not included.

```

POST with adobe flash

This section describes how to use POST with Adobe Flash.

Adobe flash player security

By default, the Adobe Flash Player security model prohibits Adobe Flash Players from making network connections to servers outside the domain that serves the SWF file.

To override the default, you must upload a publicly readable crossdomain.xml file to the bucket that will accept POST uploads. The following is a sample crossdomain.xml file.

```
<?xml version="1.0"?>
<!DOCTYPE cross-domain-policy SYSTEM
"http://www.macromedia.com/xml/dtds/cross-domain-policy.dtd">
<cross-domain-policy>
<allow-access-from domain="*" secure="false" />
</cross-domain-policy>
```

Note

For more information about the Adobe Flash security model, go to the [Adobe website](#).

Adding the crossdomain.xml file to your bucket allows any Adobe Flash Player to connect to the crossdomain.xml file within your bucket; however, it does not grant access to the actual Amazon S3 bucket.

Adobe flash considerations

The FileReference API in Adobe Flash adds the `Filename` form field to the POST request. When you build Adobe Flash applications that upload to Amazon S3 by using the FileReference API action, include the following condition in your policy:

```
['starts-with', '$Filename', '']
```

Some versions of the Adobe Flash Player do not properly handle HTTP responses that have an empty body. To configure POST to return a response that does not have an empty body, set `success_action_status` to 201. Amazon S3 will then return an XML document with a 201 status code. For information about the content of the XML document, see [POST Object](#). For information about form fields, see [HTML form fields](#).

Best practices design patterns: optimizing Amazon S3 performance

Your applications can easily achieve thousands of transactions per second in request performance when uploading and retrieving storage from Amazon S3. Amazon S3 automatically scales to high request rates. For example, your application can achieve at least 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per partitioned Amazon S3 prefix. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by using parallelization. For example, if you create 10 prefixes in an Amazon S3 bucket to parallelize reads, you could scale your read performance to 55,000 read requests per second. Similarly, you can scale write operations by writing to multiple prefixes. The scaling, in the case of both read and write operations, happens gradually and is not instantaneous. While Amazon S3 is scaling to your new higher request rate, you may see some 503 (Slow Down) errors. These errors will dissipate when the scaling is complete. For more information about creating and using prefixes, see [Organizing objects using prefixes](#).

Some data lake applications on Amazon S3 scan millions or billions of objects for queries that run over petabytes of data. These data lake applications achieve single-instance transfer rates that maximize the network interface use for their [Amazon EC2](#) instance, which can be up to 100 Gb/s on a single instance. These applications then aggregate throughput across multiple instances to get multiple terabits per second.

Other applications are sensitive to latency, such as social media messaging applications. These applications can achieve consistent small object latencies (and first-byte-out latencies for larger objects) of roughly 100–200 milliseconds.

Other AWS services can also help accelerate performance for different application architectures. For example, if you want higher transfer rates over a single HTTP connection or single-digit millisecond latencies, use [Amazon CloudFront](#) or [Amazon ElastiCache](#) for caching with Amazon S3.

Additionally, if you want fast data transport over long distances between a client and an S3 bucket, use [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#). Transfer Acceleration uses the globally distributed edge locations in CloudFront to accelerate data transport over geographical distances. If your Amazon S3 workload uses server-side encryption with AWS KMS, see [AWS KMS Limits](#) in the AWS Key Management Service Developer Guide for information about the request rates supported for your use case.

The following topics describe best practice guidelines and design patterns for optimizing performance for applications that use Amazon S3. Refer to the [Performance Guidelines for Amazon S3](#) and [Performance Design Patterns for Amazon S3](#) for the most current information about performance optimization for Amazon S3.

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [What is S3 Express One Zone?](#) and [Directory buckets](#).

Topics

- [Performance Guidelines for Amazon S3](#)
- [Performance Design Patterns for Amazon S3](#)

Performance Guidelines for Amazon S3

When building applications that upload and retrieve objects from Amazon S3, follow our best practices guidelines to optimize performance. We also offer more detailed [Performance Design Patterns](#).

To obtain the best performance for your application on Amazon S3, we recommend the following guidelines.

Topics

- [Measure Performance](#)
- [Scale Storage Connections Horizontally](#)
- [Use Byte-Range Fetches](#)
- [Retry Requests for Latency-Sensitive Applications](#)
- [Combine Amazon S3 \(Storage\) and Amazon EC2 \(Compute\) in the Same AWS Region](#)
- [Use Amazon S3 Transfer Acceleration to Minimize Latency Caused by Distance](#)
- [Use the Latest Version of the AWS SDKs](#)

Measure Performance

When optimizing performance, look at network throughput, CPU, and DRAM requirements. Depending on the mix of demands for these different resources, it might be worth evaluating different [Amazon EC2](#) instance types. For more information about instance types, see [Instance Types](#) in the *Amazon EC2 User Guide for Linux Instances*.

It's also helpful to look at DNS lookup time, latency, and data transfer speed using HTTP analysis tools when measuring performance.

To understand the performance requirements and optimize the performance of your application, you can also monitor the 503 error responses that you receive. Monitoring certain performance metrics may incur additional expenses. For more information, see [Amazon S3 pricing](#).

Monitor the number of 503 (Slow Down) status error responses

To monitor the number of 503 status error responses that you get, you can use one of the following options:

- Use Amazon CloudWatch request metrics for Amazon S3. The CloudWatch request metrics include a metric for 5xx status responses. For more information about CloudWatch request metrics, see [Monitoring metrics with Amazon CloudWatch](#).
- Use the 503 (Service Unavailable) error count available in the advanced metrics section of Amazon S3 Storage Lens. For more information, see [Using S3 Storage Lens metrics to improve performance](#).
- Use Amazon S3 server access logging. With server access logging, you can filter and review all requests that receive 503 (Internal Error) responses. You can also use Amazon Athena to parse logs. For more information about server access logging, see [Logging requests with server access logging](#).

By monitoring the number of HTTP 503 status error code, you can often gain valuable insights into which prefixes, keys, or buckets are getting the most throttling requests.

Scale Storage Connections Horizontally

Spreading requests across many connections is a common design pattern to horizontally scale performance. When you build high performance applications, think of Amazon S3 as a very large distributed system, not as a single network endpoint like a traditional storage server. You can achieve the best performance by issuing multiple concurrent requests to Amazon S3. Spread

these requests over separate connections to maximize the accessible bandwidth from Amazon S3. Amazon S3 doesn't have any limits for the number of connections made to your bucket.

Use Byte-Range Fetches

Using the Range HTTP header in a [GET Object](#) request, you can fetch a byte-range from an object, transferring only the specified portion. You can use concurrent connections to Amazon S3 to fetch different byte ranges from within the same object. This helps you achieve higher aggregate throughput versus a single whole-object request. Fetching smaller ranges of a large object also allows your application to improve retry times when requests are interrupted. For more information, see [Downloading objects](#).

Typical sizes for byte-range requests are 8 MB or 16 MB. If objects are PUT using a multipart upload, it's a good practice to GET them in the same part sizes (or at least aligned to part boundaries) for best performance. GET requests can directly address individual parts; for example, `GET ?partNumber=N`.

Retry Requests for Latency-Sensitive Applications

Aggressive timeouts and retries help drive consistent latency. Given the large scale of Amazon S3, if the first request is slow, a retried request is likely to take a different path and quickly succeed. The AWS SDKs have configurable timeout and retry values that you can tune to the tolerances of your specific application.

Combine Amazon S3 (Storage) and Amazon EC2 (Compute) in the Same AWS Region

Although S3 bucket names are [globally unique](#), each bucket is stored in a Region that you select when you create the bucket. To optimize performance, we recommend that you access the bucket from Amazon EC2 instances in the same AWS Region when possible. This helps reduce network latency and data transfer costs.

For more information about data transfer costs, see [Amazon S3 Pricing](#).

Use Amazon S3 Transfer Acceleration to Minimize Latency Caused by Distance

[Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#) manages fast, easy, and secure transfers of files over long geographic distances between the client and an S3 bucket.

Transfer Acceleration takes advantage of the globally distributed edge locations in [Amazon CloudFront](#). As the data arrives at an edge location, it is routed to Amazon S3 over an optimized network path. Transfer Acceleration is ideal for transferring gigabytes to terabytes of data regularly across continents. It's also useful for clients that upload to a centralized bucket from all over the world.

You can use the [Amazon S3 Transfer Acceleration Speed Comparison tool](#) to compare accelerated and non-accelerated upload speeds across Amazon S3 Regions. The Speed Comparison tool uses multipart uploads to transfer a file from your browser to various Amazon S3 Regions with and without using Amazon S3 Transfer Acceleration.

Use the Latest Version of the AWS SDKs

The AWS SDKs provide built-in support for many of the recommended guidelines for optimizing Amazon S3 performance. The SDKs provide a simpler API for taking advantage of Amazon S3 from within an application and are regularly updated to follow the latest best practices. For example, the SDKs include logic to automatically retry requests on HTTP 503 errors and are investing in code to respond and adapt to slow connections.

The SDKs also provide the [Transfer Manager](#), which automates horizontally scaling connections to achieve thousands of requests per second, using byte-range requests where appropriate. It's important to use the latest version of the AWS SDKs to obtain the latest performance optimization features.

You can also optimize performance when you are using HTTP REST API requests. When using the REST API, you should follow the same best practices that are part of the SDKs. Allow for timeouts and retries on slow requests, and multiple connections to allow fetching of object data in parallel. For information about using the REST API, see the [Amazon Simple Storage Service API Reference](#).

Performance Design Patterns for Amazon S3

When designing applications to upload and retrieve objects from Amazon S3, use our best practices design patterns for achieving the best performance for your application. We also offer [Performance Guidelines](#) for you to consider when planning your application architecture.

To optimize performance, you can use the following design patterns.

Topics

- [Using Caching for Frequently Accessed Content](#)

- [Timeouts and Retries for Latency-Sensitive Applications](#)
- [Horizontal Scaling and Request Parallelization for High Throughput](#)
- [Using Amazon S3 Transfer Acceleration to Accelerate Geographically Disparate Data Transfers](#)

Using Caching for Frequently Accessed Content

Many applications that store data in Amazon S3 serve a “working set” of data that is repeatedly requested by users. If a workload is sending repeated GET requests for a common set of objects, you can use a cache such as [Amazon CloudFront](#), [Amazon ElastiCache](#), or [AWS Elemental MediaStore](#) to optimize performance. Successful cache adoption can result in low latency and high data transfer rates. Applications that use caching also send fewer direct requests to Amazon S3, which can help reduce request costs.

Amazon CloudFront is a fast content delivery network (CDN) that transparently caches data from Amazon S3 in a large set of geographically distributed points of presence (PoPs). When objects might be accessed from multiple Regions, or over the internet, CloudFront allows data to be cached close to the users that are accessing the objects. This can result in high performance delivery of popular Amazon S3 content. For information about CloudFront, see the [Amazon CloudFront Developer Guide](#).

Amazon ElastiCache is a managed, in-memory cache. With ElastiCache, you can provision Amazon EC2 instances that cache objects in memory. This caching results in orders of magnitude reduction in GET latency and substantial increases in download throughput. To use ElastiCache, you modify application logic to both populate the cache with hot objects and check the cache for hot objects before requesting them from Amazon S3. For examples of using ElastiCache to improve Amazon S3 GET performance, see the blog post [Turbocharge Amazon S3 with Amazon ElastiCache for Redis](#).

AWS Elemental MediaStore is a caching and content distribution system specifically built for video workflows and media delivery from Amazon S3. MediaStore provides end-to-end storage APIs specifically for video, and is recommended for performance-sensitive video workloads. For information about MediaStore, see the [AWS Elemental MediaStore User Guide](#).

Timeouts and Retries for Latency-Sensitive Applications

There are certain situations where an application receives a response from Amazon S3 indicating that a retry is necessary. Amazon S3 maps bucket and object names to the object data associated with them. If an application generates high request rates (typically sustained rates of over 5,000 requests per second to a small number of objects), it might receive HTTP 503 *slowdown* responses.

If these errors occur, each AWS SDK implements automatic retry logic using exponential backoff. If you are not using an AWS SDK, you should implement retry logic when receiving the HTTP 503 error. For information about back-off techniques, see [Error Retries and Exponential Backoff in AWS](#) in the *Amazon Web Services General Reference*.

Amazon S3 automatically scales in response to sustained new request rates, dynamically optimizing performance. While Amazon S3 is internally optimizing for a new request rate, you will receive HTTP 503 request responses temporarily until the optimization completes. After Amazon S3 internally optimizes performance for the new request rate, all requests are generally served without retries.

For latency-sensitive applications, Amazon S3 advises tracking and aggressively retrying slower operations. When you retry a request, we recommend using a new connection to Amazon S3 and performing a fresh DNS lookup.

When you make large variably sized requests (for example, more than 128 MB), we advise tracking the throughput being achieved and retrying the slowest 5 percent of the requests. When you make smaller requests (for example, less than 512 KB), where median latencies are often in the tens of milliseconds range, a good guideline is to retry a GET or PUT operation after 2 seconds. If additional retries are needed, the best practice is to back off. For example, we recommend issuing one retry after 2 seconds and a second retry after an additional 4 seconds.

If your application makes fixed-size requests to Amazon S3, you should expect more consistent response times for each of these requests. In this case, a simple strategy is to identify the slowest 1 percent of requests and to retry them. Even a single retry is frequently effective at reducing latency.

If you are using AWS Key Management Service (AWS KMS) for server-side encryption, see [Limits](#) in the *AWS Key Management Service Developer Guide* for information about the request rates that are supported for your use case.

Horizontal Scaling and Request Parallelization for High Throughput

Amazon S3 is a very large distributed system. To help you take advantage of its scale, we encourage you to horizontally scale parallel requests to the Amazon S3 service endpoints. In addition to distributing the requests within Amazon S3, this type of scaling approach helps distribute the load over multiple paths through the network.

For high-throughput transfers, Amazon S3 advises using applications that use multiple connections to GET or PUT data in parallel. For example, this is supported by [Amazon S3 Transfer Manager](#)

in the AWS Java SDK, and most of the other AWS SDKs provide similar constructs. For some applications, you can achieve parallel connections by launching multiple requests concurrently in different application threads, or in different application instances. The best approach to take depends on your application and the structure of the objects that you are accessing.

You can use the AWS SDKs to issue GET and PUT requests directly rather than employing the management of transfers in the AWS SDK. This approach lets you tune your workload more directly, while still benefiting from the SDK's support for retries and its handling of any HTTP 503 responses that might occur. As a general rule, when you download large objects within a Region from Amazon S3 to [Amazon EC2](#), we suggest making concurrent requests for byte ranges of an object at the granularity of 8–16 MB. Make one concurrent request for each 85–90 MB/s of desired network throughput. To saturate a 10 Gb/s network interface card (NIC), you might use about 15 concurrent requests over separate connections. You can scale up the concurrent requests over more connections to saturate faster NICs, such as 25 Gb/s or 100 Gb/s NICs.

Measuring performance is important when you tune the number of requests to issue concurrently. We recommend starting with a single request at a time. Measure the network bandwidth being achieved and the use of other resources that your application uses in processing the data. You can then identify the bottleneck resource (that is, the resource with the highest usage), and hence the number of requests that are likely to be useful. For example, if processing one request at a time leads to a CPU usage of 25 percent, it suggests that up to four concurrent requests can be accommodated. Measurement is essential, and it is worth confirming resource use as the request rate is increased.

If your application issues requests directly to Amazon S3 using the REST API, we recommend using a pool of HTTP connections and re-using each connection for a series of requests. Avoiding per-request connection setup removes the need to perform TCP slow-start and Secure Sockets Layer (SSL) handshakes on each request. For information about using the REST API, see the [Amazon Simple Storage Service API Reference](#).

Finally, it's worth paying attention to DNS and double-checking that requests are being spread over a wide pool of Amazon S3 IP addresses. DNS queries for Amazon S3 cycle through a large list of IP endpoints. But caching resolvers or application code that reuses a single IP address do not benefit from address diversity and the load balancing that follows from it. Network utility tools such as the netstat command line tool can show the IP addresses being used for communication with Amazon S3, and we provide guidelines for DNS configurations to use. For more information about these guidelines, see [Making requests](#).

Using Amazon S3 Transfer Acceleration to Accelerate Geographically Disparate Data Transfers

[Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#) is effective at minimizing or eliminating the latency caused by geographic distance between globally dispersed clients and a regional application using Amazon S3. Transfer Acceleration uses the globally distributed edge locations in CloudFront for data transport. The AWS edge network has points of presence in more than 50 locations. Today, it is used to distribute content through CloudFront and to provide rapid responses to DNS queries made to [Amazon Route 53](#).

The edge network also helps to accelerate data transfers into and out of Amazon S3. It is ideal for applications that transfer data across or between continents, have a fast internet connection, use large objects, or have a lot of content to upload. As the data arrives at an edge location, data is routed to Amazon S3 over an optimized network path. In general, the farther away you are from an Amazon S3 Region, the higher the speed improvement you can expect from using Transfer Acceleration.

You can set up Transfer Acceleration on new or existing buckets. You can use a separate Amazon S3 Transfer Acceleration endpoint to use the AWS edge locations. The best way to test whether Transfer Acceleration helps client request performance is to use the [Amazon S3 Transfer Acceleration Speed Comparison tool](#). Network configurations and conditions vary from time to time and from location to location. So you are charged only for transfers where Amazon S3 Transfer Acceleration can potentially improve your upload performance. For information about using Transfer Acceleration with different AWS SDKs, see [Enabling and using S3 Transfer Acceleration](#).

What is Amazon S3 on Outposts?

AWS Outposts is a fully managed service that offers the same AWS infrastructure, AWS services, APIs, and tools to virtually any data center, co-location space, or on-premises facility for a truly consistent hybrid experience. AWS Outposts is ideal for workloads that require low-latency access to on-premises systems, local data processing, data residency, and migration of applications with local system interdependencies. For more information, see [What is AWS Outposts?](#) in the *AWS Outposts User Guide*.

With Amazon S3 on Outposts, you can create S3 buckets on your Outposts and easily store and retrieve objects on premises. S3 on Outposts provides a new storage class, OUTPOSTS, which uses the Amazon S3 APIs and is designed to store data durably and redundantly across multiple devices and servers on your Outposts. You communicate with your Outposts bucket by using an access point and endpoint connection over a virtual private cloud (VPC).

You can use the same APIs and features on Outposts buckets as you do on Amazon S3, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API.

- [How S3 on Outposts works](#)
- [Features of S3 on Outposts](#)
- [Related services](#)
- [Accessing S3 on Outposts](#)
- [Paying for S3 on Outposts](#)
- [Next steps](#)

How S3 on Outposts works

S3 on Outposts is an object storage service that stores data as objects within buckets on your Outpost. An *object* is a data file and any metadata that describes the file. A *bucket* is a container for objects.

To store your data in S3 on Outposts, you first create a bucket. When you create the bucket, you specify a bucket name and the Outpost that will hold the bucket. To access your S3 on Outposts bucket and perform object operations, you next create and configure an access point. You must also create an endpoint to route requests to your access point.

Access points simplify data access for any AWS service or customer application that stores data in S3. Access points are named network endpoints that are attached to buckets and can be used to perform object operations, such as `GetObject` and `PutObject`. Each access point has distinct permissions and network controls.

You can create and manage your S3 on Outposts buckets, access points, and endpoints by using the AWS Management Console, AWS CLI, AWS SDKs, or REST API. To upload and manage objects in your S3 on Outposts bucket, you can use the AWS CLI, AWS SDKs, or REST API.

Regions

During AWS Outposts provisioning, you or AWS creates a service link connection that connects your Outpost back to your chosen AWS Region or Outposts home Region for bucket operations and telemetry. An Outpost relies on connectivity to the parent AWS Region. The Outposts rack is not designed for disconnected operations or environments with limited to no connectivity. For more information, see [Outpost connectivity to AWS Regions](#) in the *AWS Outposts User Guide*.

Buckets

A bucket is a container for objects stored in S3 on Outposts. You can store any number of objects in a bucket and can have up to 100 buckets per account per Outpost.

When you create a bucket, you enter a bucket name and choose the Outpost where the bucket will reside. After you create a bucket, you cannot change the bucket name or move the bucket to a different Outpost. Bucket names must follow [Amazon S3 bucket naming rules](#). In S3 on Outposts, bucket names are unique to an Outpost and AWS account. S3 on Outposts buckets require the `outpost-id`, `account-id`, and bucket name to identify them.

The following example shows the Amazon Resource Name (ARN) format for S3 on Outposts buckets. The ARN is comprised of the Region your Outpost is homed to, your Outpost account, the Outpost ID, and the bucket name.

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/bucket/bucket-name
```

Every object is contained in a bucket. You must use access points to access any object in an Outposts bucket. When you specify the bucket for object operations, you use the access point ARN or access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

The following example shows the access point ARN format for S3 on Outposts, which includes the `outpost-id`, `account-id`, and access point name:

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/accesspoint/accesspoint-name
```

For more information about buckets, see [Working with S3 on Outposts buckets](#).

Objects

Objects are the fundamental entities stored in S3 on Outposts. Objects consist of object data and metadata. The metadata is a set of name-value pairs that describe the object. These pairs include some default metadata, such as the date last modified, and standard HTTP metadata, such as `Content-Type`. You can also specify custom metadata at the time that the object is stored. An object is uniquely identified within a bucket by a [key \(or name\)](#).

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your objects never leave your Outpost and are not in an AWS Region. Because the AWS Management Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

Keys

An *object key (or key name)* is the unique identifier for an object within a bucket. Every object in a bucket has exactly one key. The combination of a bucket and object key uniquely identifies each object.

The following example shows the ARN format for S3 on Outposts objects, which includes the AWS Region code for the Region that the Outpost is homed to, AWS account ID, Outpost ID, bucket name, and object key:

```
arn:aws:s3-outposts:us-west-2:123456789012:outpost/ op-01ac5d28a6a232904/bucket/DOC-EXAMPLE-BUCKET1/object/myobject
```

For more information about object keys, see [Working with S3 on Outposts objects](#).

S3 Versioning

You can use S3 Versioning on Outposts buckets to keep multiple variants of an object in the same bucket. With S3 Versioning, you can preserve, retrieve, and restore every version of every object stored in your buckets. S3 Versioning helps you recover from unintended user actions and application failures.

For more information, see [Managing S3 Versioning for your S3 on Outposts bucket](#).

Version ID

When you enable S3 Versioning in a bucket, S3 on Outposts generates a unique version ID for each object added to the bucket. Objects that already existed in the bucket at the time that you enable versioning have a version ID of null. If you modify these (or any other) objects with other operations, such as [PutObject](#), the new objects get a unique version ID.

For more information, see [Managing S3 Versioning for your S3 on Outposts bucket](#).

Storage class and encryption

S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS). The S3 Outposts storage class is available only for objects stored in buckets on AWS Outposts. If you try to use other S3 storage classes with S3 on Outposts, S3 on Outposts returns the InvalidStorageClass error.

By default, objects stored in the S3 Outposts (OUTPOSTS) storage class are encrypted using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). For more information, see [Data encryption in S3 on Outposts](#).

Bucket policy

A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. Bucket policies are limited to 20 KB in size.

Bucket policies use JSON-based IAM policy language that is standard across AWS. You can use bucket policies to add or deny permissions for the objects in a bucket. Bucket policies allow or deny requests based on the elements in the policy. These elements can include the requester, S3 on Outposts actions, resources, and aspects or conditions of the request (for example, the IP address

used to make the request). For example, you can create a bucket policy that grants cross-account permissions to upload objects to an S3 on Outposts bucket while ensuring that the bucket owner has full control of the uploaded objects. For more information, see [Bucket policy examples](#).

In your bucket policy, you can use wildcard characters (*) in ARNs and other values to grant permissions to a subset of objects. For example, you can control access to groups of objects that begin with a common [prefix](#) or end with a given extension, such as .html.

S3 on Outposts access points

S3 on Outposts access points are named network endpoints with dedicated access policies that describe how data can be accessed using that endpoint. Access points simplify managing data access at scale for shared datasets in S3 on Outposts. Access points are attached to buckets that you can use to perform S3 object operations, such as GetObject and PutObject.

When you specify the bucket for object operations, you use the access point ARN or access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

Access points have distinct permissions and network controls that S3 on Outposts applies for any request that is made through that access point. Each access point enforces a customized access point policy that works in conjunction with the bucket policy that is attached to the underlying bucket.

For more information, see [Accessing your S3 on Outposts buckets and objects](#).

Features of S3 on Outposts

Access management

S3 on Outposts provides features for auditing and managing access to your buckets and objects. By default, S3 on Outposts buckets and the objects in them are private. You have access only to the S3 on Outposts resources that you create.

To grant granular resource permissions that support your specific use case or to audit the permissions of your S3 on Outposts resources, you can use the following features.

- [S3 Block Public Access](#) – Block public access to buckets and objects. For buckets on Outposts, Block Public Access is always enabled by default.

- [AWS Identity and Access Management \(IAM\)](#) – IAM is a web service that helps you securely control access to AWS resources, including your S3 on Outposts resources. With IAM, you can centrally manage permissions that control which AWS resources users can access. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- [S3 on Outposts access points](#) – Manage data access for shared datasets in S3 on Outposts. Access points are named network endpoints with dedicated access policies. Access points are attached to buckets and can be used to perform object operations, such as GetObject and PutObject.
- [Bucket policies](#) – Use IAM-based policy language to configure resource-based permissions for your S3 buckets and the objects in them.
- [AWS Resource Access Manager \(AWS RAM\)](#) – Securely share your S3 on Outposts capacity across AWS accounts, within your organization or organizational units (OUs) in AWS Organizations.

Storage logging and monitoring

S3 on Outposts provides logging and monitoring tools that you can use to monitor and control how your S3 on Outposts resources are being used. For more information, see [Monitoring tools](#).

- [Amazon CloudWatch metrics for S3 on Outposts](#) – Track the operational health of your resources and understand your capacity availability.
- [Amazon CloudWatch Events events for S3 on Outposts](#) – Create a rule for any S3 on Outposts API event to receive notifications through all supported CloudWatch Events targets, including Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), and AWS Lambda.
- [AWS CloudTrail logs for S3 on Outposts](#) – Record actions taken by a user, a role, or an AWS service in S3 on Outposts. CloudTrail logs provide you with detailed API tracking for S3 bucket-level and object-level operations.

Strong consistency

S3 on Outposts provides strong read-after-write consistency for PUT and DELETE requests of objects in your S3 on Outposts bucket in all AWS Regions. This behavior applies to both writes of new objects and to PUT requests that overwrite existing objects and to DELETE requests. In addition, S3 on Outposts object tags and object metadata (for example, the HEAD object) are strongly consistent. For more information, see [Amazon S3 data consistency model](#).

Related services

After you load your data into S3 on Outposts, you can use it with other AWS services. The following are the services that you might use most frequently:

- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#) – Provides secure and scalable computing capacity in the AWS Cloud. Using Amazon EC2 lessens your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage.
- [Amazon Elastic Block Store \(Amazon EBS\) on Outposts](#) – Use Amazon EBS local snapshots on Outposts to store snapshots of volumes on an Outpost locally in S3 on Outposts.
- [Amazon Relational Database Service \(Amazon RDS\) on Outposts](#) – Use Amazon RDS local backups to store your Amazon RDS backups locally on your Outpost.
- [AWS DataSync](#) – Automate transferring data between your Outposts and AWS Regions, choosing what to transfer, when to transfer, and how much network bandwidth to use. S3 on Outposts is integrated with AWS DataSync. For on-premises applications that require high-throughput local processing, S3 on Outposts provides on-premises object storage to minimize data transfers and buffer from network variations, while providing you the ability to easily transfer data between Outposts and AWS Regions.

Accessing S3 on Outposts

You can work with S3 on Outposts in any of the following ways:

AWS Management Console

The console is a web-based user interface for managing S3 on Outposts and AWS resources. If you've signed up for an AWS account, you can access S3 on Outposts by signing into the AWS Management Console and choosing **S3** from the AWS Management Console home page. Then, choose **Outposts buckets** from the left navigation pane.

AWS Command Line Interface

You can use the AWS command line tools to issue commands or build scripts at your system's command line to perform AWS (including S3) tasks.

The [AWS Command Line Interface \(AWS CLI\)](#) provides commands for a broad set of AWS services. The AWS CLI is supported on Windows, macOS, and Linux. To get started, see the [AWS Command Line Interface User Guide](#). For more information about the commands that you can use with S3 on Outposts, see [s3api](#), [s3control](#), and [s3outposts](#) in the *AWS CLI Command Reference*.

AWS SDKs

AWS provides SDKs (software development kits) that consist of libraries and sample code for various programming languages and platforms (Java, Python, Ruby, .NET, iOS, Android, and so on). The AWS SDKs provide a convenient way to create programmatic access to S3 on Outposts and AWS. Because S3 on Outposts uses the same SDKs as Amazon S3, S3 on Outposts provides a consistent experience using the same S3 APIs, automation, and tools.

S3 on Outposts is a REST service. You can send requests to S3 on Outposts by using the AWS SDK libraries, which wrap the underlying REST API and simplify your programming tasks. For example, the SDKs take care of tasks such as calculating signatures, cryptographically signing requests, managing errors, and retrying requests automatically. For information about the AWS SDKs, including how to download and install them, see [Tools to Build on AWS](#).

Paying for S3 on Outposts

You can purchase a variety of AWS Outposts rack configurations featuring a combination of Amazon EC2 instance types, Amazon EBS General Purpose solid state drive (SSD) volumes (gp2), and S3 on Outposts. Pricing includes delivery, installation, infrastructure service maintenance, and software patches and upgrades.

For more information, see [AWS Outposts rack pricing](#).

Next steps

For more information about working with S3 on Outposts, see the following topics:

- [Setting up your Outpost](#)
- [How is Amazon S3 on Outposts different from Amazon S3?](#)
- [Getting started with Amazon S3 on Outposts](#)
- [Networking for S3 on Outposts](#)
- [Working with S3 on Outposts buckets](#)
- [Working with S3 on Outposts objects](#)

- [Security in S3 on Outposts](#)
- [Managing S3 on Outposts storage](#)
- [Developing with Amazon S3 on Outposts](#)

Setting up your Outpost

To get started with Amazon S3 on Outposts, you will need an Outpost with Amazon S3 capacity deployed at your facility. For information about options for ordering an Outpost and S3 capacity, see [AWS Outposts](#). To check if your Outposts has S3 capacity on it, you can use the [ListOutpostsWithS3](#) API call. For specifications and to see how S3 on Outposts is different than Amazon S3, see [How is Amazon S3 on Outposts different from Amazon S3?](#)

For more information, see the following topics.

Topics

- [Order a new Outpost](#)

Order a new Outpost

If you need to order a new Outpost with S3 capacity, see [AWS Outposts rack pricing](#) to understand the capacity options for Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic Block Store (Amazon EBS), and Amazon S3.

After you select your configuration, follow the steps in [Create an Outpost and order Outpost capacity](#) in the *AWS Outposts User Guide*.

How is Amazon S3 on Outposts different from Amazon S3?

Amazon S3 on Outposts delivers object storage to your on-premises AWS Outposts environment. Using S3 on Outposts helps you to meet local processing, data residency, and demanding performance needs by keeping data close to on-premises applications. Because it uses Amazon S3 APIs and features, S3 on Outposts makes it easy to store, secure, tag, report on, and control access to the data on your Outposts and extend AWS infrastructure to your on-premises facility for a consistent hybrid experience.

For more information about how S3 on Outposts is unique, see the following topics.

Topics

- [S3 on Outposts specifications](#)
- [API operations supported by S3 on Outposts](#)
- [Amazon S3 features not supported by S3 on Outposts](#)
- [S3 on Outposts network requirements](#)

S3 on Outposts specifications

- The maximum Outposts bucket size is 50 TB.
- The maximum number of Outposts buckets is 100 per AWS account.
- Outposts buckets can be accessed only by using access points and endpoints.
- The maximum number of access points per Outposts bucket is 10.
- Access point policies are limited to 20 KB in size.
- The Outpost owner can manage access within your organization in AWS Organizations by using AWS Resource Access Manager. All accounts that need access to the Outpost must be within the same organization as the owner account in AWS Organizations.
- The S3 on Outposts bucket owner account is always the owner of all objects in the bucket.
- Only the S3 on Outposts bucket owner account can perform operations on the bucket.
- Object size limitations are consistent with Amazon S3.
- All objects stored on S3 on Outposts are stored in the OUTPOSTS storage class.
- By default, all objects stored in the OUTPOSTS storage class are stored by using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). You can also explicitly choose to store objects by using server-side encryption with customer-provided encryption keys (SSE-C).
- If there is not enough space to store an object on your Outpost, the API returns an insufficient capacity exception (ICE).

API operations supported by S3 on Outposts

For a list of API operations supported by S3 on Outposts, see [Amazon S3 on Outposts API operations](#).

Amazon S3 features not supported by S3 on Outposts

The following Amazon S3 features are currently not supported by Amazon S3 on Outposts. Any attempts to use them are rejected.

- Access control lists (ACLs)
- Cross-origin resource sharing (CORS)
- S3 Batch Operations
- S3 Inventory reports
- Changing the default bucket encryption
- Public buckets
- Multi-factor authentication (MFA) delete
- S3 Lifecycle transitions (aside from object deletion and stopping incomplete multipart uploads)
- S3 Object Lock legal hold
- Object Lock retention
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- S3 Replication Time Control (S3 RTC)
- Amazon CloudWatch request metrics
- Metrics configuration
- Transfer Acceleration
- S3 Event Notifications
- Requester Pays buckets
- S3 Select
- AWS Lambda events
- Server access logging
- HTTP POST requests
- SOAP
- Website access

S3 on Outposts network requirements

- To route requests to an S3 on Outposts access point, you must create and configure an S3 on Outposts endpoint. The following limits apply to endpoints for S3 on Outposts:
 - Each virtual private cloud (VPC) on an Outpost can have one associated endpoint, and you can have up to 100 endpoints per Outpost.

- You can map multiple access points to the same endpoint.
- You can add endpoints only to VPCs with CIDR blocks in the subspaces of the following CIDR ranges:
 - 10.0.0.0/8
 - 172.16.0.0/12
 - 192.168.0.0/16
- You can create endpoints to an Outpost only from VPCs that have non-overlapping CIDR blocks.
- You can create an endpoint only from within its Outposts subnet.
- The subnet that you use to create an endpoint must contain four IP addresses for S3 on Outposts to use.
- If you specify the customer-owned IP address pool (CoIP pool), it must contain four IP addresses for S3 on Outposts to use.
- You can create only one endpoint per Outpost per VPC.

Getting started with Amazon S3 on Outposts

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API.

With Amazon S3 on Outposts, you can use the Amazon S3 APIs and features, such as object storage, access policies, encryption, and tagging, on AWS Outposts as you do on Amazon S3. For information about S3 on Outposts, see [What is Amazon S3 on Outposts?](#)

Topics

- [Setting up IAM with S3 on Outposts](#)
- [Getting started by using the AWS Management Console](#)
- [Getting started by using the AWS CLI and SDK for Java](#)

Setting up IAM with S3 on Outposts

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon S3 on Outposts resources. IAM is an AWS service that you can use with no additional charge. By default, users don't have permissions for S3 on Outposts resources and operations. To grant access permissions for S3 on Outposts resources and API operations, you can use IAM to create [users](#), [groups](#), or [roles](#) and attach permissions.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

In addition to IAM identity-based policies, S3 on Outposts supports both bucket and access point policies. Bucket policies and access point policies are [resource-based policies](#) that are attached to the S3 on Outposts resource.

- A bucket policy is attached to the bucket and allows or denies requests to the bucket and the objects in it based on the elements in the policy.
- In contrast, an access point policy is attached to the access point and allows or denies requests to the access point.

The access point policy works with the bucket policy that is attached to the underlying S3 on Outposts bucket. For an application or user to access objects in an S3 on Outposts bucket through

an S3 on Outposts access point, both the access point policy and the bucket policy must permit the request.

Restrictions that you include in an access point policy apply only to requests made through that access point. For example, if an access point is attached to a bucket, you can't use the access point policy to allow or deny requests that are made directly to the bucket. However, restrictions that you apply to a bucket policy can allow or deny requests made directly to the bucket or through the access point.

In an IAM policy or a resource-based policy, you define which S3 on Outposts actions are allowed or denied. S3 on Outposts actions correspond to specific S3 on Outposts API operations. S3 on Outposts actions use the `s3-outposts:` namespace prefix. Requests made to the S3 on Outposts control API in an AWS Region and requests made to the object API endpoints on the Outpost are authenticated by using IAM and authorized against the `s3-outposts:` namespace prefix. To work with S3 on Outposts, configure your IAM users and authorize them against the `s3-outposts:` IAM namespace.

For more information, see [Actions, resources, and condition keys for Amazon S3 on Outposts](#) in the [Service Authorization Reference](#).

Note

- Access control lists (ACLs) are not supported by S3 on Outposts.
- S3 on Outposts defaults to the bucket owner as object owner to help ensure that the owner of a bucket can't be prevented from accessing or deleting objects.
- S3 on Outposts always has S3 Block Public Access enabled to help ensure that objects can never have public access.

For more information about setting up IAM for S3 on Outposts, see the following topics.

Topics

- [Principals for S3 on Outposts policies](#)
- [Resource ARNs for S3 on Outposts](#)
- [Example policies for S3 on Outposts](#)
- [Permissions for S3 on Outposts endpoints](#)

- [Service-linked roles for S3 on Outposts](#)

Principals for S3 on Outposts policies

When you create a resource-based policy to grant access to your S3 on Outposts bucket, you must use the `Principal` element to specify the person or application that can make a request for an action or operation on that resource. For S3 on Outposts policies, you can use one of the following principals:

- An AWS account
- An IAM user
- An IAM role
- All principals, by specifying a wildcard character (*) in a policy that uses a `Condition` element to limit access to a specific IP range

Important

You can't write a policy for an S3 on Outposts bucket that uses a wildcard character (*) in the `Principal` element unless the policy also includes a `Condition` that limits access to a specific IP address range. This restriction helps ensure that there is no public access to your S3 on Outposts bucket. For an example, see [Example policies for S3 on Outposts](#).

For more information about the `Principal` element, see [AWS JSON policy elements: Principal](#) in the *IAM User Guide*.

Resource ARNs for S3 on Outposts

Amazon Resource Names (ARNs) for S3 on Outposts contain the Outpost ID in addition to the AWS Region that the Outpost is homed to, the AWS account ID, and the resource name. To access and perform actions on your Outposts buckets and objects, you must use one of the ARN formats shown in the following table.

The `partition` value in the ARN refers to a group of AWS Regions. Each AWS account is scoped to one partition. The following are the supported partitions:

- aws – AWS Regions

- aws-us-gov – AWS GovCloud (US) Regions

S3 on Outposts ARN formats

Amazon S3 on Outposts ARN	ARN format	Example
Bucket ARN	<code>arn:<i>partition</i> :s3-outposts: <i>region</i>: <i>account_id</i> :outpost / <i>outpost_id</i> / bucket/<i>bucket_name</i></code>	<code>arn:aws:s3-outposts:us-west-2: 123456789012 :outpost/ op-01ac5d/28a6a232904 / bucket/DOC-EXAMPLE-BUCKET1</code>
Access point ARN	<code>arn:<i>partition</i> :s3-outposts: <i>region</i>: <i>account_id</i> :outpost / <i>outpost_id</i> /accesspoint/<i>accesspoint_name</i></code>	<code>arn:aws:s3-outposts:us-west-2: 123456789012 :outpost/ op-01ac5d/28a6a232904 /accesspoint/ access-point-name</code>
Object ARN	<code>arn:<i>partition</i> :s3-outposts: <i>region</i>: <i>account_id</i> :outpost / <i>outpost_id</i> / bucket/<i>bucket_name</i> / object/<i>object_key</i></code>	<code>arn:aws:s3-outposts:us-west-2: 123456789012 :outpost/ op-01ac5d/28a6a232904 / bucket/DOC-EXAMPLE-BUCKET1 /object/m yobject</code>
S3 on Outposts access point object ARN (used in policies)	<code>arn:<i>partition</i> :s3-outposts: <i>region</i>: <i>account_id</i> :outpost / <i>outpost_id</i> /accesspoint/<i>accesspoi</i></code>	<code>arn:aws:s3-outposts:us-west-2: 123456789012 :outpost/ op-01ac5d/28a6a232904 /accesspo</code>

Amazon S3 on Outposts ARN	ARN format	Example
	<i>nt_name / object/object_key</i>	<i>int/ access-point-name/object/myobject</i>
S3 on Outposts ARN	<i>arn:partition :s3-outposts:region:account_id :outpost / outpost_id</i>	<i>arn:aws:s3-outposts:us-west-2:123456789012:outpost/op-01ac5d28a6a232904</i>

Example policies for S3 on Outposts

Example : S3 on Outposts bucket policy with an AWS account principal

The following bucket policy uses an AWS account principal to grant access to an S3 on Outposts bucket. To use this bucket policy, replace the *user input placeholders* with your own information.

```
{
    "Version": "2012-10-17",
    "Id": "ExampleBucketPolicy1",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "123456789012"
            },
            "Action": "s3-outposts:*",
            "Resource": "arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket"
        }
    ]
}
```

Example : S3 on Outposts bucket policy with a wildcard principal (*) and condition key to limit access to a specific IP address range

The following bucket policy uses a wildcard principal (*) with the aws:SourceIp condition to limit access to a specific IP address range. To use this bucket policy, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Id": "ExampleBucketPolicy2",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Principal": { "AWS" : "*" },  
            "Action": "s3-outposts:*",  
            "Resource": "arn:aws:s3-  
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-  
bucket",  
            "Condition" : {  
                "IpAddress" : {  
                    "aws:SourceIp": "192.0.2.0/24"  
                },  
                "NotIpAddress" : {  
                    "aws:SourceIp": "198.51.100.0/24"  
                }  
            }  
        }  
    ]  
}
```

Permissions for S3 on Outposts endpoints

S3 on Outposts requires its own permissions in IAM to manage S3 on Outposts endpoint actions.

Note

- For endpoints that use the customer-owned IP address pool (CoIP pool) access type, you also must have permissions to work with IP addresses from your CoIP pool, as described in the following table.

- For shared accounts that access S3 on Outposts by using AWS Resource Access Manager, users in these shared accounts can't create their own endpoints on a shared subnet. If a user in a shared account wants to manage their own endpoints, the shared account must create its own subnet on the Outpost. For more information, see [the section called "Sharing S3 on Outposts".](#)

S3 on Outposts endpoint-related IAM permissions

Action	IAM permissions
CreateEndpoint	<p>s3-outposts:CreateEndpoint</p> <p>ec2:CreateNetworkInterface</p> <p>ec2:DescribeNetworkInterfaces</p> <p>ec2:DescribeVpcs</p> <p>ec2:DescribeSecurityGroups</p> <p>ec2:DescribeSubnets</p> <p>ec2:CreateTags</p> <p>iam:CreateServiceLinkedRole</p> <p>For endpoints that are using the on-premises customer-owned IP address pool (CoIP pool) access type, the following additional permissions are required:</p> <p>s3-outposts:CreateEndpoint</p> <p>ec2:DescribeCoipPools</p> <p>ec2:GetCoipPoolUsage</p> <p>ec2:AllocateAddress</p> <p>ec2:AssociateAddress</p>

Action	IAM permissions
	ec2:DescribeAddresses ec2:DescribeLocalGatewayRouteTableVpcAssociations
DeleteEndpoint	s3-outposts:DeleteEndpoint ec2:DeleteNetworkInterface ec2:DescribeNetworkInterfaces For endpoints that are using the on-premises customer-owned IP address pool (CoIP pool) access type, the following additional permissions are required: s3-outposts:DeleteEndpoint ec2:DisassociateAddress ec2:DescribeAddresses ec2:ReleaseAddress
ListEndpoints	s3-outposts>ListEndpoints

Note

You can use resource tags in an IAM policy to manage permissions.

Service-linked roles for S3 on Outposts

S3 on Outposts uses IAM service-linked roles to create some network resources on your behalf. For more information, see [Using service-linked roles for Amazon S3 on Outposts](#).

Getting started by using the AWS Management Console

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

To get started with S3 on Outposts by using the console, see the following topics. To get started by using the AWS CLI or AWS SDK for Java, see [Getting started by using the AWS CLI and SDK for Java](#).

Topics

- [Create a bucket, an access point, and an endpoint](#)
- [Next steps](#)

Create a bucket, an access point, and an endpoint

The following procedure shows you how to create your first bucket in S3 on Outposts. When you create a bucket using the console, you also create an access point and an endpoint associated with the bucket so that you can immediately begin storing objects in your bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose **Create Outposts bucket**.
4. For **Bucket name**, enter a Domain Name System (DNS)-compliant name for your bucket.

The bucket name must:

- Be unique within the AWS account, the Outpost, and the AWS Region that the Outpost is homed to.
- Be 3–63 characters long.

- Not contain uppercase characters.
- Start with a lowercase letter or number.

After you create the bucket, you can't change its name. For information about naming buckets, see [Bucket naming rules](#).

⚠ Important

Avoid including sensitive information such as account numbers in the bucket name.
The bucket name is visible in the URLs that point to the objects in the bucket.

5. For **Outpost**, choose the Outpost where you want the bucket to reside.
6. Under **Bucket Versioning**, set the S3 Versioning state for your S3 on Outposts bucket to one of the following options:
 - **Disable** (default) – The bucket remains unversioned.
 - **Enable** – Enables S3 Versioning for the objects in the bucket. All objects added to the bucket receive a unique version ID.

For more information about S3 Versioning, see [Managing S3 Versioning for your S3 on Outposts bucket](#).

7. (Optional) Add any **optional tags** that you would like to associate with the Outposts bucket. You can use tags to track criteria for individual projects or groups of projects, or to label your buckets by using cost-allocation tags.

By default, all objects stored in your Outposts bucket are stored by using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). You can also explicitly choose to store objects by using server-side encryption with customer-provided encryption keys (SSE-C). To change the encryption type, you must use the REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

8. In the **Outposts access point settings** section, enter the access point name.

S3 on Outposts access points simplify managing data access at scale for shared datasets in S3 on Outposts. Access points are named network endpoints that are attached to Outposts buckets that you can use to perform S3 object operations. For more information, see [Access points](#).

Access point names must be unique within the account for this Region and Outpost, and comply with the [Access points restrictions and limitations](#).

9. Choose the **VPC** for this Amazon S3 on Outposts access point.

If you don't have a VPC, choose **Create VPC**. For more information, see [Creating access points restricted to a virtual private cloud](#).

A virtual private cloud (VPC) enables you to launch AWS resources into a virtual network that you define. This virtual network closely resembles a traditional network that you would operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

10. (Optional for an existing VPC) Choose an **Endpoint subnet** for your endpoint.

A subnet is a range of IP addresses in your VPC. If you don't have the subnet that you want, choose **Create subnet**. For more information, see [Networking for S3 on Outposts](#).

11. (Optional for an existing VPC) Choose an **Endpoint security group** for your endpoint.

A [security group](#) acts as a virtual firewall to control inbound and outbound traffic.

12. (Optional for an existing VPC) Choose the **Endpoint access type**:

- **Private** – To be used with the VPC.
- **Customer owned IP** – To be used with a customer-owned IP address pool (CoIP pool) from within your on-premises network.

13. (Optional) Specify the **Outpost access point policy**. The console automatically displays the **Amazon Resource Name (ARN)** for the access point, which you can use in the policy.

14. Choose **Create Outposts bucket**.

 **Note**

It can take up to 5 minutes for your Outpost endpoint to be created and your bucket to be ready to use. To configure additional bucket settings, choose **View details**.

Next steps

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your objects never leave your Outpost and are not in an AWS Region. Because the AWS Management

Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

After you create an S3 on Outposts bucket, access point, and endpoint, you can use the AWS CLI or SDK for Java to upload an object to your bucket. For more information, see [Step 4: Upload an object to an S3 on Outposts bucket](#).

Getting started by using the AWS CLI and SDK for Java

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

To get started with S3 on Outposts, you must create a bucket, an access point, and an endpoint. Then, you can upload objects to your bucket. The following examples show you how to get started with S3 on Outposts by using the AWS CLI and SDK for Java. To get started by using the console, see [Getting started by using the AWS Management Console](#).

Topics

- [Step 1: Create a bucket](#)
- [Step 2: Create an access point](#)
- [Step 3: Create an endpoint](#)
- [Step 4: Upload an object to an S3 on Outposts bucket](#)

Step 1: Create a bucket

The following AWS CLI and SDK for Java examples show you how to create an S3 on Outposts bucket.

AWS CLI

Example

The following example creates an S3 on Outposts bucket (`s3-outposts:CreateBucket`) by using the AWS CLI. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control create-bucket --bucket example-outposts-bucket --outpost-id op-01ac5d28a6a232904
```

SDK for Java

Example

The following example creates an S3 on Outposts bucket (`s3-outposts:CreateBucket`) by using the SDK for Java.

```
import com.amazonaws.services.s3control.model.*;  
  
public String createBucket(String bucketName) {  
  
    CreateBucketRequest reqCreateBucket = new CreateBucketRequest()  
        .withBucket(bucketName)  
        .withOutpostId(OutpostId)  
        .withCreateBucketConfiguration(new CreateBucketConfiguration());  
  
    CreateBucketResult respCreateBucket =  
        s3ControlClient.createBucket(reqCreateBucket);  
    System.out.printf("CreateBucket Response: %s%n", respCreateBucket.toString());  
  
    return respCreateBucket.getBucketArn();  
}
```

Step 2: Create an access point

To access your Amazon S3 on Outposts bucket, you must create and configure an access point. These examples show how to create an access point by using the AWS CLI and the SDK for Java.

Access points simplify managing data access at scale for shared datasets in Amazon S3. Access points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 object operations, such as `GetObject` and `PutObject`. With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Access points support only virtual-host-style addressing.

AWS CLI

Example

The following AWS CLI example creates an access point for an Outposts bucket. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control create-access-point --account-id 123456789012
--name example-outposts-access-point --bucket "arn:aws:s3-
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-
bucket" --vpc-configuration VpcId=example-vpc-12345
```

SDK for Java

Example

The following SDK for Java example creates an access point for an Outposts bucket. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.services.s3control.model.*;

public String createAccessPoint(String bucketArn, String accessPointName) {

    CreateAccessPointRequest reqCreateAP = new CreateAccessPointRequest()
        .withAccountId(AccountId)
        .withBucket(bucketArn)
        .withName(accessPointName)
        .withVpcConfiguration(new VpcConfiguration().withVpcId("vpc-12345"));

    CreateAccessPointResult respCreateAP =
        s3ControlClient.createAccessPoint(reqCreateAP);
    System.out.printf("CreateAccessPoint Response: %s%n", respCreateAP.toString());

    return respCreateAP.getAccessPointArn();
}
```

Step 3: Create an endpoint

To route requests to an Amazon S3 on Outposts access point, you must create and configure an S3 on Outposts endpoint. In order to create an endpoint, you will need an active connection with your service link to your Outposts home region. Each virtual private cloud (VPC) on your Outpost can have one associated endpoint. For more information about endpoint quotas, see [S3 on Outposts network requirements](#). You must create an endpoint to be able to access your Outposts buckets and perform object operations. For more information, see [Endpoints](#).

These examples show you how to create an endpoint by using the AWS CLI and the SDK for Java. For more information about the permissions required to create and manage endpoints, see [Permissions for S3 on Outposts endpoints](#).

AWS CLI

Example

The following AWS CLI example creates an endpoint for an Outpost by using the VPC resource access type. The VPC is derived from the subnet. To run this command, replace the *user input placeholders* with your own information.

```
aws s3outposts create-endpoint --outpost-id op-01ac5d28a6a232904 --subnet-id
subnet-8c7a57c5 --security-group-id sg-ab19e0d1
```

The following AWS CLI example creates an endpoint for an Outpost by using the customer-owned IP address pool (CoIP pool) access type. To run this command, replace the *user input placeholders* with your own information.

```
aws s3outposts create-endpoint --outpost-id op-01ac5d28a6a232904 --subnet-id
subnet-8c7a57c5 --security-group-id sg-ab19e0d1 --access-type CustomerOwnedIp --
customer-owned-ipv4-pool ipv4pool-coip-12345678901234567
```

SDK for Java

Example

The following SDK for Java example creates an endpoint for an Outpost. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.services.s3outposts.AmazonS3Outposts;
```

```
import com.amazonaws.services.s3outposts.AmazonS3OutpostsClientBuilder;
import com.amazonaws.services.s3outposts.model.CreateEndpointRequest;
import com.amazonaws.services.s3outposts.model.CreateEndpointResult;

public void createEndpoint() {
    AmazonS3Outposts s3OutpostsClient = AmazonS3OutpostsClientBuilder
        .standard().build();

    CreateEndpointRequest createEndpointRequest = new CreateEndpointRequest()
        .withOutpostId("op-0d79779cef3c30a40")
        .withSubnetId("subnet-8c7a57c5")
        .withSecurityGroupId("sg-ab19e0d1")
        .withAccessType("CustomerOwnedIp")
        .withCustomerOwnedIpv4Pool("ipv4pool-coip-12345678901234567");
    // Use .withAccessType and .withCustomerOwnedIpv4Pool only when the access type
    // is
    // customer-owned IP address pool (CoIP pool)
    CreateEndpointResult createEndpointResult =
    s3OutpostsClient.createEndpoint(createEndpointRequest);
    System.out.println("Endpoint is created and its ARN is " +
    createEndpointResult.getEndpointArn());
}
```

Step 4: Upload an object to an S3 on Outposts bucket

Objects are the fundamental entities stored in Amazon S3 on Outposts. Every object is contained in a bucket. You must use access points to access any object in an Outpost bucket. When you specify the bucket for object operations, you use the access point Amazon Resource Name (ARN) or the access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

The following example shows the ARN format for S3 on Outposts access points, which includes the AWS Region code for the Region that the Outpost is homed to, the AWS account ID, the Outpost ID, and the access point name:

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/accesspoint/accesspoint-name
```

For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your

objects never leave your Outpost and are not in an AWS Region. Because the AWS Management Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

The following AWS CLI and AWS SDK for Java examples show you how to upload an object to an S3 on Outposts bucket by using an access point.

AWS CLI

Example

The following example puts an object named `sample-object.xml` into an S3 on Outposts bucket (`s3-outposts:PutObject`) by using the AWS CLI. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [put-object](#) in the *AWS CLI Reference*.

```
aws s3api put-object --bucket arn:aws:s3-
outposts:Region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-
outposts-access-point --key sample-object.xml --body sample-object.xml
```

SDK for Java

Example

The following example puts an object into an S3 on Outposts bucket by using the SDK for Java. To use this example, replace each *user input placeholder* with your own information. For more information, see [Uploading objects](#).

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.ObjectMetadata;
import com.amazonaws.services.s3.model.PutObjectRequest;

import java.io.File;

public class PutObject {
    public static void main(String[] args) {
        String accessPointArn = "*** access point ARN ***";
        String stringObjKeyName = "*** String object key name ***";
```

```
String fileObjKeyName = "*** File object key name ***";
String fileName = "*** Path to file to upload ***;

try {
    // This code expects that you have AWS credentials set up per:
    // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-
credentials.html
    AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
        .enableUseArnRegion()
        .build();

    // Upload a text string as a new object.
    s3Client.putObject(accessPointArn, stringObjKeyName, "Uploaded String
Object");

    // Upload a file as a new object with ContentType and title specified.
    PutObjectRequest request = new PutObjectRequest(accessPointArn,
fileObjKeyName, new File(fileName));
    ObjectMetadata metadata = new ObjectMetadata();
    metadata.setContentType("plain/text");
    metadata.addUserMetadata("title", "someTitle");
    request.setMetadata(metadata);
    s3Client.putObject(request);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Networking for S3 on Outposts

You can use Amazon S3 on Outposts to store and retrieve objects on-premises for applications that require local data access, data processing, and data residency. This section describes the networking requirements for accessing S3 on Outposts.

Topics

- [Choosing your networking access type](#)
- [Accessing your S3 on Outposts buckets and objects](#)
- [Cross-account elastic network interfaces](#)

Choosing your networking access type

You can access S3 on Outposts from within a VPC or from your on-premises network. You communicate with your Outpost bucket by using an access point and endpoint connection. This connection keeps traffic between your VPC and your S3 on Outposts buckets within the AWS network. When you create an endpoint, you must specify the endpoint access type as either `Private` (for VPC routing) or `CustomerOwnedIp` (for a customer-owned IP address pool [CoIP pool]).

- `Private` (for VPC routing) – If you don't specify the access type, S3 on Outposts uses `Private` by default. With the `Private` access type, instances in your VPC don't require public IP addresses to communicate with resources in your Outpost. You can work with S3 on Outposts from within a VPC. This type of endpoint is accessible from your on-premises network through direct VPC routing. For more information, see [Local gateway route tables](#) in the *AWS Outposts User Guide*.
- `CustomerOwnedIp` (for CoIP pool) – If you don't default to the `Private` access type and choose `CustomerOwnedIp`, you must specify an IP address range. You can use this access type to work with S3 on Outposts from both your on-premises network and within a VPC. When accessing S3 on Outposts within a VPC, your traffic is limited to the bandwidth of the local gateway.

Accessing your S3 on Outposts buckets and objects

To access your S3 on Outposts buckets and objects, you must have the following:

- An access point for the VPC.
- An endpoint for the same VPC.
- An active connection between your Outpost and your AWS Region. For more information about how to connect your Outpost to a Region, see [Outpost connectivity to AWS Regions](#) in the *AWS Outposts User Guide*.

For more information about accessing buckets and objects in S3 on Outposts, see [Working with S3 on Outposts buckets](#) and [Working with S3 on Outposts objects](#).

Cross-account elastic network interfaces

S3 on Outposts endpoints are named resources with Amazon Resource Names (ARNs). When these endpoints are created, AWS Outposts sets up multiple cross-account elastic network interfaces. S3 on Outposts cross-account elastic network interfaces are like other network interfaces with one exception: S3 on Outposts associates the cross-account elastic network interfaces to Amazon EC2 instances.

The S3 on Outposts Domain Name System (DNS) load balances your requests over the cross-account elastic network interface. S3 on Outposts creates the cross-account elastic network interface in your AWS account that is visible from the **Network interfaces** pane of the Amazon EC2 console.

For endpoints that use the ColP pool access type, S3 on Outposts allocates and associates IP addresses with the cross-account elastic network interface from the configured ColP pool.

Working with S3 on Outposts buckets

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You can use the same APIs and features on Outpost buckets as you do on Amazon S3, including access policies, encryption, and tagging. For more information, see [What is Amazon S3 on Outposts?](#)

You communicate with your Outpost buckets by using an access point and endpoint connection over a virtual private cloud (VPC). To access your S3 on Outposts buckets and objects, you must have an access point for the VPC and an endpoint for the same VPC. For more information, see [Networking for S3 on Outposts](#).

Buckets

In S3 on Outposts, bucket names are unique to an Outpost and require the AWS Region code for the Region the Outpost is homed to, AWS account ID, Outpost ID, and the bucket name to identify them.

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/bucket/bucket-name
```

For more information, see [Resource ARNs for S3 on Outposts](#).

Access points

Amazon S3 on Outposts supports virtual private cloud (VPC)-only access points as the only means to access your Outposts buckets.

Access points simplify managing data access at scale for shared datasets in Amazon S3. Access points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 object operations, such as `GetObject` and `PutObject`. With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Access points support only virtual-host-style addressing.

The following example shows the ARN format that you use for S3 on Outposts access points. The access point ARN includes the AWS Region code for the Region the Outpost is homed to, AWS account ID, Outpost ID, and access point name.

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/accesspoint/accesspoint-name
```

Endpoints

To route requests to an S3 on Outposts access point, you must create and configure an S3 on Outposts endpoint. With S3 on Outposts endpoints, you can privately connect your VPC to your Outpost bucket. S3 on Outposts endpoints are virtual uniform resource identifiers (URIs) of the entry point to your S3 on Outposts bucket. They are horizontally scaled, redundant, and highly available VPC components.

Each virtual private cloud (VPC) on your Outpost can have one associated endpoint, and you can have up to 100 endpoints per Outpost. You must create these endpoints to be able to access your Outpost buckets and perform object operations. Creating these endpoints also enables the API model and behaviors to be the same by allowing the same operations to work in S3 and S3 on Outposts.

API operations on S3 on Outposts

To manage Outpost bucket API operations, S3 on Outposts hosts a separate endpoint that is distinct from the Amazon S3 endpoint. This endpoint is `s3-outposts.region.amazonaws.com`.

To use Amazon S3 API operations, you must sign the bucket and objects using the correct ARN format. You must pass ARNs to API operations so that Amazon S3 can determine whether the

request is for Amazon S3 (`s3-control.region.amazonaws.com`) or for S3 on Outposts (`s3-outposts.region.amazonaws.com`). Based on the ARN format, S3 can then sign and route the request appropriately.

Whenever a request is sent to the Amazon S3 control plane, the SDK extracts the components from the ARN and includes the additional header `x-amz-outpost-id`, with the `outpost-id` value extracted from the ARN. The service name from the ARN is used to sign the request before it is routed to the S3 on Outposts endpoint. This behavior applies to all API operations handled by the `s3control` client.

The following table lists the extended API operations for Amazon S3 on Outposts and their changes relative to Amazon S3.

API	S3 on Outposts parameter value
CreateBucket	Bucket name as ARN, Outpost ID
ListRegionalBuckets	Outpost ID
DeleteBucket	Bucket name as ARN
DeleteBucketLifecycleConfiguration	Bucket name as ARN
GetBucketLifecycleConfiguration	Bucket name as ARN
PutBucketLifecycleConfiguration	Bucket name as ARN
GetBucketPolicy	Bucket name as ARN
PutBucketPolicy	Bucket name as ARN
DeleteBucketPolicy	Bucket name as ARN
GetBucketTagging	Bucket name as ARN
PutBucketTagging	Bucket name as ARN

API	S3 on Outposts parameter value
DeleteBucketTagging	Bucket name as ARN
CreateAccessPoint	Access point name as ARN
DeleteAccessPoint	Access point name as ARN
GetAccessPoint	Access point name as ARN
GetAccessPoint	Access point name as ARN
ListAccessPoints	Access point name as ARN
PutAccessPointPolicy	Access point name as ARN
GetAccessPointPolicy	Access point name as ARN
DeleteAccessPointPolicy	Access point name as ARN

Creating and managing S3 on Outposts buckets

For more information about creating and managing S3 on Outposts buckets, see the following topics.

Topics

- [Creating an S3 on Outposts bucket](#)
- [Adding tags for S3 on Outposts buckets](#)
- [Managing access to an Amazon S3 on Outposts bucket using a bucket policy](#)
- [Listing Amazon S3 on Outposts buckets](#)
- [Getting an S3 on Outposts bucket by using the AWS CLI and the SDK for Java](#)
- [Deleting your Amazon S3 on Outposts bucket](#)
- [Working with Amazon S3 on Outposts access points](#)
- [Working with Amazon S3 on Outposts endpoints](#)

Creating an S3 on Outposts bucket

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

Note

The AWS account that creates the bucket owns it and is the only one that can commit actions to it. Buckets have configuration properties, such as Outpost, tag, default encryption, and access point settings. The access point settings include the virtual private cloud (VPC), the access point policy for accessing the objects in the bucket, and other metadata. For more information, see [S3 on Outposts specifications](#).

If you want to create a bucket that uses AWS PrivateLink to provide bucket and endpoint management access through *interface VPC endpoints* in your virtual private cloud (VPC), see [AWS PrivateLink for S3 on Outposts](#).

The following examples show you how to create an S3 on Outposts bucket by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose **Create Outposts bucket**.
4. For **Bucket name**, enter a Domain Name System (DNS)-compliant name for your bucket.

The bucket name must:

- Be unique within the AWS account, the Outpost, and the AWS Region that the Outpost is homed to.
- Be 3–63 characters long.
- Not contain uppercase characters.
- Start with a lowercase letter or number.

After you create the bucket, you can't change its name. For information about naming buckets, see [Bucket naming rules](#).

⚠️ Important

Avoid including sensitive information such as account numbers in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

5. For **Outpost**, choose the Outpost where you want the bucket to reside.
6. Under **Bucket Versioning**, set the S3 Versioning state for your S3 on Outposts bucket to one of the following options:
 - **Disable** (default) – The bucket remains unversioned.
 - **Enable** – Enables S3 Versioning for the objects in the bucket. All objects added to the bucket receive a unique version ID.

For more information about S3 Versioning, see [Managing S3 Versioning for your S3 on Outposts bucket](#).

7. (Optional) Add any **optional tags** that you would like to associate with the Outposts bucket. You can use tags to track criteria for individual projects or groups of projects, or to label your buckets by using cost-allocation tags.

By default, all objects stored in your Outposts bucket are stored by using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). You can also explicitly choose to store objects by using server-side encryption with customer-provided encryption keys (SSE-C). To change the encryption type, you must use the REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

8. In the **Outposts access point settings** section, enter the access point name.

S3 on Outposts access points simplify managing data access at scale for shared datasets in S3 on Outposts. Access points are named network endpoints that are attached to Outposts buckets that you can use to perform S3 object operations. For more information, see [Access points](#).

Access point names must be unique within the account for this Region and Outpost, and comply with the [Access points restrictions and limitations](#).

9. Choose the **VPC** for this Amazon S3 on Outposts access point.

If you don't have a VPC, choose **Create VPC**. For more information, see [Creating access points restricted to a virtual private cloud](#).

A virtual private cloud (VPC) enables you to launch AWS resources into a virtual network that you define. This virtual network closely resembles a traditional network that you would operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

10. (Optional for an existing VPC) Choose an **Endpoint subnet** for your endpoint.

A subnet is a range of IP addresses in your VPC. If you don't have the subnet that you want, choose **Create subnet**. For more information, see [Networking for S3 on Outposts](#).

11. (Optional for an existing VPC) Choose an **Endpoint security group** for your endpoint.

A [security group](#) acts as a virtual firewall to control inbound and outbound traffic.

12. (Optional for an existing VPC) Choose the **Endpoint access type**:

- **Private** – To be used with the VPC.
- **Customer owned IP** – To be used with a customer-owned IP address pool (CoIP pool) from within your on-premises network.

13. (Optional) Specify the **Outpost access point policy**. The console automatically displays the **Amazon Resource Name (ARN)** for the access point, which you can use in the policy.

14. Choose **Create Outposts bucket**.

 **Note**

It can take up to 5 minutes for your Outpost endpoint to be created and your bucket to be ready to use. To configure additional bucket settings, choose **View details**.

Using the AWS CLI

Example

The following example creates an S3 on Outposts bucket (`s3-outposts:CreateBucket`) by using the AWS CLI. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control create-bucket --bucket example-outposts-bucket --outpost-id op-01ac5d28a6a232904
```

Using the AWS SDK for Java

Example

The following example creates an S3 on Outposts bucket (`s3-outposts:CreateBucket`) by using the SDK for Java.

```
import com.amazonaws.services.s3control.model.*;  
  
public String createBucket(String bucketName) {  
  
    CreateBucketRequest reqCreateBucket = new CreateBucketRequest()  
        .withBucket(bucketName)  
        .withOutpostId(OutpostId)  
        .withCreateBucketConfiguration(new CreateBucketConfiguration());  
  
    CreateBucketResult respCreateBucket =  
s3ControlClient.createBucket(reqCreateBucket);  
    System.out.printf("CreateBucket Response: %s%n", respCreateBucket.toString());  
  
    return respCreateBucket.getBucketArn();  
}
```

Adding tags for S3 on Outposts buckets

You can add tags for your Amazon S3 on Outposts buckets to track storage costs and other criteria for individual projects or groups of projects.

Note

The AWS account that creates the bucket owns it and is the only one that can change its tags.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket whose tags you want to edit.
4. Choose the **Properties** tab.
5. Under **Tags**, choose **Edit**.
6. Choose **Add new tag**, and enter the **Key** and optional **Value**.

Add any tags that you would like to associate with an Outposts bucket to track other criteria for individual projects or groups of projects.

7. Choose **Save changes**.

Using the AWS CLI

The following AWS CLI example applies a tagging configuration to an S3 on Outposts bucket by using a JSON document in the current folder that specifies tags (*tagging.json*). To use this example, replace each *user input placeholder* with your own information.

```
aws s3control put-bucket-tagging --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket --tagging file://tagging.json
```

tagging.json

```
{  
  "TagSet": [  
    {  
      "Key": "organization",  
      "Value": "marketing"  
    }]
```

```
    ]  
}
```

The following AWS CLI example applies a tagging configuration to an S3 on Outposts bucket directly from the command line.

```
aws s3control put-bucket-tagging --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket --tagging 'TagSet=[{Key=organization,Value=marketing}]'
```

For more information about this command, see [put-bucket-tagging](#) in the *AWS CLI Reference*.

Managing access to an Amazon S3 on Outposts bucket using a bucket policy

A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. Bucket policies are limited to 20 KB in size. For more information, see [Bucket policy](#).

You can update your bucket policy to manage access to your Amazon S3 on Outposts bucket. For more information, see the following topics.

Topics

- [Adding or editing a bucket policy for an Amazon S3 on Outposts bucket](#)
- [Viewing the bucket policy for your Amazon S3 on Outposts bucket](#)
- [Deleting the bucket policy for your Amazon S3 on Outposts bucket](#)
- [Bucket policy examples](#)

Adding or editing a bucket policy for an Amazon S3 on Outposts bucket

A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. Bucket policies are limited to 20 KB in size. For more information, see [Bucket policy](#).

The following topics show you how to update your Amazon S3 on Outposts bucket policy by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or AWS SDK for Java.

Using the S3 console

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket whose bucket policy you want to edit.
4. Choose the **Permissions** tab.
5. In the **Outposts bucket policy** section, to create or edit new policy, choose **Edit**.

You can now add or edit the S3 on Outposts bucket policy. For more information, see [Setting up IAM with S3 on Outposts](#).

Using the AWS CLI

The following AWS CLI example puts a policy on an Outposts bucket.

1. Save the following bucket policy to a JSON file. In this example, the file is named `policy1.json`. Replace the `user input placeholders` with your own information.

```
{  
    "Version": "2012-10-17",  
    "Id": "testBucketPolicy",  
    "Statement": [  
        {  
            "Sid": "st1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "123456789012"  
            },  
            "Action": "s3-outposts:*",  
            "Resource": "arn:aws:s3-  
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-  
bucket"  
        }  
    ]  
}
```

```
}
```

2. Submit the JSON file as part of the put-bucket-policy CLI command. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control put-bucket-policy --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket --policy file://policy1.json
```

Using the AWS SDK for Java

The following SDK for Java example puts a policy on an Outposts bucket.

```
import com.amazonaws.services.s3control.model.*;  
  
public void putBucketPolicy(String bucketArn) {  
  
    String policy = "{\"Version\":\"2012-10-17\", \"Id\":\"testBucketPolicy\",  
    \"Statement\":[{\"Sid\":\"st1\", \"Effect\":\"Allow\", \"Principal\":{\"AWS\":\"\" +  
    AccountId+ "\"}, \"Action\":\"s3-outposts:*\", \"Resource\":\"\" + bucketArn + "\"}]}";  
  
    PutBucketPolicyRequest reqPutBucketPolicy = new PutBucketPolicyRequest()  
        .withAccountId(AccountId)  
        .withBucket(bucketArn)  
        .withPolicy(policy);  
  
    PutBucketPolicyResult respPutBucketPolicy =  
    s3ControlClient.putBucketPolicy(reqPutBucketPolicy);  
    System.out.printf("PutBucketPolicy Response: %s%n",  
    respPutBucketPolicy.toString());  
  
}
```

Viewing the bucket policy for your Amazon S3 on Outposts bucket

A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. Bucket policies are limited to 20 KB in size. For more information, see [Bucket policy](#).

The following topics show you how to view your Amazon S3 on Outposts bucket policy by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or AWS SDK for Java.

Using the S3 console

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket whose permission you want to edit.
4. Choose the **Permissions** tab.
5. In the **Outposts bucket policy** section, you can review your existing bucket policy. For more information, see [Setting up IAM with S3 on Outposts](#).

Using the AWS CLI

The following AWS CLI example gets a policy for an Outposts bucket. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control get-bucket-policy --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket
```

Using the AWS SDK for Java

The following SDK for Java example gets a policy for an Outposts bucket.

```
import com.amazonaws.services.s3control.model.*;  
  
public void getBucketPolicy(String bucketArn) {  
  
    GetBucketPolicyRequest reqGetBucketPolicy = new GetBucketPolicyRequest()  
        .withAccountId(AccountId)  
        .withBucket(bucketArn);  
  
    GetBucketPolicyResult respGetBucketPolicy =  
        s3ControlClient.getBucketPolicy(reqGetBucketPolicy);  
    System.out.printf("GetBucketPolicy Response: %s%n",  
        respGetBucketPolicy.toString());  
}
```

}

Deleting the bucket policy for your Amazon S3 on Outposts bucket

A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. Bucket policies are limited to 20 KB in size. For more information, see [Bucket policy](#).

The following topics show you how to view your Amazon S3 on Outposts bucket policy by using the AWS Management Console or AWS Command Line Interface (AWS CLI).

Using the S3 console

To delete a bucket policy

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket whose permission you want to edit.
4. Choose the **Permissions** tab.
5. In the **Outposts bucket policy** section, choose **Delete**.
6. Confirm the deletion.

Using the AWS CLI

The following example deletes the bucket policy for an S3 on Outposts bucket (s3-outposts:DeleteBucket) by using the AWS CLI. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control delete-bucket-policy --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket
```

Bucket policy examples

With S3 on Outposts bucket policies, you can secure access to objects in your S3 on Outposts buckets, so that only users with the appropriate permissions can access them. You can even prevent

authenticated users without the appropriate permissions from accessing your S3 on Outposts resources.

This section presents examples of typical use cases for S3 on Outposts bucket policies. To test these policies, replace the *user input placeholders* with your own information (such as your bucket name).

To grant or deny permissions to a set of objects, you can use wildcard characters (*) in Amazon Resource Names (ARNs) and other values. For example, you can control access to groups of objects that begin with a common [prefix](#) or end with a given extension, such as .html.

For more information about AWS Identity and Access Management (IAM) policy language, see [Setting up IAM with S3 on Outposts](#).

 **Note**

When testing [s3outposts](#) permissions by using the Amazon S3 console, you must grant additional permissions that the console requires, such as s3outposts:createendpoint, s3outposts:listendpoints, and so on.

Additional resources for creating bucket policies

- For a list of the IAM policy actions, resources, and condition keys you can use when creating an S3 on Outposts bucket policy, see [Actions, resources, and condition keys for Amazon S3 on Outposts](#).
- For guidance on creating your S3 on Outposts policy, see [Adding or editing a bucket policy for an Amazon S3 on Outposts bucket](#).

Topics

- [Managing access to an Amazon S3 on Outposts bucket based on specific IP addresses](#)

Managing access to an Amazon S3 on Outposts bucket based on specific IP addresses

A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy that you can use to grant access permissions to your bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects

in the bucket that are owned by the bucket owner. Bucket policies are limited to 20 KB in size. For more information, see [Bucket policy](#).

Restrict access to specific IP addresses

The following example denies all users from performing any [S3 on Outposts operations](#) on objects in the specified buckets unless the request originates from the specified range of IP addresses.

Note

When restricting access to a specific IP address, make sure that you also specify which VPC endpoints, VPC source IP addresses, or external IP addresses can access the S3 on Outposts bucket. Otherwise, you might lose access to the bucket if your policy denies all users from performing any [s3outposts](#) operations on objects in your S3 on Outposts bucket without the proper permissions already in place.

This policy's Condition statement identifies [**192.0.2.0/24**](#) as the range of allowed IP version 4 (IPv4) IP addresses.

The Condition block uses the NotIpAddress condition and the aws:SourceIp condition key, which is an AWS wide condition key. The aws:SourceIp condition key can only be used for public IP address ranges. For more information about these condition keys, see [Actions, resources, and condition keys for S3 on Outposts](#). The aws:SourceIp IPv4 values use standard CIDR notation. For more information, see [IAM JSON policy elements reference](#) in the [IAM User Guide](#).

Warning

Before using this S3 on Outposts policy, replace the [**192.0.2.0/24**](#) IP address range in this example with an appropriate value for your use case. Otherwise, you'll lose the ability to access your bucket.

```
{  
    "Version": "2012-10-17",  
    "Id": "S3OutpostsPolicyId1",  
    "Statement": [  
        {  
            "Sid": "IPAllow",  
            "Effect": "Deny",  
            "Condition": {  
                "NotIpAddress": {  
                    "aws:SourceIp": "192.0.2.0/24"  
                }  
            }  
        }  
    ]  
}
```

```
        "Principal": "*",
        "Action": "s3outposts:*",
        "Resource": [
            "arn:aws:s3-outposts:region:111122223333:outpost/OUTPOSTS-ID/accesspoint/EXAMPLE-ACCESS-POINT-NAME"
                "arn:aws:aws:s3-outposts:region:111122223333:outpost/OUTPOSTS-ID/bucket/DOC-EXAMPLE-BUCKET"
            ],
            "Condition": {
                "NotIpAddress": {
                    "aws:SourceIp": "192.0.2.0/24"
                }
            }
        ]
    }
```

Allow both IPv4 and IPv6 addresses

When you start using IPv6 addresses, we recommend that you update all of your organization's policies with your IPv6 address ranges in addition to your existing IPv4 ranges. Doing this will help to make sure that the policies continue to work as you make the transition to IPv6.

The following S3 on Outposts example bucket policy shows how to mix IPv4 and IPv6 address ranges to cover all of your organization's valid IP addresses. The example policy allows access to the example IP addresses *192.0.2.1* and *2001:DB8:1234:5678::1* and denies access to the addresses *203.0.113.1* and *2001:DB8:1234:5678:ABCD::1*.

The `aws:SourceIp` condition key can only be used for public IP address ranges. The IPv6 values for `aws:SourceIp` must be in standard CIDR format. For IPv6, we support using `::` to represent a range of 0s (for example, `2001:DB8:1234:5678::/64`). For more information, see [IP address condition operators](#) in the *IAM User Guide*.

Warning

Replace the IP address ranges in this example with appropriate values for your use case before using this S3 on Outposts policy. Otherwise, you might lose the ability to access your bucket.

            }
        }
    }
]
```

Listing Amazon S3 on Outposts buckets

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through

the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

For more information about working with buckets in S3 on Outposts, see [Working with S3 on Outposts buckets](#).

The following examples show you how to return a list of your S3 on Outposts buckets by using the AWS Management Console, AWS CLI, and AWS SDK for Java.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Under **Outposts buckets**, review your list of S3 on Outposts buckets.

Using the AWS CLI

The following AWS CLI example gets a list of buckets in an Outpost. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [list-regional-buckets](#) in the *AWS CLI Reference*.

```
aws s3control list-regional-buckets --account-id 123456789012 --outpost-id op-01ac5d28a6a232904
```

Using the AWS SDK for Java

The following SDK for Java example gets a list of buckets in an Outpost. For more information, see [ListRegionalBuckets](#) in the *Amazon Simple Storage Service API Reference*.

```
import com.amazonaws.services.s3control.model.*;  
  
public void listRegionalBuckets() {  
  
    ListRegionalBucketsRequest reqListBuckets = new ListRegionalBucketsRequest()  
        .withAccountId(AccountId)  
        .withOutpostId(OutpostId);  
  
    ListRegionalBucketsResult respListBuckets =  
        s3ControlClient.listRegionalBuckets(reqListBuckets);  
}
```

```
System.out.printf("ListRegionalBuckets Response: %s%n",
respListBuckets.toString());
}
```

Getting an S3 on Outposts bucket by using the AWS CLI and the SDK for Java

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

The following examples show you how to get an S3 on Outposts bucket by using the AWS CLI and AWS SDK for Java.

Note

When you're working with Amazon S3 on Outposts through the AWS CLI or AWS SDKs, you provide the access point ARN for the Outpost in place of the bucket name. The access point ARN takes the following form, where *region* is the AWS Region code for the Region that the Outpost is homed to:

`arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-access-point`

For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

Using the AWS CLI

The following S3 on Outposts example gets a bucket by using the AWS CLI. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [get-bucket](#) in the *AWS CLI Reference*.

```
aws s3control get-bucket --account-id 123456789012 --bucket "arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket"
```

Using the AWS SDK for Java

The following S3 on Outposts example gets a bucket by using the SDK for Java. For more information, see [GetBucket](#) in the *Amazon Simple Storage Service API Reference*.

```
import com.amazonaws.services.s3control.model.*;  
  
public void getBucket(String bucketArn) {  
  
    GetBucketRequest reqGetBucket = new GetBucketRequest()  
        .withBucket(bucketArn)  
        .withAccountId(AccountId);  
  
    GetBucketResult respGetBucket = s3ControlClient.getBucket(reqGetBucket);  
    System.out.printf("GetBucket Response: %s%n", respGetBucket.toString());  
  
}
```

Deleting your Amazon S3 on Outposts bucket

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

For more information about working with buckets in S3 on Outposts, see [Working with S3 on Outposts buckets](#).

The AWS account that creates the bucket owns it and is the only one that can delete it.

Note

- Outposts buckets must be empty before they can be deleted.

The Amazon S3 console doesn't support S3 on Outposts object actions. To delete objects in an S3 on Outposts bucket, you must use the REST API, AWS CLI, or AWS SDKs.

- Before you can delete an Outposts bucket, you must delete any Outposts access points for the bucket. For more information, see [Deleting an access point](#).
- You cannot recover a bucket after it has been deleted.

The following examples show you how to delete an S3 on Outposts bucket by using the AWS Management Console and AWS Command Line Interface (AWS CLI).

Using the S3 console

- Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- In the left navigation pane, choose **Outposts buckets**.
- Choose the bucket that you want to delete, and choose **Delete**.
- Confirm the deletion.

Using the AWS CLI

The following example deletes an S3 on Outposts bucket (`s3-outposts:DeleteBucket`) by using the AWS CLI. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control delete-bucket --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket
```

Working with Amazon S3 on Outposts access points

To access your Amazon S3 on Outposts bucket, you must create and configure an access point.

Access points simplify managing data access at scale for shared datasets in Amazon S3. Access points are named network endpoints that are attached to buckets that you can use to perform

Amazon S3 object operations, such as `GetObject` and `PutObject`. With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Access points support only virtual-host-style addressing.

 **Note**

The AWS account that creates the Outposts bucket owns it and is the only one that can assign access points to it.

The following sections describe how to create and manage access points for S3 on Outposts buckets.

Topics

- [Creating an S3 on Outposts access point](#)
- [Using a bucket-style alias for your S3 on Outposts bucket access point](#)
- [Viewing information about an access point configuration](#)
- [View a list of your Amazon S3 on Outposts access points](#)
- [Deleting an access point](#)
- [Adding or editing an access point policy](#)
- [Viewing an access point policy for an S3 on Outposts access point](#)

Creating an S3 on Outposts access point

To access your Amazon S3 on Outposts bucket, you must create and configure an access point.

Access points simplify managing data access at scale for shared datasets in Amazon S3. Access points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 object operations, such as `GetObject` and `PutObject`. With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Access points support only virtual-host-style addressing.

The following examples show you how to create an S3 on Outposts access point by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Note

The AWS account that creates the Outposts bucket owns it and is the only one that can assign access points to it.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket that you want to create an Outposts access point for.
4. Choose the **Outposts access points** tab.
5. In the **Outposts access points** section, choose **Create Outposts access point**.
6. In **Outposts access point settings**, enter a name for the access point, and then choose the virtual private cloud (VPC) for the access point.
7. If you want to add a policy for your access point, enter it in the **Outposts access point policy** section.

For more information, see [Setting up IAM with S3 on Outposts](#).

Using the AWS CLI

Example

The following AWS CLI example creates an access point for an Outposts bucket. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control create-access-point --account-id 123456789012
--name example-outposts-access-point --bucket "arn:aws:s3-
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-
bucket" --vpc-configuration VpcId=example-vpc-12345
```

Using the AWS SDK for Java

Example

The following SDK for Java example creates an access point for an Outposts bucket. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.services.s3control.model.*;  
  
public String createAccessPoint(String bucketArn, String accessPointName) {  
  
    CreateAccessPointRequest reqCreateAP = new CreateAccessPointRequest()  
        .withAccountId(AccountId)  
        .withBucket(bucketArn)  
        .withName(accessPointName)  
        .withVpcConfiguration(new VpcConfiguration().withVpcId("vpc-12345"));  
  
    CreateAccessPointResult respCreateAP =  
s3ControlClient.createAccessPoint(reqCreateAP);  
    System.out.printf("CreateAccessPoint Response: %s%n", respCreateAP.toString());  
  
    return respCreateAP.getAccessPointArn();  
}
```

Using a bucket-style alias for your S3 on Outposts bucket access point

With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Every time you create an access point for a bucket, S3 on Outposts automatically generates an access point alias. You can use this access point alias instead of an access point ARN for any data plane operation. For example, you can use an access point alias to perform object-level operations such as PUT, GET, LIST, and more. For a list of these operations, see [Amazon S3 API operations for managing objects](#).

The following examples show an ARN and access point alias for an access point named *my-access-point*.

- **Access point ARN** – arn:aws:s3-outposts:*region:123456789012:outpost/op-01ac5d28a6a232904*/accesspoint/*my-access-point*
- **Access point alias** – *my-access-po-001ac5d28a6a232904e8xz5w8ijx1qz1bp3i3kuse10--op-s3*

For more information about ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *AWS General Reference*.

For more information about access point aliases, see the following topics.

Topics

- [Access point aliases](#)
- [Using an access point alias in an S3 on Outposts object operation](#)
- [Limitations](#)

Access point aliases

An access point alias is created within the same namespace as an S3 on Outposts bucket. When you create an access point, S3 on Outposts automatically generates an access point alias that cannot be changed. An access point alias meets all the requirements of a valid S3 on Outposts bucket name and consists of the following parts:

access point name prefix-metadata--op-s3

 **Note**

The --op-s3 suffix is reserved for access point aliases, we recommend that you don't use it for bucket or access point names. For more information about S3 on Outposts bucket-naming rules, see [Working with S3 on Outposts buckets](#).

Finding the access point alias

The following examples show you how to find an access point alias by using the Amazon S3 console and the AWS CLI.

Example : Find and copy an access point alias in the Amazon S3 console

After you create an access point in the console, you can get the access point alias from the **Access Point alias** column in the **Access Points** list.

To copy an access point alias

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts access points**.
3. To copy the access point alias, do one of the following:
 - In the **Access Points** list, select the option button next to the access point name, and then choose **Copy Access Point alias**.

- Choose the access point name. Then, under **Outposts access point overview**, copy the access point alias.

Example : Create an access point by using the AWS CLI and find the access point alias in the response

The following AWS CLI example for the `create-access-point` command creates the access point and returns the automatically generated access point alias. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control create-access-point --bucket example-outposts-bucket --name example-outposts-access-point --account-id 123456789012

{
    "AccessPointArn": "arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-access-point",
    "Alias": "example-outp-001ac5d28a6a232904e8xz5w8ijx1qzlbp3i3kuse10--op-s3"
}
```

Example : Get an access point alias by using the AWS CLI

The following AWS CLI example for the `get-access-point` command returns information about the specified access point. This information includes the access point alias. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control get-access-point --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket --name example-outposts-access-point --account-id 123456789012

{
    "Name": "example-outposts-access-point",
    "Bucket": "example-outposts-bucket",
    "NetworkOrigin": "Vpc",
    "VpcConfiguration": {
        "VpcId": "vpc-01234567890abcdef"
    },
    "PublicAccessBlockConfiguration": {
        "BlockPublicAcls": true,
        "IgnorePublicAcls": true,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    }
}
```

```
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2022-09-18T17:49:15.584000+00:00",
    "Alias": "example-outp-o0b1d075431d83bebde8xz5w8ijx1qz1bp3i3kuse10--op-s3"
}
```

Example : List access points to find an access point alias by using the AWS CLI

The following AWS CLI example for the list-access-points command lists information about the specified access point. This information includes the access point alias. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control list-access-points --account-id 123456789012 --bucket arn:aws:s3-
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-
bucket

{
    "AccessPointList": [
        {
            "Name": "example-outposts-access-point",
            "NetworkOrigin": "Vpc",
            "VpcConfiguration": {
                "VpcId": "vpc-01234567890abcdef"
            },
            "Bucket": "example-outposts-bucket",
            "AccessPointArn": "arn:aws:s3-
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-
access-point",
            "Alias": "example-outp-o0b1d075431d83bebde8xz5w8ijx1qz1bp3i3kuse10--op-s3"
        }
    ]
}
```

Using an access point alias in an S3 on Outposts object operation

When adopting access points, you can use access point alias without requiring extensive code changes.

This AWS CLI example shows a get-object operation for an S3 on Outposts bucket. This example uses the access point alias as the value for --bucket instead of the full access point ARN.

```
aws s3api get-object --bucket my-access-po-
o0b1d075431d83bebde8xz5w8ijx1qz1bp3i3kuse10--op-s3 --key testkey sample-object.rtf
```

```
{  
    "AcceptRanges": "bytes",  
    "LastModified": "2020-01-08T22:16:28+00:00",  
    "ContentLength": 910,  
    "ETag": "\"00751974dc146b76404bb7290f8f51bb\"",  
    "VersionId": "null",  
    "ContentType": "text/rtf",  
    "Metadata": {}  
}
```

Limitations

- Aliases cannot be configured by customers.
- Aliases cannot be deleted or modified or disabled on an access point.
- You can't use an access point alias for S3 on Outposts control plane operations. For a list of S3 on Outposts control plane operations, see [Amazon S3 Control API operations for managing buckets](#).
- Aliases cannot be used in AWS Identity and Access Management (IAM) policies.

Viewing information about an access point configuration

Access points simplify managing data access at scale for shared datasets in Amazon S3. Access points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 object operations, such as `GetObject` and `PutObject`. With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Access points support only virtual-host-style addressing.

The following topics show you how to return configuration information for an S3 on Outposts access point by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts access points**.
3. Choose the Outposts access point that you want to view configuration details for.
4. Under **Outposts access point overview**, review the access point configuration details.

Using the AWS CLI

The following AWS CLI example gets an access point for an Outposts bucket. Replace the *user input placeholders* with your own information.

```
aws s3control get-access-point --account-id 123456789012 --name arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-access-point
```

Using the AWS SDK for Java

The following SDK for Java example gets an access point for an Outposts bucket.

```
import com.amazonaws.services.s3control.model.*;  
  
public void getAccessPoint(String accessPointArn) {  
  
    GetAccessPointRequest reqGetAP = new GetAccessPointRequest()  
        .withAccountId(AccountId)  
        .withName(accessPointArn);  
  
    GetAccessPointResult respGetAP = s3ControlClient.getAccessPoint(reqGetAP);  
    System.out.printf("GetAccessPoint Response: %s%n", respGetAP.toString());  
  
}
```

View a list of your Amazon S3 on Outposts access points

Access points simplify managing data access at scale for shared datasets in Amazon S3. Access points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 object operations, such as `GetObject` and `PutObject`. With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Access points support only virtual-host-style addressing.

The following topics show you how to return a list of your S3 on Outposts access points by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Outposts access points**.
3. Under **Outposts access points**, review your list of S3 on Outposts access points.

Using the AWS CLI

The following AWS CLI example lists the access points for an Outposts bucket. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control list-access-points --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket
```

Using the AWS SDK for Java

The following SDK for Java example lists the access points for an Outposts bucket.

```
import com.amazonaws.services.s3control.model.*;  
  
public void listAccessPoints(String bucketArn) {  
  
    ListAccessPointsRequest reqListAPs = new ListAccessPointsRequest()  
        .withAccountId(AccountId)  
        .withBucket(bucketArn);  
  
    ListAccessPointsResult respListAPs = s3ControlClient.listAccessPoints(reqListAPs);  
    System.out.printf("ListAccessPoints Response: %s%n", respListAPs.toString());  
}
```

Deleting an access point

Access points simplify managing data access at scale for shared datasets in Amazon S3. Access points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 object operations, such as `GetObject` and `PutObject`. With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Access points support only virtual-host-style addressing.

The following examples show you how to delete an access point by using the AWS Management Console and the AWS Command Line Interface (AWS CLI).

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts access points**.
3. In the **Outposts access points** section, choose the Outposts access point that you want to delete.
4. Choose **Delete**.
5. Confirm the deletion.

Using the AWS CLI

The following AWS CLI example deletes an Outposts access point. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control delete-access-point --account-id 123456789012 --name arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-access-point
```

Adding or editing an access point policy

Access points have distinct permissions and network controls that Amazon S3 on Outposts applies for any request that is made through that access point. Each access point enforces a customized access point policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For more information, see [Access points](#).

The following topics show you how to add or edit the access point policy for your S3 on Outposts access point by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket that you want to edit the access point policy for.
4. Choose the **Outposts access points** tab.
5. In the **Outposts access points** section, choose the access point whose policy you want to edit, and choose **Edit policy**.

6. Add or edit the policy in the **Outposts access point policy** section. For more information, see [Setting up IAM with S3 on Outposts](#).

Using the AWS CLI

The following AWS CLI example puts a policy on an Outposts access point.

1. Save the following access point policy to a JSON file. In this example, the file is named `appolicy1.json`. Replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Id": "exampleAccessPointPolicy",  
    "Statement": [  
        {  
            "Sid": "st1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "123456789012"  
            },  
            "Action": "s3-outposts:*",  
            "Resource": "arn:aws:s3-  
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-  
outposts-access-point  
        }  
    ]  
}
```

2. Submit the JSON file as part of the `put-access-point-policy` CLI command. Replace the *user input placeholders* with your own information.

```
aws s3control put-access-point-policy --account-id 123456789012 --name arn:aws:s3-  
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-  
outposts-access-point --policy file://appolicy1.json
```

Using the AWS SDK for Java

The following SDK for Java example puts a policy on an Outposts access point.

```
import com.amazonaws.services.s3control.model.*;
```

```
public void putAccessPointPolicy(String accessPointArn) {  
  
    String policy = "{\"Version\":\"2012-10-17\", \"Id\":\"testAccessPointPolicy\",  
    \"Statement\":[{\"Sid\":\"st1\", \"Effect\":\"Allow\", \"Principal\":{\"AWS\":\"\" +  
    AccountId + "\"}, \"Action\":\"s3-outposts:*\", \"Resource\":\"\" + accessPointArn +  
    "\"}]}\";  
  
    PutAccessPointPolicyRequest reqPutAccessPointPolicy = new  
    PutAccessPointPolicyRequest()  
        .withAccountId(AccountId)  
        .withName(accessPointArn)  
        .withPolicy(policy);  
  
    PutAccessPointPolicyResult respPutAccessPointPolicy =  
    s3ControlClient.putAccessPointPolicy(reqPutAccessPointPolicy);  
    System.out.printf("PutAccessPointPolicy Response: %s%n",  
    respPutAccessPointPolicy.toString());  
    printWriter.printf("PutAccessPointPolicy Response: %s%n",  
    respPutAccessPointPolicy.toString());  
  
}
```

Viewing an access point policy for an S3 on Outposts access point

Access points have distinct permissions and network controls that Amazon S3 on Outposts applies for any request that is made through that access point. Each access point enforces a customized access point policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For more information, see [Access points](#).

For more information about working with access points in S3 on Outposts, see [Working with S3 on Outposts buckets](#).

The following topics show you how to view your S3 on Outposts access point policy by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts access points**.
3. Choose the Outposts access point that you want to view the policy for.
4. On the **Permissions** tab, review the S3 on Outposts access point policy.

5. To edit the access point policy, see [Adding or editing an access point policy](#).

Using the AWS CLI

The following AWS CLI example gets a policy for an Outposts access point. To run this command, replace the *user input placeholders* with your own information.

```
aws s3control get-access-point-policy --account-id 123456789012 --name arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-access-point
```

Using the AWS SDK for Java

The following SDK for Java example gets a policy for an Outposts access point.

```
import com.amazonaws.services.s3control.model.*;  
  
public void getAccessPointPolicy(String accessPointArn) {  
  
    GetAccessPointPolicyRequest reqGetAccessPointPolicy = new  
    GetAccessPointPolicyRequest()  
        .withAccountId(AccountId)  
        .withName(accessPointArn);  
  
    GetAccessPointPolicyResult respGetAccessPointPolicy =  
    s3ControlClient.getAccessPointPolicy(reqGetAccessPointPolicy);  
    System.out.printf("GetAccessPointPolicy Response: %s%n",  
    respGetAccessPointPolicy.toString());  
    printWriter.printf("GetAccessPointPolicy Response: %s%n",  
    respGetAccessPointPolicy.toString());  
  
}
```

Working with Amazon S3 on Outposts endpoints

To route requests to an Amazon S3 on Outposts access point, you must create and configure an S3 on Outposts endpoint. In order to create an endpoint, you will need an active connection with your service link to your Outposts home region. Each virtual private cloud (VPC) on your Outpost can have one associated endpoint. For more information about endpoint quotas, see [S3 on Outposts network requirements](#). You must create an endpoint to be able to access your Outposts buckets and perform object operations. For more information, see [Endpoints](#).

After you create an endpoint, you can use the 'Status' field, to understand the state of the endpoint. If your Outposts is offline, it will return a CREATE_FAILED. You can check your service link connection, delete the endpoint, and retry the create operation after your connection has resumed. For a list of additional error codes, see below. For more information, see [Endpoints](#).

API	Status	Failed Reason Error Code	Message - Failed Reason
CreateEndpoint	Create_Failed	OutpostNotReachable	Endpoint could not be created as the service link connection to your Outposts home Region is down. Check your connection, delete the endpoint, and try again.
CreateEndpoint	Create_Failed	InternalError	Endpoint could not be created due to Internal Error. Please delete the endpoint and create again.
DeleteEndpoint	Delete_Failed	OutpostNotReachable	Endpoint could not be deleted as the service link connection to your Outposts home Region is down. Check your connection and please try again.
DeleteEndpoint	Delete_Failed	InternalError	Endpoint could not be deleted due to Internal Error. Please try again.

For more information about working with buckets on S3 on Outposts, see [Working with S3 on Outposts buckets](#).

The following sections describe how to create and manage endpoints for S3 on Outposts.

Topics

- [Creating an endpoint on an Outpost](#)
- [Viewing a list of your Amazon S3 on Outposts endpoints](#)
- [Deleting an Amazon S3 on Outposts endpoint](#)

Creating an endpoint on an Outpost

To route requests to an Amazon S3 on Outposts access point, you must create and configure an S3 on Outposts endpoint. In order to create an endpoint, you will need an active connection with your service link to your Outposts home region. Each virtual private cloud (VPC) on your Outpost can have one associated endpoint. For more information about endpoint quotas, see [S3 on Outposts network requirements](#). You must create an endpoint to be able to access your Outposts buckets and perform object operations. For more information, see [Endpoints](#).

Permissions

For more information about the permissions that are required to create an endpoint, see [Permissions for S3 on Outposts endpoints](#).

When you create an endpoint, S3 on Outposts also creates a service-linked role in your AWS account. For more information, see [Using service-linked roles for Amazon S3 on Outposts](#).

The following examples show you how to create an S3 on Outposts endpoint by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts access points**.
3. Choose the **Outposts endpoints** tab.
4. Choose **Create Outposts endpoint**.
5. Under **Outpost**, choose the Outpost to create this endpoint on.
6. Under **VPC**, choose a VPC that does not yet have an endpoint and that also complies with the rules for Outposts endpoints.

A virtual private cloud (VPC) enables you to launch AWS resources into a virtual network that you define. This virtual network closely resembles a traditional network that you would operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

If you don't have a VPC, choose **Create VPC**. For more information, see [Creating access points restricted to a virtual private cloud](#).

7. Choose **Create Outposts endpoint**.

Using the AWS CLI

Example

The following AWS CLI example creates an endpoint for an Outpost by using the VPC resource access type. The VPC is derived from the subnet. To run this command, replace the *user input placeholders* with your own information.

```
aws s3outposts create-endpoint --outpost-id op-01ac5d28a6a232904 --subnet-id  
subnet-8c7a57c5 --security-group-id sg-ab19e0d1
```

The following AWS CLI example creates an endpoint for an Outpost by using the customer-owned IP address pool (CoIP pool) access type. To run this command, replace the *user input placeholders* with your own information.

```
aws s3outposts create-endpoint --outpost-id op-01ac5d28a6a232904 --subnet-id  
subnet-8c7a57c5 --security-group-id sg-ab19e0d1 --access-type CustomerOwnedIp --  
customer-owned-ipv4-pool ipv4pool-coip-12345678901234567
```

Using the AWS SDK for Java

Example

The following SDK for Java example creates an endpoint for an Outpost. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.services.s3outposts.AmazonS3Outposts;  
import com.amazonaws.services.s3outposts.AmazonS3OutpostsClientBuilder;  
import com.amazonaws.services.s3outposts.model.CreateEndpointRequest;  
import com.amazonaws.services.s3outposts.model.CreateEndpointResult;  
  
public void createEndpoint() {  
    AmazonS3Outposts s3OutpostsClient = AmazonS3OutpostsClientBuilder  
        .standard().build();  
  
    CreateEndpointRequest createEndpointRequest = new CreateEndpointRequest()  
        .withOutpostId("op-0d79779cef3c30a40")  
        .withSubnetId("subnet-8c7a57c5")  
        .withSecurityGroupId("sg-ab19e0d1")  
        .withAccessType("CustomerOwnedIp")  
        .withCustomerOwnedIpv4Pool("ipv4pool-coip-12345678901234567");  
    // Use .withAccessType and .withCustomerOwnedIpv4Pool only when the access type is
```

```
// customer-owned IP address pool (CoIP pool)
CreateEndpointResult createEndpointResult =
s3OutpostsClient.createEndpoint(createEndpointRequest);
System.out.println("Endpoint is created and its ARN is " +
createEndpointResult.getEndpointArn());
}
```

Viewing a list of your Amazon S3 on Outposts endpoints

To route requests to an Amazon S3 on Outposts access point, you must create and configure an S3 on Outposts endpoint. In order to create an endpoint, you will need an active connection with your service link to your Outposts home region. Each virtual private cloud (VPC) on your Outpost can have one associated endpoint. For more information about endpoint quotas, see [S3 on Outposts network requirements](#). You must create an endpoint to be able to access your Outposts buckets and perform object operations. For more information, see [Endpoints](#).

The following examples show you how to return a list of your S3 on Outposts endpoints by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts access points**.
3. On the **Outposts access points** page, choose the **Outposts endpoints** tab.
4. Under **Outposts endpoints**, you can view a list of your S3 on Outposts endpoints.

Using the AWS CLI

The following AWS CLI example lists the endpoints for the AWS Outposts resources that are associated with your account. For more information about this command, see [list-endpoints](#) in the [AWS CLI Reference](#).

```
aws s3outposts list-endpoints
```

Using the AWS SDK for Java

The following SDK for Java example lists the endpoints for an Outpost. For more information, see [ListEndpoints](#) in the [Amazon Simple Storage Service API Reference](#).

```
import com.amazonaws.services.s3outposts.AmazonS3Outposts;
```

```
import com.amazonaws.services.s3outposts.AmazonS3OutpostsClientBuilder;
import com.amazonaws.services.s3outposts.model.ListEndpointsRequest;
import com.amazonaws.services.s3outposts.model.ListEndpointsResult;

public void listEndpoints() {
    AmazonS3Outposts s3OutpostsClient = AmazonS3OutpostsClientBuilder
        .standard().build();

    ListEndpointsRequest listEndpointsRequest = new ListEndpointsRequest();
    ListEndpointsResult listEndpointsResult =
    s3OutpostsClient.listEndpoints(listEndpointsRequest);
    System.out.println("List endpoints result is " + listEndpointsResult);
}
```

Deleting an Amazon S3 on Outposts endpoint

To route requests to an Amazon S3 on Outposts access point, you must create and configure an S3 on Outposts endpoint. In order to create an endpoint, you will need an active connection with your service link to your Outposts home region. Each virtual private cloud (VPC) on your Outpost can have one associated endpoint. For more information about endpoint quotas, see [S3 on Outposts network requirements](#). You must create an endpoint to be able to access your Outposts buckets and perform object operations. For more information, see [Endpoints](#).

The following examples show you how to delete your S3 on Outposts endpoints by using the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts access points**.
3. On the **Outposts access points** page, choose the **Outposts endpoints** tab.
4. Under **Outposts endpoints**, choose the endpoint that you want to delete, and choose **Delete**.

Using the AWS CLI

The following AWS CLI example deletes an endpoint for an Outpost. To run this command, replace the *user input placeholders* with your own information.

```
aws s3outposts delete-endpoint --endpoint-id example-endpoint-id --outpost-
id op-01ac5d28a6a232904
```

Using the AWS SDK for Java

The following SDK for Java example deletes an endpoint for an Outpost. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.arn.Arn;
import com.amazonaws.services.s3outposts.AmazonS3Outposts;
import com.amazonaws.services.s3outposts.AmazonS3OutpostsClientBuilder;
import com.amazonaws.services.s3outposts.model.DeleteEndpointRequest;

public void deleteEndpoint(String endpointArnInput) {
    String outpostId = "op-01ac5d28a6a232904";
    AmazonS3Outposts s3OutpostsClient = AmazonS3OutpostsClientBuilder
        .standard().build();

    Arn endpointArn = Arn.fromString(endpointArnInput);
    String[] resourceParts = endpointArn.getResource().getResource().split("/");
    String endpointId = resourceParts[resourceParts.length - 1];
    DeleteEndpointRequest deleteEndpointRequest = new DeleteEndpointRequest()
        .withEndpointId(endpointId)
        .withOutpostId(outpostId);
    s3OutpostsClient.deleteEndpoint(deleteEndpointRequest);
    System.out.println("Endpoint with id " + endpointId + " is deleted.");
}
```

Working with S3 on Outposts objects

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API.

Objects are the fundamental entities stored in Amazon S3 on Outposts. Every object is contained in a bucket. You must use access points to access any object in an Outpost bucket. When you specify the bucket for object operations, you use the access point Amazon Resource Name (ARN) or the

access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

The following example shows the ARN format for S3 on Outposts access points, which includes the AWS Region code for the Region that the Outpost is homed to, the AWS account ID, the Outpost ID, and the access point name:

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/accesspoint/accesspoint-name
```

For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

Object ARNs use the following format, which includes the AWS Region that the Outpost is homed to, AWS account ID, Outpost ID, bucket name, and object key:

```
arn:aws:s3-outposts:us-west-2:123456789012:outpost/ op-01ac5d28a6a232904/bucket/DOC-EXAMPLE-BUCKET1/object/myobject
```

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your objects never leave your Outpost and are not in an AWS Region. Because the AWS Management Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

To upload an object, see [Step 4: Upload an object to an S3 on Outposts bucket](#). For other object actions, see the following topics.

Topics

- [Copying an object in an Amazon S3 on Outposts bucket using the AWS SDK for Java](#)
- [Getting an object from an Amazon S3 on Outposts bucket](#)
- [Listing the objects in an Amazon S3 on Outposts bucket](#)
- [Deleting objects in Amazon S3 on Outposts buckets](#)
- [Using HeadBucket to determine if an S3 on Outposts bucket exists and you have access permissions](#)
- [Performing and managing a multipart upload with the SDK for Java](#)
- [Using presigned URLs for S3 on Outposts](#)
- [Amazon S3 on Outposts with local Amazon EMR on Outposts](#)

Copying an object in an Amazon S3 on Outposts bucket using the AWS SDK for Java

Objects are the fundamental entities stored in Amazon S3 on Outposts. Every object is contained in a bucket. You must use access points to access any object in an Outpost bucket. When you specify the bucket for object operations, you use the access point Amazon Resource Name (ARN) or the access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

The following example shows the ARN format for S3 on Outposts access points, which includes the AWS Region code for the Region that the Outpost is homed to, the AWS account ID, the Outpost ID, and the access point name:

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/accesspoint/accesspoint-name
```

For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your objects never leave your Outpost and are not in an AWS Region. Because the AWS Management Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

The following example shows you how to copy an object in an S3 on Outposts bucket by using the AWS SDK for Java.

Using the AWS SDK for Java

The following S3 on Outposts example copies an object into a new object in the same bucket by using the SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.CopyObjectRequest;

public class CopyObject {
```

```
public static void main(String[] args) {
    String accessPointArn = "*** access point ARN ***";
    String sourceKey = "*** Source object key ***";
    String destinationKey = "*** Destination object key ***";

    try {
        // This code expects that you have AWS credentials set up per:
        // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-
credentials.html
        AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
            .enableUseArnRegion()
            .build();

        // Copy the object into a new object in the same bucket.
        CopyObjectRequest copyObjectRequest = new CopyObjectRequest(accessPointArn,
sourceKey, accessPointArn, destinationKey);
        s3Client.copyObject(copyObjectRequest);
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
}
```

Getting an object from an Amazon S3 on Outposts bucket

Objects are the fundamental entities stored in Amazon S3 on Outposts. Every object is contained in a bucket. You must use access points to access any object in an Outpost bucket. When you specify the bucket for object operations, you use the access point Amazon Resource Name (ARN) or the access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

The following example shows the ARN format for S3 on Outposts access points, which includes the AWS Region code for the Region that the Outpost is homed to, the AWS account ID, the Outpost ID, and the access point name:

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/accesspoint/accesspoint-name
```

For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your objects never leave your Outpost and are not in an AWS Region. Because the AWS Management Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

The following examples show you how to download (get) an object by using the AWS Command Line Interface (AWS CLI) and AWS SDK for Java.

Using the AWS CLI

The following example gets an object named sample-object.xml from an S3 on Outposts bucket (s3-outposts:GetObject) by using the AWS CLI. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [get-object](#) in the *AWS CLI Reference*.

```
aws s3api get-object --bucket arn:aws:s3-
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-
access-point --key testkey sample-object.xml
```

Using the AWS SDK for Java

The following S3 on Outposts example gets an object by using the SDK for Java. To use this example, replace each *user input placeholder* with your own information. For more information, see [GetObject](#) in the *Amazon Simple Storage Service API Reference*.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.GetObjectRequest;
import com.amazonaws.services.s3.model.ResponseHeaderOverrides;
import com.amazonaws.services.s3.model.S3Object;

import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
```

```
public class GetObject {  
    public static void main(String[] args) throws IOException {  
        String accessPointArn = "*** access point ARN ***";  
        String key = "*** Object key ***";  
  
        S3Object fullObject = null, objectPortion = null, headerOverrideObject = null;  
        try {  
            // This code expects that you have AWS credentials set up per:  
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-  
credentials.html  
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()  
                .enableUseArnRegion()  
                .build();  
  
            // Get an object and print its contents.  
            System.out.println("Downloading an object");  
            fullObject = s3Client.getObject(new GetObjectRequest(accessPointArn, key));  
            System.out.println("Content-Type: " +  
fullObject.getObjectMetadata().getContentType());  
            System.out.println("Content: ");  
            displayTextInputStream(fullObject.getObjectContent());  
  
            // Get a range of bytes from an object and print the bytes.  
            GetObjectRequest rangeObjectRequest = new GetObjectRequest(accessPointArn,  
key)  
                .withRange(0, 9);  
            objectPortion = s3Client.getObject(rangeObjectRequest);  
            System.out.println("Printing bytes retrieved.");  
            displayTextInputStream(objectPortion.getObjectContent());  
  
            // Get an entire object, overriding the specified response headers, and  
            print the object's content.  
            ResponseHeaderOverrides headerOverrides = new ResponseHeaderOverrides()  
                .withCacheControl("No-cache")  
                .withContentDisposition("attachment; filename=example.txt");  
            GetObjectRequest getObjectContextHeaderOverride = new  
GetObjectRequest(accessPointArn, key)  
                .withResponseHeaders(headerOverrides);  
            headerOverrideObject = s3Client.getObject(getObjectContextHeaderOverride);  
            displayTextInputStream(headerOverrideObject.getObjectContent());  
        } catch (AmazonServiceException e) {  
            // The call was transmitted successfully, but Amazon S3 couldn't process  
            // it, so it returned an error response.  
            e.printStackTrace();  
        }  
    }  
}
```

```
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        } finally {
            // To ensure that the network connection doesn't remain open, close any
            // open input streams.
            if (fullObject != null) {
                fullObject.close();
            }
            if (objectPortion != null) {
                objectPortion.close();
            }
            if (headerOverrideObject != null) {
                headerOverrideObject.close();
            }
        }
    }

private static void displayTextInputStream(InputStream input) throws IOException {
    // Read the text input stream one line at a time and display each line.
    BufferedReader reader = new BufferedReader(new InputStreamReader(input));
    String line = null;
    while ((line = reader.readLine()) != null) {
        System.out.println(line);
    }
    System.out.println();
}
```

Listing the objects in an Amazon S3 on Outposts bucket

Objects are the fundamental entities stored in Amazon S3 on Outposts. Every object is contained in a bucket. You must use access points to access any object in an Outpost bucket. When you specify the bucket for object operations, you use the access point Amazon Resource Name (ARN) or the access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

The following example shows the ARN format for S3 on Outposts access points, which includes the AWS Region code for the Region that the Outpost is homed to, the AWS account ID, the Outpost ID, and the access point name:

arn:aws:s3-outposts:*region:account-id*:outpost/*outpost-id*/accesspoint/*accesspoint-name*

For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

Note

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your objects never leave your Outpost and are not in an AWS Region. Because the AWS Management Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

The following examples show you how to list the objects in an S3 on Outposts bucket using the AWS CLI and AWS SDK for Java.

Using the AWS CLI

The following example lists the objects in an S3 on Outposts bucket (s3-outposts>ListObjectsV2) by using the AWS CLI. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [list-objects-v2](#) in the *AWS CLI Reference*.

```
aws s3api list-objects-v2 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-access-point
```

Note

When using this action with Amazon S3 on Outposts through the AWS SDKs, you provide the Outposts access point ARN in place of the bucket name, in the following form:

arn:aws:s3-outposts:*region:123456789012*:outpost/*op-01ac5d28a6a232904*/accesspoint/*example-Outposts-Access-Point*. For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

Using the AWS SDK for Java

The following S3 on Outposts example lists objects in a bucket by using the SDK for Java. To use this example, replace each *user input placeholder* with your own information.

Important

This example uses [ListObjectsV2](#), which is the latest revision of the ListObjects API operation. We recommend that you use this revised API operation for application development. For backward compatibility, Amazon S3 continues to support the prior version of this API operation.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.ListObjectsV2Request;
import com.amazonaws.services.s3.model.ListObjectsV2Result;
import com.amazonaws.services.s3.model.S3ObjectSummary;

public class ListObjectsV2 {

    public static void main(String[] args) {
        String accessPointArn = "*** access point ARN ***";

        try {
            // This code expects that you have AWS credentials set up per:
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-credentials.html
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .enableUseArnRegion()
                .build();

            System.out.println("Listing objects");

            // maxKeys is set to 2 to demonstrate the use of
            // ListObjectsV2Result.getNextContinuationToken()
            ListObjectsV2Request req = new
ListObjectsV2Request().withBucketName(accessPointArn).withMaxKeys(2);
            ListObjectsV2Result result;
```

```
do {
    result = s3Client.listObjectsV2(req);

    for (S3ObjectSummary objectSummary : result.getObjectSummaries()) {
        System.out.printf(" - %s (size: %d)\n", objectSummary.getKey(),
objectSummary.getSize());
    }
    // If there are more than maxKeys keys in the bucket, get a
continuation token
    // and list the next objects.
    String token = result.getNextContinuationToken();
    System.out.println("Next Continuation Token: " + token);
    req.setContinuationToken(token);
} while (result.isTruncated());
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Deleting objects in Amazon S3 on Outposts buckets

Objects are the fundamental entities stored in Amazon S3 on Outposts. Every object is contained in a bucket. You must use access points to access any object in an Outpost bucket. When you specify the bucket for object operations, you use the access point Amazon Resource Name (ARN) or the access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

The following example shows the ARN format for S3 on Outposts access points, which includes the AWS Region code for the Region that the Outpost is homed to, the AWS account ID, the Outpost ID, and the access point name:

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/accesspoint/accesspoint-name
```

For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your objects never leave your Outpost and are not in an AWS Region. Because the AWS Management Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

The following examples show you how to delete a single object or multiple objects in an S3 on Outposts bucket by using the AWS Command Line Interface (AWS CLI) and AWS SDK for Java.

Using the AWS CLI

The following examples show you how to delete a single object or multiple objects from an S3 on Outposts bucket.

delete-object

The following example deletes an object named sample-object.xml from an S3 on Outposts bucket (s3-outposts:DeleteObject) by using the AWS CLI. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [delete-object](#) in the *AWS CLI Reference*.

```
aws s3api delete-object --bucket arn:aws:s3-
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-
outposts-access-point --key sample-object.xml
```

delete-objects

The following example deletes two objects named sample-object.xml and test1.text from an S3 on Outposts bucket (s3-outposts:DeleteObject) by using the AWS CLI. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [delete-objects](#) in the *AWS CLI Reference*.

```
aws s3api delete-objects --bucket arn:aws:s3-
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-
outposts-access-point --delete file://delete.json
```

```
delete.json
{
```

```
"Objects": [
    {
        "Key": "test1.txt"
    },
    {
        "Key": "sample-object.xml"
    }
],
"Quiet": false
}
```

Using the AWS SDK for Java

The following examples show you how to delete a single object or multiple objects from an S3 on Outposts bucket.

DeleteObject

The following S3 on Outposts example deletes an object in a bucket by using the SDK for Java. To use this example, specify the access point ARN for the Outpost and the key name for the object that you want to delete. For more information, see [DeleteObject](#) in the *Amazon Simple Storage Service API Reference*.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.DeleteObjectRequest;

public class DeleteObject {
    public static void main(String[] args) {
        String accessPointArn = "*** access point ARN ***";
        String keyName = "*** key name ***";

        try {
            // This code expects that you have AWS credentials set up per:
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-credentials.html
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .enableUseArnRegion()
                .build();
        }
    }
}
```

```
s3Client.deleteObject(new DeleteObjectRequest(accessPointArn, keyName));
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

DeleteObjects

The following S3 on Outposts example uploads and then deletes objects in a bucket by using the SDK for Java. To use this example, specify the access point ARN for the Outpost. For more information, see [DeleteObjects](#) in the *Amazon Simple Storage Service API Reference*.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.DeleteObjectsRequest;
import com.amazonaws.services.s3.model.DeleteObjectsRequest.KeyVersion;
import com.amazonaws.services.s3.model.DeleteObjectsResult;

import java.util.ArrayList;

public class DeleteObjects {

    public static void main(String[] args) {
        String accessPointArn = "arn:aws:s3-
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-
outposts-access-point";

        try {
            // This code expects that you have AWS credentials set up per:
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-
credentials.html
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .enableUseArnRegion()
```

```
        .build();

        // Upload three sample objects.
        ArrayList<KeyVersion> keys = new ArrayList<KeyVersion>();
        for (int i = 0; i < 3; i++) {
            String keyName = "delete object example " + i;
            s3Client.putObject(accessPointArn, keyName, "Object number " + i + " to be deleted.");
            keys.add(new KeyVersion(keyName));
        }
        System.out.println(keys.size() + " objects successfully created.");

        // Delete the sample objects.
        DeleteObjectsRequest multiObjectDeleteRequest = new DeleteObjectsRequest(accessPointArn)
            .withKeys(keys)
            .withQuiet(false);

        // Verify that the objects were deleted successfully.
        DeleteObjectsResult delObjRes =
        s3Client.deleteObjects(multiObjectDeleteRequest);
        int successfulDeletes = delObjRes.getDeletedObjects().size();
        System.out.println(successfulDeletes + " objects successfully deleted.");
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process it, so it returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

Using HeadBucket to determine if an S3 on Outposts bucket exists and you have access permissions

Objects are the fundamental entities stored in Amazon S3 on Outposts. Every object is contained in a bucket. You must use access points to access any object in an Outpost bucket. When you specify

the bucket for object operations, you use the access point Amazon Resource Name (ARN) or the access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

The following example shows the ARN format for S3 on Outposts access points, which includes the AWS Region code for the Region that the Outpost is homed to, the AWS account ID, the Outpost ID, and the access point name:

```
arn:aws:s3-outposts:region:account-id:outpost/outpost-id/accesspoint/accesspoint-name
```

For more information about S3 on Outposts ARNs, see [Resource ARNs for S3 on Outposts](#).

Note

With Amazon S3 on Outposts, object data is always stored on the Outpost. When AWS installs an Outpost rack, your data stays local to your Outpost to meet data-residency requirements. Your objects never leave your Outpost and are not in an AWS Region.

Because the AWS Management Console is hosted in-Region, you can't use the console to upload or manage objects in your Outpost. However, you can use the REST API, AWS Command Line Interface (AWS CLI), and AWS SDKs to upload and manage your objects through your access points.

The following AWS Command Line Interface (AWS CLI) and AWS SDK for Java examples show you how to use the HeadBucket API operation to determine if an Amazon S3 on Outposts bucket exists and whether you have permission to access it. For more information, see [HeadBucket](#) in the [Amazon Simple Storage Service API Reference](#).

Using the AWS CLI

The following S3 on Outposts AWS CLI example uses the head-bucket command to determine if a bucket exists and you have permissions to access it. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [head-bucket](#) in the [AWS CLI Reference](#).

```
aws s3api head-bucket --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/accesspoint/example-outposts-access-point
```

Using the AWS SDK for Java

The following S3 on Outposts example shows how to determine if a bucket exists and if you have permission to access it. To use this example, specify the access point ARN for the Outpost. For more information, see [HeadBucket](#) in the *Amazon Simple Storage Service API Reference*.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.HeadBucketRequest;

public class HeadBucket {
    public static void main(String[] args) {
        String accessPointArn = "*** access point ARN ***";

        try {
            // This code expects that you have AWS credentials set up per:
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-credentials.html
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .enableUseArnRegion()
                .build();

            s3Client.headBucket(new HeadBucketRequest(accessPointArn));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Performing and managing a multipart upload with the SDK for Java

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use S3 on Outposts through the AWS Management

Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

The following examples show how you can use S3 on Outposts with the AWS SDK for Java to perform and manage a multipart upload.

Topics

- [Perform a multipart upload of an object in an S3 on Outposts bucket](#)
- [Copy a large object in an S3 on Outposts bucket by using multipart upload](#)
- [List parts of an object in an S3 on Outposts bucket](#)
- [Retrieve a list of in-progress multipart uploads in an S3 on Outposts bucket](#)

Perform a multipart upload of an object in an S3 on Outposts bucket

The following S3 on Outposts example initiates, uploads, and finishes a multipart upload of an object to a bucket by using the SDK for Java. To use this example, replace each *user input placeholder* with your own information. For more information, see [Uploading an object using multipart upload](#).

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.util.ArrayList;
import java.util.List;

public class MultipartUploadCopy {
    public static void main(String[] args) {
        String accessPointArn = "*** Source access point ARN ***";
        String sourceObjectKey = "*** Source object key ***";
        String destObjectKey = "*** Target object key ***";

        try {
            // This code expects that you have AWS credentials set up per:
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-credentials.html
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .enableUseArnRegion()
```

```
.build();

// Initiate the multipart upload.
InitiateMultipartUploadRequest initRequest = new
InitiateMultipartUploadRequest(accessPointArn, destObjectKey);
InitiateMultipartUploadResult initResult =
s3Client.initiateMultipartUpload(initRequest);

// Get the object size to track the end of the copy operation.
GetObjectMetadataRequest metadataRequest = new
GetObjectMetadataRequest(accessPointArn, sourceObjectKey);
ObjectMetadata metadataResult =
s3Client.getObjectMetadata(metadataRequest);
long objectSize = metadataResult.getContentLength();

// Copy the object using 5 MB parts.
long partSize = 5 * 1024 * 1024;
long bytePosition = 0;
int partNum = 1;
List<CopyPartResult> copyResponses = new ArrayList<CopyPartResult>();
while (bytePosition < objectSize) {
    // The last part might be smaller than partSize, so check to make sure
    // that lastByte isn't beyond the end of the object.
    long lastByte = Math.min(bytePosition + partSize - 1, objectSize - 1);

    // Copy this part.

        .withDestinationKey(destObjectKey)
        .withUploadId(initResult.getUploadId())
        .withFirstByte(bytePosition)
        .withLastByte(lastByte)
        .withPartNumber(partNum++);
    copyResponses.add(s3Client.copyPart(copyRequest));
    bytePosition += partSize;
}

// Complete the upload request to concatenate all uploaded parts and make
the copied object available.
CompleteMultipartUploadRequest completeRequest = new
CompleteMultipartUploadRequest(
    accessPointArn,
```

```
        destObjectKey,
        initResult.getUploadId(),
        getETags(copyResponses));
    s3Client.completeMultipartUpload(completeRequest);
    System.out.println("Multipart copy complete.");
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}

// This is a helper function to construct a list of ETags.
private static List<PartETag> getETags(List<CopyPartResult> responses) {
    List<PartETag> etags = new ArrayList<PartETag>();
    for (CopyPartResult response : responses) {
        etags.add(new PartETag(response.getPartNumber(), response.getETag()));
    }
    return etags;
}
```

Copy a large object in an S3 on Outposts bucket by using multipart upload

The following S3 on Outposts example uses the SDK for Java to copy an object in a bucket. To use this example, replace each *user input placeholder* with your own information. This example is adapted from [Copying an object using multipart upload](#).

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.util.ArrayList;
import java.util.List;

public class MultipartUploadCopy {
    public static void main(String[] args) {
        String accessPointArn = "*** Source access point ARN ***";
```

```
String sourceObjectKey = "*** Source object key ***";
String destObjectKey = "*** Target object key ***;

try {
    // This code expects that you have AWS credentials set up per:
    // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-
credentials.html
    AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
        .enableUseArnRegion()
        .build();

    // Initiate the multipart upload.
    InitiateMultipartUploadRequest initRequest = new
InitiateMultipartUploadRequest(accessPointArn, destObjectKey);
    InitiateMultipartUploadResult initResult =
s3Client.initiateMultipartUpload(initRequest);

    // Get the object size to track the end of the copy operation.
    GetObjectMetadataRequest metadataRequest = new
GetObjectMetadataRequest(accessPointArn, sourceObjectKey);
    ObjectMetadata metadataResult =
s3Client.getObjectMetadata(metadataRequest);
    long objectSize = metadataResult.getContentLength();

    // Copy the object using 5 MB parts.
    long partSize = 5 * 1024 * 1024;
    long bytePosition = 0;
    int partNum = 1;
    List<CopyPartResult> copyResponses = new ArrayList<CopyPartResult>();
    while (bytePosition < objectSize) {
        // The last part might be smaller than partSize, so check to make sure
        // that lastByte isn't beyond the end of the object.
        long lastByte = Math.min(bytePosition + partSize - 1, objectSize - 1);

        // Copy this part.
        CopyPartRequest copyRequest = new CopyPartRequest()
            .withSourceBucketName(accessPointArn)
            .withSourceKey(sourceObjectKey)
            .withDestinationBucketName(accessPointArn)
            .withDestinationKey(destObjectKey)
            .withUploadId(initResult.getUploadId())
            .withFirstByte(bytePosition)
            .withLastByte(lastByte)
            .withPartNumber(partNum++);
```

```
        copyResponses.add(s3Client.copyPart(copyRequest));
        bytePosition += partSize;
    }

    // Complete the upload request to concatenate all uploaded parts and make
    // the copied object available.
    CompleteMultipartUploadRequest completeRequest = new
    CompleteMultipartUploadRequest(
        accessPointArn,
        destObjectKey,
        initResult.getUploadId(),
        getETags(copyResponses));
    s3Client.completeMultipartUpload(completeRequest);
    System.out.println("Multipart copy complete.");

    }
    return etags;
}
}
```

List parts of an object in an S3 on Outposts bucket

The following S3 on Outposts example lists the parts of an object in a bucket by using the SDK for Java. To use this example, replace each *user input placeholder* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
```

```
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.util.List;

public class ListParts {
    public static void main(String[] args) {
        String accessPointArn = "*** access point ARN ***";
        String keyName = "*** Key name ***";
        String uploadId = "*** Upload ID ***";

        try {
            // This code expects that you have AWS credentials set up per:
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-
credentials.html
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .enableUseArnRegion()
                .build();

            ListPartsRequest listPartsRequest = new ListPartsRequest(accessPointArn,
keyName, uploadId);
            PartListing partListing = s3Client.listParts(listPartsRequest);
            List<PartSummary> partSummaries = partListing.getParts();

            System.out.println(partSummaries.size() + " multipart upload parts");
            for (PartSummary p : partSummaries) {
                System.out.println("Upload part: Part number = \\" + p.getPartNumber()
+ "\", ETag = " + p.getETag());
            }

        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Retrieve a list of in-progress multipart uploads in an S3 on Outposts bucket

The following S3 on Outposts example shows how to retrieve a list of the in-progress multipart uploads from an Outposts bucket by using the SDK for Java. To use this example, replace each *user input placeholder* with your own information. This example is adapted from the [Listing multipart uploads](#) example for Amazon S3.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.ListMultipartUploadsRequest;
import com.amazonaws.services.s3.model.MultipartUpload;
import com.amazonaws.services.s3.model.MultipartUploadListing;

import java.util.List;

public class ListMultipartUploads {
    public static void main(String[] args) {
        String accessPointArn = "*** access point ARN ***";

        try {
            // This code expects that you have AWS credentials set up per:
            // https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup-credentials.html
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .enableUseArnRegion()
                .build();

            // Retrieve a list of all in-progress multipart uploads.
            ListMultipartUploadsRequest allMultipartUploadsRequest = new
ListMultipartUploadsRequest(accessPointArn);
            MultipartUploadListing multipartUploadListing =
s3Client.listMultipartUploads(allMultipartUploadsRequest);
            List<MultipartUpload> uploads =
multipartUploadListing.getMultipartUploads();

            // Display information about all in-progress multipart uploads.
            System.out.println(uploads.size() + " multipart upload(s) in progress.");
            for (MultipartUpload u : uploads) {
                System.out.println("Upload in progress: Key = " + u.getKey() + "\",
id = " + u.getUploadId());
            }
        }
    }
}
```

```
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Using presigned URLs for S3 on Outposts

To grant time-limited access to objects that are stored locally on an Outpost without updating your bucket policy, you can use a presigned URL. With presigned URLs, you as the bucket owner can share objects with individuals in your virtual private cloud (VPC) or grant them the ability to upload or delete objects.

When you create a presigned URL by using the AWS SDKs or the AWS Command Line Interface (AWS CLI), you associate the URL with a specific action. You also grant time-limited access to the presigned URL by choosing a custom expiration time that can be as low as 1 second and as high as 7 days. When you share the presigned URL, the individual in the VPC can perform the action embedded in the URL as if they were the original signing user. When the URL reaches its expiration time, the URL expires and no longer works.

Limiting presigned URL capabilities

The capabilities of a presigned URL are limited by the permissions of the user who created it. In essence, presigned URLs are bearer tokens that grant access to those who possess them. As such, we recommend that you protect them appropriately.

AWS Signature Version 4 (SigV4)

To enforce specific behavior when presigned URL requests are authenticated by using AWS Signature Version 4 (SigV4), you can use condition keys in bucket policies and access point policies. For example, you can create a bucket policy that uses the `s3-outposts:signatureAge` condition to deny any Amazon S3 on Outposts presigned URL request on objects in the `example-outpost-bucket` bucket if the signature is more than 10 minutes old. To use this example, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Deny a presigned URL request if the signature is more than 10  
            minutes old",  
            "Effect": "Deny",  
            "Principal": {"AWS": "44445556666"},  
            "Action": "s3-outposts:*",  
            "Resource": "arn:aws:s3-outposts:us-  
east-1:111122223333:outpost/op-01ac5d28a6a232904/bucket/example-outpost-bucket/object/  
            *",  
            "Condition": {  
                "NumericGreaterThan": {"s3-outposts:signatureAge": 600000},  
                "StringEquals": {"s3-outposts:authType": "REST-QUERY-STRING"}  
            }  
        }  
    ]  
}
```

For a list of condition keys and additional example policies that you can use to enforce specific behavior when presigned URL requests are authenticated by using Signature Version 4, see [AWS Signature Version 4 \(SigV4\) authentication-specific policy keys](#).

Network path restriction

If you want to restrict the use of presigned URLs and all S3 on Outposts access to particular network paths, you can write policies that require a particular network path. To set the restriction on the IAM principal that makes the call, you can use identity-based AWS Identity and Access Management (IAM) policies (for example, user, group, or role policies). To set the restriction on the S3 on Outposts resource, you can use resource-based policies (for example, bucket and access point policies).

A network-path restriction on the IAM principal requires the user of those credentials to make requests from the specified network. A restriction on the bucket or access point requires that all requests to that resource originate from the specified network. These restrictions also apply outside of the presigned URL scenario.

The IAM global condition that you use depends on the type of endpoint. If you are using the public endpoint for S3 on Outposts, use `aws:SourceIp`. If you are using a VPC endpoint for S3 on Outposts, use `aws:SourceVpc` or `aws:SourceVpce`.

The following IAM policy statement requires the principal to access AWS only from the specified network range. With this policy statement, all access must originate from that range. This includes the case of someone who's using a presigned URL for S3 on Outposts. To use this example, replace the *user input placeholders* with your own information.

```
{  
    "Sid": "NetworkRestrictionForIAMPPrincipal",  
    "Effect": "Deny",  
    "Action": "*",  
    "Resource": "*",  
    "Condition": {  
        "NotIpAddressIfExists": {"aws:SourceIp": "IP-address-range"},  
        "BoolIfExists": {"aws:ViaAWSService": "false"}  
    }  
}
```

For an example bucket policy that uses the `aws:SourceIP` AWS global condition key to restrict access to an S3 on Outposts bucket to a specific network range, see [Setting up IAM with S3 on Outposts](#).

Who can create a presigned URL

Anyone with valid security credentials can create a presigned URL. But for a user in the VPC to successfully access an object, the presigned URL must be created by someone who has permission to perform the operation that the presigned URL is based upon.

You can use the following credentials to create a presigned URL:

- **IAM instance profile** – Valid up to 6 hours.
- **AWS Security Token Service** – Valid up to 36 hours when signed with permanent credentials, such as the credentials of the AWS account root user or an IAM user.
- **IAM user** – Valid up to 7 days when you're using AWS Signature Version 4.

To create a presigned URL that's valid for up to 7 days, first delegate IAM user credentials (the access key and secret key) to the SDK that you're using. Then, generate a presigned URL by using AWS Signature Version 4.

Note

- If you created a presigned URL by using a temporary token, the URL expires when the token expires, even if you created the URL with a later expiration time.
- Because presigned URLs grant access to your S3 on Outposts buckets to whoever has the URL, we recommend that you protect them appropriately. For more information about protecting presigned URLs, see [Limiting presigned URL capabilities](#).

When does S3 on Outposts check the expiration date and time of a presigned URL?

At the time of the HTTP request, S3 on Outposts checks the expiration date and time of a signed URL. For example, if a client begins to download a large file immediately before the expiration time, the download continues even if the expiration time passes during the download. However, if the connection drops and the client tries to restart the download after the expiration time passes, the download fails.

For more information about using a presigned URL to share or upload objects, see the following topics.

Topics

- [Sharing objects by using presigned URLs](#)
- [Generating a presigned URL to upload an object to an S3 on Outposts bucket](#)

Sharing objects by using presigned URLs

To grant time-limited access to objects that are stored locally on an Outpost without updating your bucket policy, you can use a presigned URL. With presigned URLs, you as the bucket owner can share objects with individuals in your virtual private cloud (VPC) or grant them the ability to upload or delete objects.

When you create a presigned URL by using the AWS SDKs or the AWS Command Line Interface (AWS CLI), you associate the URL with a specific action. You also grant time-limited access to the presigned URL by choosing a custom expiration time that can be as low as 1 second and as high as 7 days. When you share the presigned URL, the individual in the VPC can perform the action

embedded in the URL as if they were the original signing user. When the URL reaches its expiration time, the URL expires and no longer works.

When you create a presigned URL, you must provide your security credentials, and then specify the following:

- An access point Amazon Resource Name (ARN) for the Amazon S3 on Outposts bucket
- An object key
- An HTTP method (GET for downloading objects)
- An expiration date and time

A presigned URL is valid only for the specified duration. That is, you must start the action that's allowed by the URL before the expiration date and time. You can use a presigned URL multiple times, up to the expiration date and time. If you created a presigned URL by using a temporary token, then the URL expires when the token expires, even if you created the URL with a later expiration time.

Users in the virtual private cloud (VPC) who have access to the presigned URL can access the object. For example, if you have a video in your bucket and both the bucket and the object are private, you can share the video with others by generating a presigned URL. Because presigned URLs grant access to your S3 on Outposts buckets to whoever has the URL, we recommend that you protect these URLs appropriately. For more details about protecting presigned URLs, see [Limiting presigned URL capabilities](#).

Anyone with valid security credentials can create a presigned URL. However, the presigned URL must be created by someone who has permission to perform the operation that the presigned URL is based upon. For more information, see [Who can create a presigned URL](#).

You can generate a presigned URL to share an object in an S3 on Outposts bucket by using the AWS SDKs and the AWS CLI. For more information, see the following examples.

Using the AWS SDKs

You can use the AWS SDKs to generate a presigned URL that you can give to others so that they can retrieve an object.

Note

When you use the AWS SDKs to generate a presigned URL, the maximum expiration time for a presigned URL is 7 days from the time of creation.

Java

Example

The following example generates a presigned URL that you can give to others so that they can retrieve an object from an S3 on Outposts bucket. For more information, see [Using presigned URLs for S3 on Outposts](#). To use this example, replace the *user input placeholders* with your own information.

For instructions on creating and testing a working sample, see [Testing the Amazon S3 Java Code Examples](#).

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.HttpMethod;

import java.io.IOException;
import java.net.URL;
import java.time.Instant;

public class GeneratePresignedURL {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String accessPointArn = "*** access point ARN ***";
        String objectKey = "*** object key ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withRegion(clientRegion)
                .withCredentials(new ProfileCredentialsProvider())

```

```
        .build();

        // Set the presigned URL to expire after one hour.
        java.util.Date expiration = new java.util.Date();
        long expTimeMillis = Instant.now().toEpochMilli();
        expTimeMillis += 1000 * 60 * 60;
        expiration.setTime(expTimeMillis);

        // Generate the presigned URL.
        System.out.println("Generating pre-signed URL.");
        GeneratePresignedUrlRequest generatePresignedUrlRequest =
            new GeneratePresignedUrlRequest(accessPointArn, objectKey)
                .withMethod(HttpMethod.GET)
                .withExpiration(expiration);
        URL url = s3Client.generatePresignedUrl(generatePresignedUrlRequest);

        System.out.println("Pre-Signed URL: " + url.toString());
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't
        process
            // it, so it returned an error response.
            e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

.NET

Example

The following example generates a presigned URL that you can give to others so that they can retrieve an object from an S3 on Outposts bucket. For more information, see [Using presigned URLs for S3 on Outposts](#). To use this example, replace the *user input placeholders* with your own information.

For instructions on creating and testing a working sample, see [Running the Amazon S3 .NET Code Examples](#).

```
using Amazon;
```

```
using Amazon.S3;
using Amazon.S3.Model;
using System;

namespace Amazon.DocSamples.S3
{
    class GenPresignedURLTest
    {
        private const string accessPointArn = "*** access point ARN ***";
        private const string objectKey = "*** object key ***";
        // Specify how long the presigned URL lasts, in hours.
        private const double timeoutDuration = 12;
        // Specify your bucket Region (an example Region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            string urlString = GeneratePreSignedURL(timeoutDuration);
        }
        static string GeneratePreSignedURL(double duration)
        {
            string urlString = "";
            try
            {
                GetPreSignedUrlRequest request1 = new GetPreSignedUrlRequest
                {
                    BucketName = accessPointArn,
                    Key = objectKey,
                    Expires = DateTime.UtcNow.AddHours(duration)
                };
                urlString = s3Client.GetPreSignedURL(request1);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
        }
    }
}
```

```
        }
        return urlString;
    }
}
```

Python

The following example generates a presigned URL to share an object by using the SDK for Python (Boto3). For example, use a Boto3 client and the `generate_presigned_url` function to generate a presigned URL that allows you to GET an object.

```
import boto3
url = boto3.client('s3').generate_presigned_url(
    ClientMethod='get_object',
    Params={'Bucket': 'ACCESS_POINT_ARN', 'Key': 'OBJECT_KEY'},
    ExpiresIn=3600)
```

For more information about using the SDK for Python (Boto3) to generate a presigned URL, see [Python in the AWS SDK for Python \(Boto\) API Reference](#).

Using the AWS CLI

The following example AWS CLI command generates a presigned URL for an S3 on Outposts bucket. To use this example, replace the *user input placeholders* with your own information.

Note

When you use the AWS CLI to generate a presigned URL, the maximum expiration time for a presigned URL is 7 days from the time of creation.

```
aws s3 presign s3://arn:aws:s3-outposts:us-east-1:111122223333:outpost/op-01ac5d28a6a232904/accesspoint/example-outpost-access-point/mydoc.txt --expires-in 604800
```

For more information, see [presign](#) in the *AWS CLI Command Reference*.

Generating a presigned URL to upload an object to an S3 on Outposts bucket

To grant time-limited access to objects that are stored locally on an Outpost without updating your bucket policy, you can use a presigned URL. With presigned URLs, you as the bucket owner can share objects with individuals in your virtual private cloud (VPC) or grant them the ability to upload or delete objects.

When you create a presigned URL by using the AWS SDKs or the AWS Command Line Interface (AWS CLI), you associate the URL with a specific action. You also grant time-limited access to the presigned URL by choosing a custom expiration time that can be as low as 1 second and as high as 7 days. When you share the presigned URL, the individual in the VPC can perform the action embedded in the URL as if they were the original signing user. When the URL reaches its expiration time, the URL expires and no longer works.

When you create a presigned URL, you must provide your security credentials, and then specify the following:

- An access point Amazon Resource Name (ARN) for the Amazon S3 on Outposts bucket
- An object key
- An HTTP method (PUT for uploading objects)
- An expiration date and time

A presigned URL is valid only for the specified duration. That is, you must start the action that's allowed by the URL before the expiration date and time. You can use a presigned URL multiple times, up to the expiration date and time. If you created a presigned URL by using a temporary token, then the URL expires when the token expires, even if you created the URL with a later expiration time.

If the action allowed by a presigned URL consists of multiple steps, such as a multipart upload, you must start all steps before the expiration time. If S3 on Outposts tries to start a step with an expired URL, you receive an error.

Users in the virtual private cloud (VPC) who have access to the presigned URL can upload objects. For example, a user in the VPC who has access to the presigned URL can upload an object to your bucket. Because presigned URLs grant access to your S3 on Outposts bucket to any user in the VPC who has access to the presigned URL, we recommend that you protect these URLs appropriately. For more details about protecting presigned URLs, see [Limiting presigned URL capabilities](#).

Anyone with valid security credentials can create a presigned URL. However, the presigned URL must be created by someone who has permission to perform the operation that the presigned URL is based upon. For more information, see [Who can create a presigned URL](#).

Using the AWS SDKs to generate a presigned URL for an S3 on Outposts object operation

Java

SDK for Java 2.x

This example shows how to generate a presigned URL that you can use to upload an object to an S3 on Outposts bucket for a limited time. For more information, see [Using presigned URLs for S3 on Outposts](#).

```
public static void signBucket(S3Presigner presigner, String
outpostAccessPointArn, String keyName) {

    try {
        PutObjectRequest objectRequest = PutObjectRequest.builder()
            .bucket(accessPointArn)
            .key(keyName)
            .contentType("text/plain")
            .build();

        PutObjectPresignRequest presignRequest =
PutObjectPresignRequest.builder()
            .signatureDuration(Duration.ofMinutes(10))
            .putObjectRequest(objectRequest)
            .build();

        PresignedPutObjectRequest presignedRequest =
presigner.presignPutObject(presignRequest);

        String myURL = presignedRequest.url().toString();
        System.out.println("Presigned URL to upload a file to: " +myURL);
        System.out.println("Which HTTP method must be used when uploading a
file: " +
                    presignedRequest.httpRequest().method());

        // Upload content to the S3 on Outposts bucket by using this URL.
        URL url = presignedRequest.url();
    }
}
```

```
// Create the connection and use it to upload the new object by using  
// the presigned URL.  
HttpURLConnection connection = (HttpURLConnection)  
url.openConnection();  
connection.setDoOutput(true);  
connection.setRequestProperty("Content-Type", "text/plain");  
connection.setRequestMethod("PUT");  
OutputStreamWriter out = new  
OutputStreamWriter(connection.getOutputStream());  
out.write("This text was uploaded as an object by using a presigned  
URL.");  
out.close();  
  
connection.getResponseCode();  
System.out.println("HTTP response code is " +  
connection.getResponseCode());  
  
} catch (S3Exception e) {  
e.printStackTrace();  
} catch (IOException e) {  
e.printStackTrace();  
}  
}  
}
```

Python

SDK for Python (Boto3)

This example shows how to generate a presigned URL that can perform an S3 on Outposts action for a limited time. For more information, see [Using presigned URLs for S3 on Outposts](#). To make a request with the URL, use the Requests package.

```
import argparse  
import logging  
import boto3  
from botocore.exceptions import ClientError  
import requests  
  
logger = logging.getLogger(__name__)
```

```
def generate_presigned_url(s3_client, client_method, method_parameters,
                           expires_in):
    """
    Generate a presigned S3 on Outposts URL that can be used to perform an
    action.

    :param s3_client: A Boto3 Amazon S3 client.
    :param client_method: The name of the client method that the URL performs.
    :param method_parameters: The parameters of the specified client method.
    :param expires_in: The number of seconds that the presigned URL is valid for.
    :return: The presigned URL.
    """

    try:
        url = s3_client.generate_presigned_url(
            ClientMethod=client_method,
            Params=method_parameters,
            ExpiresIn=expires_in
        )
        logger.info("Got presigned URL: %s", url)
    except ClientError:
        logger.exception(
            "Couldn't get a presigned URL for client method '%s'.",
            client_method)
        raise
    return url

def usage_demo():
    logging.basicConfig(level=logging.INFO, format='%(levelname)s: %(message)s')

    print('*'*88)
    print("Welcome to the Amazon S3 on Outposts presigned URL demo.")
    print('*'*88)

    parser = argparse.ArgumentParser()
    parser.add_argument('accessPointArn', help="The name of the S3 on Outposts
access point ARN.")
    parser.add_argument(
        'key', help="For a GET operation, the key of the object in S3 on
Outposts. For a "
        "PUT operation, the name of a file to upload.")
    parser.add_argument(
        'action', choices=('get', 'put'), help="The action to perform.")
    args = parser.parse_args()
```

```
s3_client = boto3.client('s3')
client_action = 'get_object' if args.action == 'get' else 'put_object'
url = generate_presigned_url(
    s3_client, client_action, {'Bucket': args.accessPointArn, 'Key': args.key}, 1000)

print("Using the Requests package to send a request to the URL.")
response = None
if args.action == 'get':
    response = requests.get(url)
elif args.action == 'put':
    print("Putting data to the URL.")
    try:
        with open(args.key, 'r') as object_file:
            object_text = object_file.read()
            response = requests.put(url, data=object_text)
    except FileNotFoundError:
        print(f"Couldn't find {args.key}. For a PUT operation, the key must be the "
              f"name of a file that exists on your computer.")

if response is not None:
    print("Got response:")
    print(f"Status: {response.status_code}")
    print(response.text)

print('-'*88)

if __name__ == '__main__':
    usage_demo()
```

Amazon S3 on Outposts with local Amazon EMR on Outposts

Amazon EMR is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark, on AWS to process and analyze vast amounts of data. By using these frameworks and related open-source projects, you can process data for analytics purposes and business intelligence workloads. Amazon EMR also helps you transform and move large amounts of data into and out of other AWS data stores and databases, and supports Amazon

S3 on Outposts. For more information about Amazon EMR, see [Amazon EMR on Outposts](#) in the *Amazon EMR Management Guide*.

For Amazon S3 on Outposts, Amazon EMR started to support the Apache Hadoop S3A connector in version 7.0.0. Earlier versions of Amazon EMR don't support local S3 on Outposts, and the EMR File System (EMRFS) is not supported.

Supported applications

Amazon EMR with Amazon S3 on Outposts supports the following applications:

- Hadoop
- Spark
- Hue
- Hive
- Sqoop
- Pig
- Hudi
- Flink

For more information, see the [Amazon EMR Release Guide](#).

Create and configure an Amazon S3 on Outposts bucket

Amazon EMR uses the AWS SDK for Java with Amazon S3 on Outposts to store input data and output data. Your Amazon EMR log files are stored in a Regional Amazon S3 location that you select and aren't stored locally on the Outpost. For more information, see [Amazon EMR logs](#) in the *Amazon EMR Management Guide*.

To conform with Amazon S3 and DNS requirements, S3 on Outposts buckets have naming restrictions and limitations. For more information, see [Creating an S3 on Outposts bucket](#).

With Amazon EMR version 7.0.0 and later, you can use Amazon EMR with S3 on Outposts and the S3A file system.

Prerequisites

S3 on Outposts permissions – When you create your Amazon EMR instance profile, your role must contain the AWS Identity and Access Management (IAM) namespace for S3 on Outposts. S3 on

Outposts has its own namespace, s3-outposts*. For an example policy that uses this namespace, see [Setting up IAM with S3 on Outposts](#).

S3A connector – To configure your EMR cluster to access data from an Amazon S3 on Outposts bucket, you must use the Apache Hadoop S3A connector. To use the connector, ensure that all of your S3 URIs use the s3a scheme. If they don't, you can configure the file system implementation that you use for your EMR cluster so that your S3 URIs work with the S3A connector.

To configure the file system implementation to work with the S3A connector, you use the fs.*file_scheme*.impl and fs.AbstractFileSystem.*file_scheme*.impl configuration properties for your EMR cluster, where *file_scheme* corresponds to the type of S3 URIs that you have. To use the following example, replace the *user input placeholders* with your own information. For example, to change the file system implementation for S3 URIs that use the s3 scheme, specify the following cluster configuration properties:

```
[  
  {  
    "Classification": "core-site",  
    "Properties": {  
      "fs.s3.impl": "org.apache.hadoop.fs.s3a.S3AFFileSystem",  
      "fs.AbstractFileSystem.s3.impl": "org.apache.hadoop.fs.s3a.S3A"  
    }  
  }  
]
```

To use S3A, set the fs.*file_scheme*.impl configuration property to org.apache.hadoop.fs.s3a.S3AFFileSystem, and set the fs.AbstractFileSystem.*file_scheme*.impl property to org.apache.hadoop.fs.s3a.S3A.

For example, if you are accessing the path s3a://*bucket*/..., set the fs.s3a.impl property to org.apache.hadoop.fs.s3a.S3AFFileSystem, and set the fs.AbstractFileSystem.s3a.impl property to org.apache.hadoop.fs.s3a.S3A.

Getting started using Amazon EMR with Amazon S3 on Outposts

The following topics explain how to get started using Amazon EMR with Amazon S3 on Outposts.

Topics

- [Create a permissions policy](#)
- [Create and configure your cluster](#)
- [Configurations overview](#)
- [Considerations](#)

Create a permissions policy

Before you can create an EMR cluster that uses Amazon S3 on Outposts, you must create an IAM policy to attach to the Amazon EC2 instance profile for the cluster. The policy must have permissions to access the S3 on Outposts access point Amazon Resource Name (ARN). For more information about creating IAM policies for S3 on Outposts, see [Setting up IAM with S3 on Outposts](#).

The following example policy shows how to grant the required permissions. After you create the policy, attach the policy to the instance profile role that you use to create your EMR cluster, as described in the [the section called “Create and configure your cluster”](#) section. To use this example, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Resource": "arn:aws:s3-outposts:us-west-2:111122223333:outpost/op-01ac5d28a6a232904/accesspoint/access-point-name",  
            "Action": [  
                "s3-outposts:*"  
            ]  
        }  
    ]  
}
```

Create and configure your cluster

To create a cluster that runs Spark with S3 on Outposts, complete the following steps in the console.

To create a cluster that runs Spark with S3 on Outposts

1. Open the Amazon EMR console at <https://console.aws.amazon.com/elasticmapreduce/>.
2. In the left navigation pane, choose **Clusters**.
3. Choose **Create cluster**.
4. For **Amazon EMR release**, choose **emr-7.0.0 or later**.
5. For Application bundle, choose **Spark interactive**. Then select any other supported applications that you want to be included in your cluster.
6. To enable Amazon S3 on Outposts, enter your configuration settings.

Sample configuration settings

To use the following sample configuration settings, replace the *user input placeholders* with your own information.

```
[  
 {  
   "Classification": "core-site",  
   "Properties": {  
     "fs.s3a.bucket.DOC-EXAMPLE-BUCKET.accesspoint.arn": "arn:aws:s3-outposts:us-west-2:11122223333:outpost/op-01ac5d28a6a232904/accesspoint/access-point-name"  
     "fs.s3a.committer.name": "magic",  
     "fs.s3a.select.enabled": "false"  
   }  
 },  
 {  
   "Classification": "hadoop-env",  
   "Configurations": [  
     {  
       "Classification": "export",  
       "Properties": {  
         "JAVA_HOME": "/usr/lib/jvm/java-11-amazon-corretto.x86_64"  
       }  
     }  
   ],  
   "Properties": {}  
 },  
 {  
   "Classification": "spark-env",  
   "Configurations": [
```

```
{
    "Classification": "export",
    "Properties": {
        "JAVA_HOME": "/usr/lib/jvm/java-11-amazon-corretto.x86_64"
    }
},
],
"Properties": {}
},
{
    "Classification": "spark-defaults",
    "Properties": {
        "spark.executorEnv.JAVA_HOME": "/usr/lib/jvm/java-11-amazon-
corretto.x86_64",
        "spark.sql.sources.fastS3PartitionDiscovery.enabled": "false"
    }
}
]
```

- In the **Networking** section, choose a virtual private cloud (VPC) and subnet that are on your AWS Outposts rack. For more information about Amazon EMR on Outposts, see [EMR clusters on AWS Outposts](#) in the *Amazon EMR Management Guide*.
- In the **EC2 instance profile for Amazon EMR** section, choose the IAM role that has the [permissions policy that you created earlier](#) attached.
- Configure your remaining cluster settings, and then choose **Create cluster**.

Configurations overview

The following tables describe the S3A and Spark configurations and the values to specify for their parameters when you set up a cluster that uses S3 on Outposts with Amazon EMR.

S3A configurations

Parameter	Default value	Required value for S3 on Outposts	Explanation
fs.s3a.aw s.credent ials.provider	If not specified, S3A will look for S3 in Region bucket with	The access point ARN of the S3 on Outposts bucket	Amazon S3 on Outposts supports virtual private cloud (VPC)-only access

Parameter	Default value	Required value for S3 on Outposts	Explanation
	the Outposts bucket name.		points as the only means to access your Outposts buckets.
fs.s3a.committer.name	file	magic	Magic committer is the only supported committer for S3 on Outposts.
fs.s3a.select.enabled	TRUE	FALSE	S3 Select is not supported on Outposts.
JAVA_HOME	/usr/lib/jvm/java-8	/usr/lib/jvm/java-11-amazon-corretto.x86_64	S3 on Outposts on S3A requires Java version 11.

Spark configurations

Parameter	Default value	Required value for S3 on Outposts	Explanation
spark.sql.sources.fastS3PartitionDiscovery.enabled	TRUE	FALSE	S3 on Outposts doesn't support fast partition.
spark.executorEnv.JAVA_HOME	/usr/lib/jvm/java-8	/usr/lib/jvm/java-11-amazon-corretto.x86_64	S3 on Outposts on S3A requires Java version 11.

Considerations

Consider the following when you integrate Amazon EMR with S3 on Outposts buckets:

- Amazon S3 on Outposts is supported with Amazon EMR version 7.0.0 and later.
- The S3A connector is required to use S3 on Outposts with Amazon EMR. Only S3A has the features required to interact with S3 on Outposts buckets. For S3A connector setup information, see [Prerequisites](#).
- Amazon S3 on Outposts supports only server-side encryption with Amazon S3 managed keys (SSE-S3) with Amazon EMR. For more information, see [the section called “Data encryption”](#).
- Amazon S3 on Outposts doesn't support writes with the S3A FileOutputCommitter. Writes with the S3A FileOutputCommitter on S3 on Outposts buckets result in the following error: InvalidStorageClass: The storage class you specified is not valid.
- Amazon S3 on Outposts isn't supported with Amazon EMR Serverless or Amazon EMR on EKS.
- Amazon EMR logs are stored in a Regional Amazon S3 location that you select, and are not stored locally in the S3 on Outposts bucket.

Security in S3 on Outposts

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [AWS Compliance Programs](#). To learn about the compliance programs that apply to Amazon S3 on Outposts, see [AWS Services in Scope by Compliance Program](#).
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using S3 on Outposts. The following topics show you how to configure S3 on Outposts to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your S3 on Outposts resources.

Topics

- [Data encryption in S3 on Outposts](#)
- [AWS PrivateLink for S3 on Outposts](#)
- [AWS Signature Version 4 \(SigV4\) authentication-specific policy keys](#)
- [AWS managed policies for Amazon S3 on Outposts](#)
- [Using service-linked roles for Amazon S3 on Outposts](#)

Data encryption in S3 on Outposts

By default, all data stored in Amazon S3 on Outposts is encrypted by using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

You can optionally use server-side encryption with customer-provided encryption keys (SSE-C). To use SSE-C, specify an encryption key as part of your object API requests. Server-side encryption encrypts only the object data, not the object metadata. For more information, see [Using server-side encryption with customer-provided keys \(SSE-C\)](#).

 **Note**

S3 on Outposts doesn't support server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

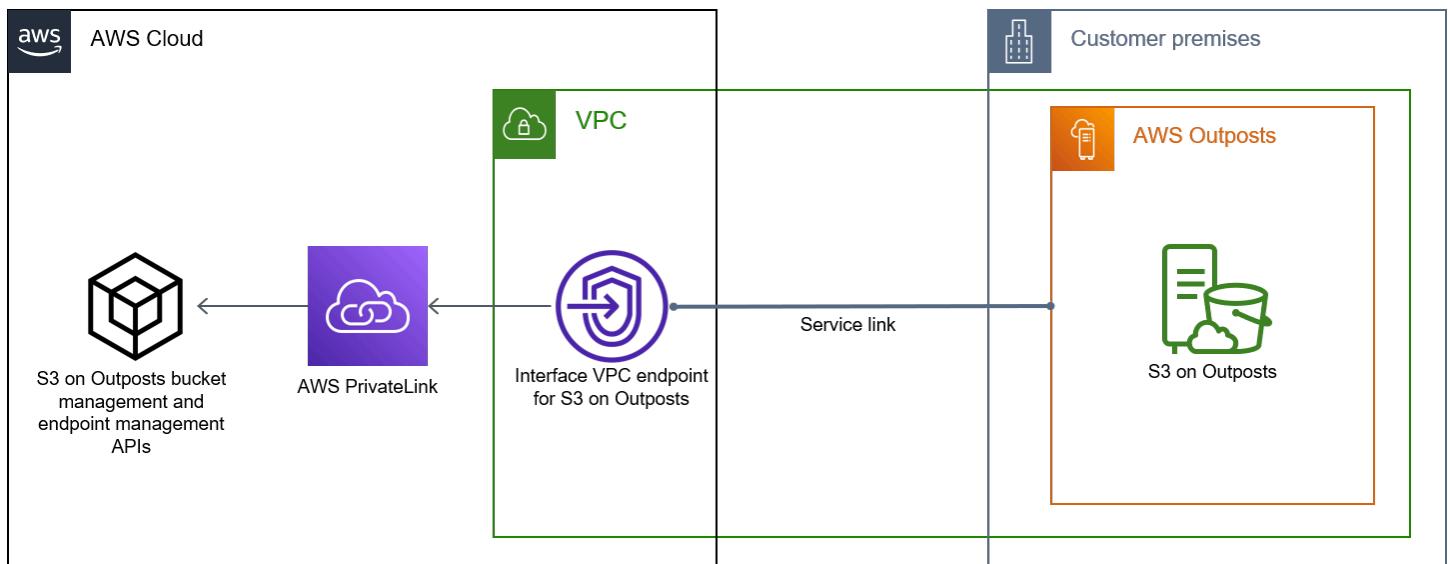

AWS PrivateLink for S3 on Outposts

S3 on Outposts supports AWS PrivateLink, which provides direct management access to your S3 on Outposts storage through a private endpoint within your virtual private network. This allows you to simplify your internal network architecture and perform management operations on your Outposts object storage by using private IP addresses in your Virtual Private Cloud (VPC). Using AWS PrivateLink eliminates the need to use public IP addresses or proxy servers.

With AWS PrivateLink for Amazon S3 on Outposts, you can provision *interface VPC endpoints* in your virtual private cloud (VPC) to access your S3 on Outposts [bucket management](#) and [endpoint management](#) APIs. Interface VPC endpoints are directly accessible from applications deployed in your VPC or on premises over your virtual private network (VPN) or AWS Direct Connect. You can access the bucket and endpoint management APIs through AWS PrivateLink. AWS PrivateLink doesn't support [data transfer](#) API operations, such as GET, PUT, and similar APIs. These operations are already transferred privately through the S3 on Outposts endpoint and access point configuration. For more information, see [Networking for S3 on Outposts](#).

Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your VPC. Requests made to interface endpoints for S3 on Outposts are automatically routed to S3 on Outposts bucket and endpoint management APIs on the AWS network. You can also access interface endpoints in your VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how to connect your VPC with your on-premises network, see the [AWS Direct Connect User Guide](#) and the [AWS Site-to-Site VPN User Guide](#).

Interface endpoints route requests for S3 on Outposts bucket and endpoint management APIs over the AWS network and through AWS PrivateLink, as illustrated in the following diagram.

For general information about interface endpoints, see [Interface VPC endpoints \(AWS PrivateLink\)](#) in the [AWS PrivateLink Guide](#).

Topics

- [Restrictions and limitations](#)
- [Accessing S3 on Outposts interface endpoints](#)

- [Updating an on-premises DNS configuration](#)
- [Creating a VPC endpoint for S3 on Outposts](#)
- [Creating bucket policies and VPC endpoint policies for S3 on Outposts](#)

Restrictions and limitations

When you access S3 on Outposts bucket and endpoint management APIs through AWS PrivateLink, VPC limitations apply. For more information, see [Interface endpoint properties and limitations](#) and [AWS PrivateLink quotas](#) in the *AWS PrivateLink Guide*.

In addition, AWS PrivateLink doesn't support the following:

- [Federal Information Processing Standard \(FIPS\) endpoints](#)
- [S3 on Outposts data transfer APIs](#), for example, GET, PUT, and similar object API operations.
- Private DNS

Accessing S3 on Outposts interface endpoints

To access S3 on Outposts bucket and endpoint management APIs using AWS PrivateLink, you *must* update your applications to use endpoint-specific DNS names. When you create an interface endpoint, AWS PrivateLink generates two types of endpoint-specific S3 on Outposts names: *Regional* and *zonal*.

- **Regional DNS names** – include a unique VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com`, for example, `vpce-1a2b3c4d-5e6f.s3-outposts.us-east-1.vpce.amazonaws.com`.
- **Zonal DNS names** – include a unique VPC endpoint ID, the Availability Zone, a service identifier, the AWS Region, and `vpce.amazonaws.com`, for example, `vpce-1a2b3c4d-5e6f-us-east-1a.s3-outposts.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use zonal DNS names for fault containment or to reduce Regional data transfer costs.

⚠ Important

S3 on Outposts interface endpoints are resolved from the public DNS domain. S3 on Outposts does not support private DNS. Use the `--endpoint-url` parameter for all bucket and endpoint management APIs.

AWS CLI examples

Use the `--region` and `--endpoint-url` parameters to access bucket management and endpoint management APIs through S3 on Outposts interface endpoints.

Example : Use the endpoint URL to list buckets with the S3 control API

In the following example, replace the Region `us-east-1`, VPC endpoint URL `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com`, and account ID `111122223333` with appropriate information.

```
aws s3control list-regional-buckets --region us-east-1 --endpoint-url  
https://vpce-1a2b3c4d-5e6f.s3-outposts.us-east-1.vpce.amazonaws.com --account-  
id 111122223333
```

AWS SDK examples

Update your SDKs to the latest version, and configure your clients to use an endpoint URL for accessing the S3 control API for S3 on Outposts interface endpoints. For more information, see [AWS SDK examples for AWS PrivateLink](#).

SDK for Python (Boto3)

Example : Use an endpoint URL to access the S3 control API

In the following example, replace the Region `us-east-1` and VPC endpoint URL `vpce-1a2b3c4d-5e6f.s3-outposts.us-east-1.vpce.amazonaws.com` with appropriate information.

```
control_client = session.client(  
    service_name='s3control',  
    region_name='us-east-1',  
    endpoint_url='https://vpce-1a2b3c4d-5e6f.s3-outposts.us-east-1.vpce.amazonaws.com'  
)
```

For more information, see [AWS PrivateLink for Amazon S3](#) in the *Boto3 developer guide*.

SDK for Java 2.x

Example : Use an endpoint URL to access the S3 control API

In the following example, replace the VPC endpoint URL `vpce-1a2b3c4d-5e6f.s3-outposts.us-east-1.vpce.amazonaws.com` and the Region `Region.US_EAST_1` with appropriate information.

```
// control client
Region region = Region.US_EAST_1;
S3ControlClient s3ControlClient = S3ControlClient.builder().region(region)

.endpointOverride(URI.create("https://vpce-1a2b3c4d-5e6f.s3-outposts.us-
east-1.vpce.amazonaws.com"))
.build()
```

For more information, see [S3ControlClient](#) in the *AWS SDK for Java API Reference*.

Updating an on-premises DNS configuration

When using endpoint-specific DNS names to access the interface endpoints for S3 on Outposts bucket management and endpoint management APIs, you don't have to update your on-premises DNS resolver. You can resolve the endpoint-specific DNS name with the private IP address of the interface endpoint from the public S3 on Outposts DNS domain.

Creating a VPC endpoint for S3 on Outposts

To create a VPC interface endpoint for S3 on Outposts, see [Create a VPC endpoint](#) in the *AWS PrivateLink Guide*.

Creating bucket policies and VPC endpoint policies for S3 on Outposts

You can attach an endpoint policy to your VPC endpoint that controls access to S3 on Outposts. You can also use the `aws:sourceVpce` condition in S3 on Outposts bucket policies to restrict access to specific buckets from a specific VPC endpoint. With VPC endpoint policies, you can control access to S3 on Outposts bucket management APIs and endpoint management APIs. With bucket policies, you can control access to the S3 on Outposts bucket management APIs. However, you can't manage access to object actions for S3 on Outposts using `aws:sourceVpce`.

Access policies for S3 on Outposts specify the following information:

- The AWS Identity and Access Management (IAM) principal for which actions are allowed or denied.
- The S3 control actions that are allowed or denied.
- The S3 on Outposts resources on which actions are allowed or denied.

The following examples show policies that restrict access to a bucket or to an endpoint. For more information about VPC connectivity, see [Network-to-VPC connectivity options](#) in the AWS whitepaper [Amazon Virtual Private Cloud Connectivity Options](#).

Important

- When you apply the example policies for VPC endpoints described in this section, you might block your access to the bucket without intending to do so. Bucket permissions that limit bucket access to connections originating from your VPC endpoint can block all connections to the bucket. For information about how to fix this issue, see [My bucket policy has the wrong VPC or VPC endpoint ID. How can I fix the policy so that I can access the bucket?](#) in the AWS Support Knowledge Center.
- Before using the following example bucket policies, replace the VPC endpoint ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
- If your policy only allows access to an S3 on Outposts bucket from a specific VPC endpoint, it disables console access for that bucket because console requests don't originate from the specified VPC endpoint.

Topics

- [Example: Restricting access to a specific bucket from a VPC endpoint](#)
- [Example: Denying access from a specific VPC endpoint in an S3 on Outposts bucket policy](#)

Example: Restricting access to a specific bucket from a VPC endpoint

You can create an endpoint policy that restricts access to specific S3 on Outposts buckets only. The following policy restricts access for the GetBucketPolicy action only to the *example-outpost-bucket*. To use this policy, replace the example values with your own.

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1415115909151",  
    "Statement": [  
        { "Sid": "Access-to-specific-bucket-only",  
            "Principal": {"AWS":"111122223333"},  
            "Action": "s3-outposts:GetBucketPolicy",  
            "Effect": "Allow",  
            "Resource": "arn:aws:s3-  
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outpost-  
bucket"  
        }  
    ]  
}
```

Example: Denying access from a specific VPC endpoint in an S3 on Outposts bucket policy

The following S3 on Outposts bucket policy denies access to GetBucketPolicy on the *example-outpost-bucket* bucket through the *vpce-1a2b3c4d* VPC endpoint.

The aws:sourceVpce condition specifies the endpoint and does not require an Amazon Resource Name (ARN) for the VPC endpoint resource, only the endpoint ID. To use this policy, replace the example values with your own.

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1415115909152",  
    "Statement": [  
        {  
            "Sid": "Deny-access-to-specific-VPCE",  
            "Principal": {"AWS":"111122223333"},  
            "Action": "s3-outposts:GetBucketPolicy",  
            "Effect": "Deny",  
            "Resource": "arn:aws:s3-  
outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outpost-  
bucket",  
            "Condition": {  
                "StringEquals": {"aws:sourceVpce": "vpce-1a2b3c4d"}  
            }  
        }  
    ]  
}
```

AWS Signature Version 4 (SigV4) authentication-specific policy keys

The following table shows the condition keys related to AWS Signature Version 4 (SigV4) authentication that you can use with Amazon S3 on Outposts. In a bucket policy, you can add these conditions to enforce specific behavior when requests are authenticated by using Signature Version 4. For example policies, see [Bucket policy examples that use Signature Version 4-related condition keys](#). For more information about authenticating requests using Signature Version 4, see [Authenticating requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*

Applicable keys for s3-outposts : * actions or any of the S3 on Outposts actions

Applicable keys	Description
s3-outpos ts:authType	<p>S3 on Outposts supports various methods of authentication. To restrict incoming requests to use a specific authentication method, you can use this optional condition key. For example, you can use this condition key to allow only the HTTP Authorization header to be used in request authentication.</p> <p>Valid values:</p> <p>REST-HEADER</p> <p>REST-QUERY-STRING</p>
s3-outpos ts:signatureAge	<p>The length of time, in milliseconds, that a signature is valid in an authenticated request.</p> <p>This condition works only for presigned URLs.</p> <p>In Signature Version 4, the signing key is valid for up to seven days. Therefore, the signatures are also valid for up to seven days. For more information, see Introduction to signing requests in the <i>Amazon Simple Storage Service API Reference</i>. You can use this condition to further limit the signature age.</p> <p>Example value: 600000</p>

Applicable keys	Description
s3-outposts:x-amz-content-sha256	<p>You can use this condition key to disallow unsigned content in your bucket.</p> <p>When you use Signature Version 4, for requests that use the Authorization header, you add the x-amz-content-sha256 header in the signature calculation and then set its value to the hash payload.</p> <p>You can use this condition key in your bucket policy to deny any uploads where the payloads are not signed. For example:</p> <ul style="list-style-type: none">Deny uploads that use the Authorization header to authenticate requests but don't sign the payload. For more information, see Transferring payload in a single chunk in the <i>Amazon Simple Storage Service API Reference</i>.Deny uploads that use presigned URLs. Presigned URLs always have an UNSIGNED_PAYLOAD . For more information, see Authenticating requests and Authentication methods in the <i>Amazon Simple Storage Service API Reference</i>. <p>Valid value: UNSIGNED-PAYLOAD</p>

Bucket policy examples that use Signature Version 4-related condition keys

To use the following examples, replace the *user input placeholders* with your own information.

Example : s3-outposts:signatureAge

The following bucket policy denies any S3 on Outposts presigned URL request on objects in example-outpost-bucket if the signature is more than 10 minutes old.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {
```

```
        "Sid": "Deny a presigned URL request if the signature is more than 10
minutes old",
        "Effect": "Deny",
        "Principal": {"AWS":"444455556666"},
        "Action": "s3-outposts:*",
        "Resource": "arn:aws:s3-outposts:us-
east-1:111122223333:outpost/op-01ac5d28a6a232904/bucket/example-outpost-bucket/object/*
",
        "Condition": {
            "NumericGreaterThan": {"s3-outposts:signatureAge": 600000},
            "StringEquals": {"s3-outposts:authType": "REST-QUERY-STRING"}
        }
    }
}
```

Example : s3-outposts:authType

The following bucket policy allows only requests that use the Authorization header for request authentication. Any presigned URL requests will be denied since presigned URLs use query parameters to provide request and authentication information. For more information, see [Authentication methods](#) in the *Amazon Simple Storage Service API Reference*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow only requests that use the Authorization header for
request authentication. Deny presigned URL requests.",
            "Effect": "Deny",
            "Principal": {"AWS":"111122223333"},
            "Action": "s3-outposts:*",
            "Resource": "arn:aws:s3-outposts:us-
east-1:111122223333:outpost/op-01ac5d28a6a232904/bucket/example-outpost-bucket/object/*
",
            "Condition": {
                "StringNotEquals": {
                    "s3-outposts:authType": "REST-HEADER"
                }
            }
        }
    ]
}
```

{

Example : s3-outposts:x-amz-content-sha256

The following bucket policy denies any uploads with unsigned payloads, such as uploads that are using presigned URLs. For more information, see [Authenticating requests](#) and [Authentication methods](#) in the *Amazon Simple Storage Service API Reference*.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Deny uploads with unsigned payloads.",  
            "Effect": "Deny",  
            "Principal": {"AWS": "111122223333"},  
            "Action": "s3-outposts:*",  
            "Resource": "arn:aws:s3-outposts:us-  
east-1:111122223333:outpost/op-01ac5d28a6a232904/bucket/example-outpost-bucket/object/  
*",  
            "Condition": {  
                "StringEquals": {  
                    "s3-outposts:x-amz-content-sha256": "UNSIGNED-PAYLOAD"  
                }  
            }  
        }  
    ]  
}
```

AWS managed policies for Amazon S3 on Outposts

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining [customer managed policies](#) that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users,

groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see [AWS managed policies](#) in the *IAM User Guide*.

AWS managed policy: AWSS3OnOutpostsServiceRolePolicy

Helps manage network resources for you as part of the service-linked role AWSServiceRoleForS3OnOutposts.

To view the permissions for this policy, see [AWSS3OnOutpostsServiceRolePolicy](#).

S3 on Outposts updates to AWS managed policies

View details about updates to AWS managed policies for S3 on Outposts since this service began tracking these changes.

Change	Description	Date
S3 on Outposts added AWSS3OnOutpostsServiceRolePolicy	S3 on Outposts added AWSS3OnOutpostsServiceRolePolicy as part of the service-linked role AWSServiceRoleForS3OnOutposts , which helps manage network resources for you.	October 3, 2023
S3 on Outposts started tracking changes	S3 on Outposts started tracking changes for its AWS managed policies.	October 3, 2023

Using service-linked roles for Amazon S3 on Outposts

Amazon S3 on Outposts uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to S3 on Outposts. Service-linked roles are predefined by S3 on Outposts and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up S3 on Outposts easier because you don't have to manually add the necessary permissions. S3 on Outposts defines the permissions of its service-linked roles, and unless defined otherwise, only S3 on Outposts can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your S3 on Outposts resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS Services That Work with IAM](#) and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for S3 on Outposts

S3 on Outposts uses the service-linked role named **AWSServiceRoleForS3OnOutposts** to help manage network resources for you.

The **AWSServiceRoleForS3OnOutposts** service-linked role trusts the following services to assume the role:

- `s3-outposts.amazonaws.com`

The role permissions policy named **AWSS3OnOutpostsServiceRolePolicy** allows S3 on Outposts to complete the following actions on the specified resources:

```
{  
    "Version": "2012-10-17",  
    "Statement": [{  
        "Effect": "Allow",  
        "Action": [  
            "ec2:DescribeSubnets",  
            "ec2:DescribeSecurityGroups",  
            "ec2:DescribeNetworkInterfaces",  
            "ec2:DescribeVpcs",  
            "ec2:DescribeCoipPools",  
            "ec2:GetCoipPoolUsage",  
            "ec2:DescribeAddresses",  
            "ec2:DescribeLocalGatewayRouteTableVpcAssociations"  
        ],  
    }]
```

```
        "Resource": "*",
        "Sid": "DescribeVpcResources"
    },
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface"
    ],
    "Resource": [
        "arn:aws:ec2:*::subnet/*",
        "arn:aws:ec2:*::security-group/*"
    ],
    "Sid": "CreateNetworkInterface"
},
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface"
    ],
    "Resource": [
        "arn:aws:ec2:*::network-interface/*"
    ],
    "Condition": {
        "StringEquals": {
            "aws:RequestTag/CreatedBy": "S3 On Outposts"
        }
    },
    "Sid": "CreateTagsForCreateNetworkInterface"
},
{
    "Effect": "Allow",
    "Action": [
        "ec2:AllocateAddress"
    ],
    "Resource": [
        "arn:aws:ec2:*::ipv4pool-ec2/*"
    ],
    "Sid": "AllocateIpAddress"
},
{
    "Effect": "Allow",
    "Action": [
        "ec2:AllocateAddress"
    ],
```

```
"Resource": [
    "arn:aws:ec2:*::elastic-ip/*"
],

    "StringEquals": {
        "aws:RequestTag/CreatedBy": "S3 On Outposts"
    }
},
"Sid": "CreateTagsForAllocateIpAddress"
},
{
    "Effect": "Allow",
    "Action": [
        "ec2:ModifyNetworkInterfaceAttribute",
        "ec2>CreateNetworkInterfacePermission",
        "ec2>DeleteNetworkInterface",
        "ec2>DeleteNetworkInterfacePermission",
        "ec2:DisassociateAddress",
        "ec2:ReleaseAddress",
        "ec2:AssociateAddress"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/CreatedBy": "S3 On Outposts"
        }
    },
    "Sid": "ReleaseVpcResources"
},
{
    "Effect": "Allow",
    "Action": [
        "ec2>CreateTags"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "ec2>CreateAction": [
                "CreateNetworkInterface",
                "AllocateAddress"
            ],
            "aws:RequestTag/CreatedBy": [
                "S3 On Outposts"
            ]
        }
    }
}
```

```
        }
    },
    "Sid": "CreateTags"
}
]
```

You must configure permissions to allow an IAM entity (such as a role) to create, edit, or delete a service-linked role. For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

Creating a service-linked role for S3 on Outposts

You don't need to manually create a service-linked role. When you create an S3 on Outposts endpoint in the AWS Management Console, the AWS CLI, or the AWS API, S3 on Outposts creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create an S3 on Outposts endpoint, S3 on Outposts creates the service-linked role for you again.

You can also use the IAM console to create a service-linked role with the **S3 on Outposts** use case. In the AWS CLI or the AWS API, create a service-linked role with the `s3-outposts.amazonaws.com` service name. For more information, see [Creating a service-linked role](#) in the *IAM User Guide*. If you delete this service-linked role, you can use this same process to create the role again.

Editing a service-linked role for S3 on Outposts

S3 on Outposts does not allow you to edit the `AWSServiceRoleForS3onOutposts` service-linked role. This includes the name of the role because various entities might reference it. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

Deleting a service-linked role for S3 on Outposts

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

Note

If the S3 on Outposts service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete S3 on Outposts resources used by the AWSServiceRoleForS3OnOutposts role

1. [Delete the S3 on Outposts endpoints](#) in your AWS account across all AWS Regions.
2. Delete the service-linked role using IAM.

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForS3OnOutposts service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

Supported Regions for S3 on Outposts service-linked roles

S3 on Outposts supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see [S3 on Outposts Regions and endpoints](#).

Managing S3 on Outposts storage

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

For more information about managing and sharing your Amazon S3 on Outposts storage capacity, see the following topics.

Topics

- [Managing S3 Versioning for your S3 on Outposts bucket](#)

- [Creating and managing a lifecycle configuration for your Amazon S3 on Outposts bucket](#)
- [Replicating objects for S3 on Outposts](#)
- [Sharing S3 on Outposts by using AWS RAM](#)
- [Other AWS services that use S3 on Outposts](#)

Managing S3 Versioning for your S3 on Outposts bucket

When enabled, S3 Versioning saves multiple distinct copies of an object in the same bucket. You can use S3 Versioning to preserve, retrieve, and restore every version of every object stored in your Outposts buckets. S3 Versioning helps you recover from unintended user actions and application failures.

Amazon S3 on Outposts buckets have three versioning states:

- **Unversioned** – If you've never enabled or suspended S3 Versioning on your bucket, it is unversioned and returns no S3 Versioning status. For more information about S3 Versioning, see [Using versioning in S3 buckets](#).
- **Enabled** – Enables S3 Versioning for the objects in the bucket. All objects added to the bucket receive a unique version ID. Objects that already existed in the bucket at the time that you enable versioning have a version ID of null. If you modify these (or any other) objects with other operations, such as [PutObject](#), the new objects get a unique version ID.
- **Suspended** – Suspends S3 Versioning for the objects in the bucket. All objects added to the bucket after versioning is suspended receive the version ID null. For more information, see [Adding objects to versioning-suspended buckets](#).

After you enable S3 Versioning for an S3 on Outposts bucket, it can never return to an unversioned state. However, you can suspend versioning. For more information about S3 Versioning, see [Using versioning in S3 buckets](#).

For each object in your bucket, you have a current version and zero or more noncurrent versions. To reduce storage costs, you can configure your bucket S3 Lifecycle rules to expire noncurrent versions after a specified time period. For more information, see [Creating and managing a lifecycle configuration for your Amazon S3 on Outposts bucket](#).

The following examples show you how to enable or suspend versioning for an existing S3 on Outposts bucket by using the AWS Management Console and the AWS Command Line Interface (AWS CLI). To create a bucket with S3 Versioning enabled, see [Creating an S3 on Outposts bucket](#).

Note

The AWS account that creates the bucket owns it and is the only one that can commit actions to it. Buckets have configuration properties, such as Outpost, tag, default encryption, and access point settings. The access point settings include the virtual private cloud (VPC), the access point policy for accessing the objects in the bucket, and other metadata. For more information, see [S3 on Outposts specifications](#).

Using the S3 console

To edit the S3 Versioning settings for your bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket that you want to enable S3 Versioning for.
4. Choose the **Properties** tab.
5. Under **Bucket Versioning**, choose **Edit**.
6. Edit the S3 Versioning settings for the bucket by choosing one of the following options:
 - To suspend S3 Versioning and stop the creation of new object versions, choose **Suspend**.
 - To enable S3 Versioning and save multiple distinct copies of each object, choose **Enable**.
7. Choose **Save changes**.

Using the AWS CLI

To enable or suspend S3 Versioning for your bucket by using the AWS CLI, use the `put-bucket-versioning` command, as shown in the following examples. To use these examples, replace each *user input placeholder* with your own information.

For more information, see [put-bucket-versioning](#) in the *AWS CLI Reference*.

Example : To enable S3 Versioning

```
aws s3control put-bucket-versioning --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket --versioning-configuration Status=Enabled
```

Example : To suspend S3 Versioning

```
aws s3control put-bucket-versioning --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/bucket/example-outposts-bucket --versioning-configuration Status=Suspended
```

Creating and managing a lifecycle configuration for your Amazon S3 on Outposts bucket

You can use S3 Lifecycle to optimize storage capacity for Amazon S3 on Outposts. You can create lifecycle rules to expire objects as they age or are replaced by newer versions. You can create, enable, disable, or delete a lifecycle rule.

For more information about S3 Lifecycle, see [Managing your storage lifecycle](#).

Note

The AWS account that creates the bucket owns it and is the only one that can create, enable, disable, or delete a lifecycle rule.

To create and manage the lifecycle configuration for your S3 on Outposts bucket, see the following topics.

Topics

- [Creating and managing a lifecycle rule by using the AWS Management Console](#)
- [Creating and managing a lifecycle configuration by using the AWS CLI and SDK for Java](#)

Creating and managing a lifecycle rule by using the AWS Management Console

You can use S3 Lifecycle to optimize storage capacity for Amazon S3 on Outposts. You can create lifecycle rules to expire objects as they age or are replaced by newer versions. You can create, enable, disable, or delete a lifecycle rule.

For more information about S3 Lifecycle, see [Managing your storage lifecycle](#).

Note

The AWS account that creates the bucket owns it and is the only one that can create, enable, disable, or delete a lifecycle rule.

To create and manage a lifecycle rule for an S3 on Outposts by using the AWS Management Console, see the following topics.

Topics

- [Creating a lifecycle rule](#)
- [Enabling a lifecycle rule](#)
- [Editing a lifecycle rule](#)
- [Deleting a lifecycle rule](#)

Creating a lifecycle rule

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket that you want to create a lifecycle rule for.
4. Choose the **Management** tab, and then choose **Create Lifecycle rule**.
5. Enter a value for **Lifecycle rule name**.
6. Under **Rule scope**, choose one of the following options:
 - To limit the scope to specific filters, choose **Limit the scope of this rule using one or more filters**. Then, add a prefix filter, tags, or object size.

- To apply the rule to all objects in the bucket, choose **Apply to all objects in the bucket**.
7. Under **Lifecycle rule actions**, choose one of the following options:
- **Expire current versions of objects** – For versioning-enabled buckets, S3 on Outposts adds a delete marker and retains the objects as noncurrent versions. For buckets that don't use S3 Versioning, S3 on Outposts permanently deletes the objects.
 - **Permanently delete noncurrent versions of objects** – S3 on Outposts permanently deletes noncurrent versions of objects.
 - **Delete expired object delete markers or incomplete multipart uploads** – S3 on Outposts permanently deletes expired object delete markers or incomplete multipart uploads.

If you limit the scope of your Lifecycle rule by using object tags, you can't choose **Delete expired object delete markers**. You also can't choose **Delete expired object delete markers** if you choose **Expire current object versions**.

 **Note**

Size-based filters can't be used with delete markers and incomplete multipart uploads.

8. If you chose **Expire current versions of objects** or **Permanently delete noncurrent versions of objects**, configure the rule trigger based on a specific date or the object's age.
9. If you chose **Delete expired object delete markers**, to confirm that you want to delete expired object delete markers, select **Delete expired object delete markers**.
10. Under **Timeline Summary**, review your Lifecycle rule, and choose **Create rule**.

Enabling a lifecycle rule

To enable or disable a bucket lifecycle rule

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket that you want to enable or disable a lifecycle rule for.
4. Choose the **Management** tab, and then under **Lifecycle rule**, choose the rule that you want to enable or disable.
5. For **Action**, choose **Enable or disable rule**.

Editing a lifecycle rule

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket that you want to edit a lifecycle rule for.
4. Choose the **Management** tab, and then choose the **Lifecycle rule** that you want to edit.
5. (Optional) Update the value for **Lifecycle rule name**.
6. Under **Rule scope**, edit the scope as needed:
 - To limit the scope to specific filters, choose **Limit the scope of this rule using one or more filters**. Then, add a prefix filter, tags, or object size.
 - To apply the rule to all objects in the bucket, choose **Apply to all objects in the bucket**.
7. Under **Lifecycle rule actions**, choose one of the following options:
 - **Expire current versions of objects** – For versioning-enabled buckets, S3 on Outposts adds a delete marker and retains the objects as noncurrent versions. For buckets that don't use S3 Versioning, S3 on Outposts permanently deletes the objects.
 - **Permanently delete noncurrent versions of objects** – S3 on Outposts permanently deletes noncurrent versions of objects.
 - **Delete expired object delete markers or incomplete multipart uploads** – S3 on Outposts permanently deletes expired object delete markers or incomplete multipart uploads.

If you limit the scope of your Lifecycle rule by using object tags, you can't choose **Delete expired object delete markers**. You also can't choose **Delete expired object delete markers** if you choose **Expire current object versions**.

 **Note**

Size-based filters can't be used with delete markers and incomplete multipart uploads.

8. If you chose **Expire current versions of objects** or **Permanently delete noncurrent versions of objects**, configure the rule trigger based on a specific date or the object age.
9. If you chose **Delete expired object delete markers**, to confirm that you want to delete expired object delete markers, select **Delete expired object delete markers**.
10. Choose **Save**.

Deleting a lifecycle rule

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the Outposts bucket that you want to delete a lifecycle rule for.
4. Choose the **Management** tab, and then under **Lifecycle rule**, choose the rule that you want to delete.
5. Choose **Delete**.

Creating and managing a lifecycle configuration by using the AWS CLI and SDK for Java

You can use S3 Lifecycle to optimize storage capacity for Amazon S3 on Outposts. You can create lifecycle rules to expire objects as they age or are replaced by newer versions. You can create, enable, disable, or delete a lifecycle rule.

For more information about S3 Lifecycle, see [Managing your storage lifecycle](#).

Note

The AWS account that creates the bucket owns it and is the only one that can create, enable, disable, or delete a lifecycle rule.

To create and manage a lifecycle configuration for an S3 on Outposts bucket by using the AWS Command Line Interface (AWS CLI) and the AWS SDK for Java, see the following examples.

Topics

- [PUT a lifecycle configuration](#)
- [GET the lifecycle configuration on an S3 on Outposts bucket](#)

PUT a lifecycle configuration

AWS CLI

The following AWS CLI example puts a lifecycle configuration policy on an Outposts bucket. This policy specifies that all objects that have the flagged prefix (*myprefix*) and tags expire

after 10 days. To use this example, replace each *user input placeholder* with your own information.

1. Save the lifecycle configuration policy to a JSON file. In this example, the file is named `lifecycle1.json`.

```
{  
    "Rules": [  
        {  
            "ID": "id-1",  
            "Filter": {  
                "And": {  
                    "Prefix": "myprefix",  
                    "Tags": [  
                        {  
                            "Value": "mytagvalue1",  
                            "Key": "mytagkey1"  
                        },  
                        {  
                            "Value": "mytagvalue2",  
                            "Key": "mytagkey2"  
                        }  
                    ],  
                    "ObjectSizeGreaterThan": 1000,  
                    "ObjectSizeLessThan": 5000  
                }  
            },  
            "Status": "Enabled",  
            "Expiration": {  
                "Days": 10  
            }  
        }  
    ]  
}
```

2. Submit the JSON file as part of the `put-bucket-lifecycle-configuration` CLI command. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [put-bucket-lifecycle-configuration](#) in the *AWS CLI Reference*.

```
aws s3control put-bucket-lifecycle-configuration --account-id 123456789012 --  
bucket arn:aws:s3-outposts:region:123456789012:outpost/op-01ac5d28a6a232904/  
bucket/example-outposts-bucket --lifecycle-configuration file://lifecycle1.json
```

SDK for Java

The following SDK for Java example puts a lifecycle configuration on an Outposts bucket. This lifecycle configuration specifies that all objects that have the flagged prefix (*myprefix*) and tags expire after 10 days. To use this example, replace each *user input placeholder* with your own information. For more information, see [PutBucketLifecycleConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

```
import com.amazonaws.services.s3control.model.*;  
  
public void putBucketLifecycleConfiguration(String bucketArn) {  
  
    S3Tag tag1 = new S3Tag().withKey("mytagkey1").withValue("mytagkey1");  
    S3Tag tag2 = new S3Tag().withKey("mytagkey2").withValue("mytagkey2");  
  
    LifecycleRuleFilter lifecycleRuleFilter = new LifecycleRuleFilter()  
        .withAnd(new LifecycleRuleAndOperator()  
            .withPrefix("myprefix")  
            .withTags(tag1, tag2))  
        .withObjectSizeGreaterThan(1000)  
        .withObjectSizeLessThan(5000);  
  
    LifecycleExpiration lifecycleExpiration = new LifecycleExpiration()  
        .withExpiredObjectDeleteMarker(false)  
        .withDays(10);  
  
    LifecycleRule lifecycleRule = new LifecycleRule()  
        .withStatus("Enabled")  
        .withFilter(lifecycleRuleFilter)  
        .withExpiration(lifecycleExpiration)  
        .withID("id-1");  
  
    LifecycleConfiguration lifecycleConfiguration = new LifecycleConfiguration()  
        .withRules(lifecycleRule);  
  
    PutBucketLifecycleConfigurationRequest reqPutBucketLifecycle = new  
    PutBucketLifecycleConfigurationRequest()
```

```
        .withAccountId(AccountId)
        .withBucket(bucketArn)
        .withLifecycleConfiguration(lifecycleConfiguration);

    PutBucketLifecycleConfigurationResult respPutBucketLifecycle =
s3ControlClient.putBucketLifecycleConfiguration(reqPutBucketLifecycle);
    System.out.printf("PutBucketLifecycleConfiguration Response: %s%n",
respPutBucketLifecycle.toString());

}
```

GET the lifecycle configuration on an S3 on Outposts bucket

AWS CLI

The following AWS CLI example gets a lifecycle configuration on an Outposts bucket. To use this command, replace each *user input placeholder* with your own information. For more information about this command, see [get-bucket-lifecycle-configuration](#) in the *AWS CLI Reference*.

```
aws s3control get-bucket-lifecycle-configuration --account-id 123456789012 --bucket
arn:aws:s3-outposts:<your-region>:123456789012:outpost/op-01ac5d28a6a232904/
bucket/example-outposts-bucket
```

SDK for Java

The following SDK for Java example gets a lifecycle configuration for an Outposts bucket. For more information, see [GetBucketLifecycleConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

```
import com.amazonaws.services.s3control.model.*;

public void getBucketLifecycleConfiguration(String bucketArn) {

    GetBucketLifecycleConfigurationRequest reqGetBucketLifecycle = new
GetBucketLifecycleConfigurationRequest()
        .withAccountId(AccountId)
        .withBucket(bucketArn);

    GetBucketLifecycleConfigurationResult respGetBucketLifecycle =
s3ControlClient.getBucketLifecycleConfiguration(reqGetBucketLifecycle);
```

```
System.out.printf("GetBucketLifecycleConfiguration Response: %s%n",
respGetBucketLifecycle.toString());  
}
```

Replicating objects for S3 on Outposts

With S3 Replication on AWS Outposts, you can configure Amazon S3 on Outposts to automatically replicate S3 objects across different Outposts, or between buckets on the same Outpost. You can use S3 Replication on Outposts to maintain multiple replicas of your data in the same or different Outposts, or across different accounts, to help meet data-residency needs. S3 Replication on Outposts helps power your compliant storage needs and data sharing across accounts. If you need to ensure that your replicas are identical to the source data, you can use S3 Replication on Outposts to make replicas of your objects that retain all metadata, such as the original object creation time, tags, and version IDs.

S3 Replication on Outposts also provides detailed metrics and notifications to monitor the status of object replication between buckets. You can use Amazon CloudWatch to monitor replication progress by tracking bytes pending replication, operations pending replication, and replication latency between your source and destination buckets. To quickly diagnose and correct configuration issues, you can also set up Amazon EventBridge to receive notifications about replication object failures. To learn more, see [Managing your replication](#).

Topics

- [Replication configuration](#)
- [Requirements for S3 Replication on Outposts](#)
- [What is replicated?](#)
- [What isn't replicated?](#)
- [What isn't supported by S3 Replication on Outposts?](#)
- [Setting up replication](#)
- [Managing your replication](#)

Replication configuration

S3 on Outposts stores a replication configuration as XML. In the replication configuration XML file, you specify an AWS Identity and Access Management (IAM) role and one or more rules.

```
<ReplicationConfiguration>
  <Role>IAM-role-ARN</Role>
  <Rule>
    ...
  </Rule>
  <Rule>
    ...
  </Rule>
  ...
</ReplicationConfiguration>
```

S3 on Outposts can't replicate objects without your permission. You grant S3 on Outposts permissions with the IAM role that you specify in the replication configuration. S3 on Outposts assumes that IAM role to replicate objects on your behalf. You must grant the required permissions to the IAM role before starting replication. For more information about these permissions for S3 on Outposts, see [Creating an IAM role](#).

You add one rule in a replication configuration in the following scenarios:

- You want to replicate all objects.
- You want to replicate one subset of objects. You identify the object subset by adding a filter in the rule. In the filter, you specify an object key prefix, tags, or a combination of both, to identify the subset of objects that the rule applies to.

You add multiple rules in a replication configuration if you want to replicate different subsets of objects. In each rule, you specify a filter that selects a different subset of objects. For example, you might choose to replicate objects that have either tax/ or document/ key prefixes. To do this, you add two rules, one that specifies the tax/ key prefix filter and another that specifies the document/ key prefix.

For more information about S3 on Outposts replication configuration and replication rules, see [ReplicationConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

Requirements for S3 Replication on Outposts

Replication requires the following:

- The destination Outpost CIDR range must be associated in your source Outpost subnet table. For more information, see [Prerequisites for creating replication rules](#).

- Both the source and destination buckets must have S3 Versioning enabled. For more information about versioning, see [Managing S3 Versioning for your S3 on Outposts bucket](#).
- Amazon S3 on Outposts must have permission to replicate objects from the source bucket to the destination bucket on your behalf. That means you must create a service role to delegate GET and PUT permissions to S3 on Outposts.
 1. Before creating the service role, you must have GET permission on the source bucket and PUT permission on the destination bucket.
 2. To create the service role to delegate permissions to S3 on Outposts, you must first configure permissions to allow an IAM entity (a user or role) to perform the `iam:CreateRole` and `iam:PassRole` actions. Then, you allow the IAM entity to create a service role. To make S3 on Outposts assume the service role on your behalf and delegate GET and PUT permissions to S3 on Outposts, you must assign the necessary trust and permissions policies to the role. For more information about these permissions for S3 on Outposts, see [Creating an IAM role](#). For more information about creating a service role, see [Creating a service role](#).

What is replicated?

By default, S3 on Outposts replicates the following:

- Objects created after you add a replication configuration.
- Object metadata from the source objects to the replicas. For information about how to replicate metadata from the replicas to the source objects, see [Replication status if Amazon S3 replica modification sync on Outposts is enabled](#).
- Object tags, if there are any.

How delete operations affect replication

If you delete an object from the source bucket, the following actions occur by default:

- If you make a DELETE request without specifying an object version ID, S3 on Outposts adds a delete marker. S3 on Outposts deals with the delete marker as follows:
 - S3 on Outposts does not replicate the delete marker by default.
 - However, you can add *delete marker replication* to non-tag-based rules. For more information about how to enable delete marker replication in your replication configuration, see [Using the S3 console](#).

- If you specify an object version ID to delete in a DELETE request, S3 on Outposts permanently deletes that object version in the source bucket. However, it doesn't replicate the deletion in the destination buckets. In other words, it doesn't delete the same object version from the destination buckets. This behavior protects data from malicious deletions.

What isn't replicated?

By default, S3 on Outposts doesn't replicate the following:

- Objects in the source bucket that are replicas that were created by another replication rule. For example, suppose you configure replication where bucket A is the source and bucket B is the destination. Now suppose that you add another replication configuration where bucket B is the source and bucket C is the destination. In this case, objects in bucket B that are replicas of objects in bucket A are not replicated to bucket C.
- Objects in the source bucket that have already been replicated to a different destination. For example, if you change the destination bucket in an existing replication configuration, S3 on Outposts won't replicate the objects again.
- Objects that are created with server-side encryption with customer-provided encryption keys (SSE-C).
- Updates to bucket-level subresources.

For example, if you change the lifecycle configuration or add a notification configuration to your source bucket, these changes are not applied to the destination bucket. This feature makes it possible to have different configurations on the source and destination buckets.

- Actions performed by lifecycle configuration.

For example, if you enable a lifecycle configuration only on your source bucket and configure expiration actions, S3 on Outposts creates delete markers for expired objects in the source bucket but doesn't replicate those markers to the destination buckets. If you want the same lifecycle configuration applied to both the source and destination buckets, enable the same lifecycle configuration on both. For more information about lifecycle configuration, see [Managing your storage lifecycle](#).

What isn't supported by S3 Replication on Outposts?

The following S3 Replication features are currently not supported by S3 on Outposts:

- S3 Replication Time Control (S3 RTC). S3 RTC is not supported because the object traffic in S3 Replication on Outposts travels over your on-premises network (the local gateway). For more information about local gateways, see [Working with the local gateway](#) in the *AWS Outposts User Guide*.
- S3 Replication for Batch Operations.

Setting up replication

Note

Objects that existed in your bucket before you set up a replication rule aren't replicated automatically. In other words, Amazon S3 on Outposts doesn't replicate objects retroactively. To replicate objects that were created before your replication configuration, you can use the CopyObject API operation to copy them to the same bucket. After the objects are copied, they appear as "new" objects in the bucket and the replication configuration will apply to them. For more information about copying an object, see [Copying an object in an Amazon S3 on Outposts bucket using the AWS SDK for Java](#) and [CopyObject](#) in the *Amazon Simple Storage Service API Reference*.

To enable S3 Replication on Outposts, add a replication rule to your source Outposts bucket. The replication rule tells S3 on Outposts to replicate objects as specified. In the replication rule, you must provide the following:

- **The source Outposts bucket access point** – The access point Amazon Resource Name (ARN) or access point alias of the bucket from which you want S3 on Outposts to replicate the objects. For more information about using access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).
- **The objects that you want to replicate** – You can replicate all of the objects in the source Outposts bucket or a subset. You identify a subset by providing a [key name prefix](#), one or more object tags, or both in the configuration.

For example, if you configure a replication rule to replicate only objects with the key name prefix Tax/, S3 on Outposts replicates objects with keys such as Tax/doc1 or Tax/doc2. But it doesn't replicate objects with the key Legal1/doc3. If you specify both a prefix and one or more tags, S3 on Outposts replicates only objects that have the specific key prefix and tags.

- **The destination Outposts bucket** – The ARN or access point alias of the bucket to which you want S3 on Outposts to replicate the objects.

You can configure the replication rule by using the REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or Amazon S3 console.

S3 on Outposts also provides API operations to support setting up replication rules. For more information, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PutBucketReplication](#)
- [GetBucketReplication](#)
- [DeleteBucketReplication](#)

Topics

Prerequisites for creating replication rules

Topics

- [Connecting your source and destination Outpost subnets](#)
- [Creating an IAM role](#)

Connecting your source and destination Outpost subnets

To have your replication traffic go from your source Outpost to your destination Outpost over your local gateway, you must add a new route to set up networking. You must connect the Classless Inter-Domain Routing (CIDR) networking ranges of your access points together. For each pair of access points, you need to set up this connection only once.

Some steps to set up the connection are different, depending on the access type of your Outposts endpoints that are associated with your access points. The access type for endpoints is either **Private** (direct virtual private cloud [VPC] routing for AWS Outposts) or **Customer owned IP** (a customer-owned IP address pool [CoIP pool] within your on-premises network).

Step 1: Find the CIDR range of your source Outposts endpoint

To find the CIDR range of your source endpoint that's associated with your source access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. In the **Outposts buckets** list, choose the source bucket that you want for replication.
4. Choose the **Outposts access points** tab, and choose the Outposts access point for the source bucket for your replication rule.
5. Choose the Outposts endpoint.
6. Copy the subnet ID for use in [Step 5](#).
7. The method that you use to find the CIDR range of the source Outposts endpoint depends on the access type of your endpoint.

In the **Outposts endpoint overview** section, see the **Access Type**.

- If the access type is **Private**, copy the **Classless inter-domain routing (CIDR)** value to use in [Step 6](#).
- If the access type is **Customer Owned IP**, do the following:
 1. Copy the **Customer owned IPv4 pool** value to use as the ID of the address pool later on.
 2. Open the AWS Outposts console at <https://console.aws.amazon.com/outposts/>.
 3. In the navigation pane, choose **Local gateway route tables**.
 4. Choose the **Local gateway route table ID** value of your source Outpost.
 5. In the details pane, choose the **CoIP pools** tab. Paste the value of your CoIP pool ID that you copied previously in the search box.
 6. For the matched CoIP pool, copy the corresponding **CIDRs** value of your source Outposts endpoint for use in [Step 6](#).

Step 2: Find the subnet ID and the CIDR range of your destination Outposts endpoint

To find the subnet ID and the CIDR range of your destination endpoint that's associated with your destination access point, follow the same substeps in [Step 1](#) and change your source Outposts endpoint to your destination Outposts endpoint when you apply those substeps. Copy the subnet

ID value of your destination Outposts endpoint for use in [Step 6](#). Copy the CIDR value of your destination Outposts endpoint for use in [Step 5](#).

Step 3: Find the local gateway ID of your source Outpost

To find the local gateway ID of your source Outpost

1. Open the AWS Outposts console at <https://console.aws.amazon.com/outposts/>.
2. In the left navigation pane, choose **Local gateways**.
3. On the **Local gateways** page, find the Outpost ID of your source Outpost that you want to use for replication.
4. Copy the local gateway ID value of your source Outpost for use in [Step 5](#).

For more information about local gateway, see [Local gateway](#) in the *AWS Outposts User Guide*.

Step 4: Find the local gateway ID of your destination Outpost

To find the local gateway ID of your destination Outpost, follow the same substeps in [Step 3](#), except look for the Outpost ID for your destination Outpost. Copy the local gateway ID value of your destination Outpost for use in [Step 6](#).

Step 5: Set up the connection from your source Outpost subnet to your destination Outpost subnet

To connect from your source Outpost subnet to your destination Outpost subnet

1. Sign in to the AWS Management Console and open the VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Subnets**.
3. In the search box, enter the subnet ID for your source Outposts endpoint that you found in [Step 1](#). Choose the subnet with the matched subnet ID.
4. For the matched subnet item, choose the **Route table** value of this subnet.
5. On the page with a selected route table, choose **Actions**, and then choose **Edit routes**.
6. On the **Edit routes** page, choose **Add route**.
7. Under **Destination**, enter the CIDR range of your destination Outposts endpoint that you found in [Step 2](#).

8. Under **Target**, choose **Outpost Local Gateway**, and enter the local gateway ID of your source Outpost that you found in [Step 3](#).
9. Choose **Save changes**.
10. Make sure the **Status** for the route is **Active**.

Step 6: Set up the connection from your destination Outpost subnet to your source Outpost subnet

1. Sign in to the AWS Management Console and open the VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Subnets**.
3. In the search box, enter the subnet ID for your destination Outposts endpoint that you found in [Step 2](#). Choose the subnet with the matched subnet ID.
4. For the matched subnet item, choose the **Route table** value of this subnet.
5. On the page with a selected route table, choose **Actions**, and then choose **Edit routes**.
6. On the **Edit routes** page, choose **Add route**.
7. Under **Destination**, enter the CIDR range of your source Outposts endpoint that you found in [Step 1](#).
8. Under **Target**, choose **Outpost Local Gateway**, and enter the local gateway ID of your destination Outpost that you found in [Step 4](#).
9. Choose **Save changes**.
10. Make sure the **Status** for the route is **Active**.

After you connect the CIDR networking ranges of your source and destination access points, you must create an AWS Identity and Access Management (IAM) role.

Creating an IAM role

By default, all S3 on Outposts resources—buckets, objects, and related subresources—are private, and only the resource owner can access the resource. S3 on Outposts needs permissions to read and replicate objects from the source Outposts bucket. You grant these permissions by creating an IAM *service role* and specifying that role in your replication configuration.

This section explains the trust policy and minimum required permissions policy. The example walkthroughs provide step-by-step instructions to create an IAM role. For more information, see

[Creating replication rules on Outposts](#). For more information about IAM roles, see [IAM roles](#) in the [IAM User Guide](#).

- The following example shows a *trust policy*, where you identify S3 on Outposts as the service principal that can assume the role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3-outposts.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- The following example shows an *access policy*, where you grant the role permissions to perform replication tasks on your behalf. When S3 on Outposts assumes the role, it has the permissions that you specify in this policy. To use this policy, replace the *user input placeholders* with your own information. Make sure to replace them with the Outpost IDs of your source and destination Outposts and the bucket names and access point names of your source and destination Outposts buckets.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3-outposts:GetObjectVersionForReplication",  
                "s3-outposts:GetObjectVersionTagging"  
            ],  
            "Resource": [  
                "arn:aws:s3-outposts:region:123456789012:outpost/SOURCE-OUTPOST-ID/  
                bucket/SOURCE-OUTPOSTS-BUCKET/object/*",  
                "arn:aws:s3-outposts:region:123456789012:outpost/SOURCE-OUTPOST-ID/  
                accesspoint/SOURCE-OUTPOSTS-BUCKET-ACCESS-POINT/object/*"  
            ]  
        },  
    ]  
}
```

```
{  
    "Effect": "Allow",  
    "Action": [  
        "s3-outposts:ReplicateObject",  
        "s3-outposts:ReplicateDelete"  
    ],  
    "Resource": [  
        "arn:aws:s3-outposts:region:123456789012:outpost/DESTINATION-OUTPOST-ID/  
        bucket/DESTINATION-OUTPOSTS-BUCKET/object/*",  
        "arn:aws:s3-outposts:region:123456789012:outpost/DESTINATION-OUTPOST-ID/  
        accesspoint/DESTINATION-OUTPOSTS-BUCKET-ACCESS-POINT/object/*"  
    ]  
}
```

The access policy grants permissions for the following actions:

- `s3-outposts:GetObjectVersionForReplication` – Permission for this action is granted on all objects to allow S3 on Outposts to get a specific object version that's associated with each object.
- `s3-outposts:GetObjectVersionTagging` – Permission for this action on objects in the ***SOURCE-OUTPOSTS-BUCKET*** bucket (the source bucket) allows S3 on Outposts to read object tags for replication. For more information, see [Adding tags for S3 on Outposts buckets](#). If S3 on Outposts doesn't have this permission, it replicates the objects, but not the object tags.
- `s3-outposts:ReplicateObject` and `s3-outposts:ReplicateDelete` – Permissions for these actions on all objects in the ***DESTINATION-OUTPOSTS-BUCKET*** bucket (the destination bucket) allow S3 on Outposts to replicate objects or delete markers to the destination Outposts bucket. For information about delete markers, see [How delete operations affect replication](#).

 **Note**

- Permission for the `s3-outposts:ReplicateObject` action on the ***DESTINATION-OUTPOSTS-BUCKET*** bucket (the destination bucket) also allows replication of object tags. Therefore, you don't need to explicitly grant permission for the `s3-outposts:ReplicateTags` action.
- For cross-account replication, the owner of the destination Outposts bucket must update its bucket policy to grant permission for the `s3-`

`outposts:ReplicateObject` action on the `DESTINATION-OUTPOSTS-BUCKET`.

The `s3-outposts:ReplicateObject` action allows S3 on Outposts to replicate objects and object tags to the destination Outposts bucket.

For a list of S3 on Outposts actions, see [Actions defined by S3 on Outposts](#).

⚠ Important

The AWS account that owns the IAM role must have permissions for the actions that it grants to the IAM role.

For example, suppose that the source Outposts bucket contains objects owned by another AWS account. The owner of the objects must explicitly grant the AWS account that owns the IAM role the required permissions through the bucket policy and the access point policy. Otherwise, S3 on Outposts can't access the objects, and replication of the objects fails.

The permissions described here are related to the minimum replication configuration. If you choose to add optional replication configurations, you must grant additional permissions to S3 on Outposts.

Granting permissions when the source and destination Outposts buckets are owned by different AWS accounts

When the source and destination Outposts buckets aren't owned by the same accounts, the owner of the destination Outposts bucket must update the bucket and access point policies for the destination bucket. These policies must grant the owner of the source Outposts bucket and the IAM service role permissions to perform replication actions, as shown in the following policy examples, or replication will fail. In these policy examples, `DESTINATION-OUTPOSTS-BUCKET` is the destination bucket. To use these policy examples, replace the `user input placeholders` with your own information.

If you're creating the IAM service role manually, set the role path as `role/service-role/`, as shown in the following policy examples. For more information, see [IAM ARNs](#) in the *IAM User Guide*.

```
{  
    "Version": "2012-10-17",  
    "Id": "PolicyForDestinationBucket",  
    "Statement": [
```

```
{  
    "Sid": "Permissions on objects",  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": "arn:aws:iam::SourceBucket-account-ID:role/service-role/source-  
account-IAM-role"  
    },  
    "Action": [  
        "s3-outposts:ReplicateDelete",  
        "s3-outposts:ReplicateObject"  
    ],  
    "Resource": [  
        "arn:aws:s3-outposts:region:DestinationBucket-account-  
ID:outpost/DESTINATION-OUTPOST-ID/bucket/DESTINATION-OUTPOSTS-BUCKET/object/*"  
    ]  
}  
]  
}
```

```
{  
    "Version": "2012-10-17",  
    "Id": "PolicyForDestinationAccessPoint",  
    "Statement": [  
        {  
            "Sid": "Permissions on objects",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::SourceBucket-account-ID:role/service-role/source-  
account-IAM-role"  
            },  
            "Action": [  
                "s3-outposts:ReplicateDelete",  
                "s3-outposts:ReplicateObject"  
            ],  
            "Resource" : [  
                "arn:aws:s3-outposts:region:DestinationBucket-account-  
ID:outpost/DESTINATION-OUTPOST-ID/accesspoint/DESTINATION-OUTPOSTS-BUCKET-ACCESS-POINT/  
object/*"  
            ]  
        }  
    ]  
}
```

Note

If objects in the source Outposts bucket are tagged, note the following:

If the source Outposts bucket owner grants S3 on Outposts permission for the s3-outposts:GetObjectVersionTagging and s3-outposts:ReplicateTags actions to replicate object tags (through the IAM role), Amazon S3 replicates the tags along with the objects. For information about the IAM role, see [Creating an IAM role](#).

Creating replication rules on Outposts

S3 Replication on Outposts is the automatic, asynchronous replication of objects across buckets in the same or different AWS Outposts. Replication copies newly created objects and object updates from a source Outposts bucket to a destination Outposts bucket or buckets. For more information, see [Replicating objects for S3 on Outposts](#).

Note

Objects that existed in the source Outposts bucket before you set up replication rules aren't replicated. In other words, S3 on Outposts doesn't replicate objects retroactively. To replicate objects that were created before your replication configuration, you can use the CopyObject API operation to copy them to the same bucket. After the objects are copied, they appear as "new" objects in the bucket and the replication configuration will apply to them. For more information about copying an object, see [Copying an object in an Amazon S3 on Outposts bucket using the AWS SDK for Java](#) and [CopyObject](#) in the *Amazon Simple Storage Service API Reference*.

When you configure replication, you add replication rules to the source Outposts bucket. Replication rules define which source Outposts bucket objects to replicate and the destination Outposts bucket or buckets where the replicated objects will be stored. You can create a rule to replicate all the objects in a bucket or a subset of objects with a specific key name prefix, one or more object tags, or both. A destination Outposts bucket can be in the same Outpost as the source Outposts bucket, or it can be in a different Outpost.

For S3 on Outposts replication rules, you must provide both the source Outposts bucket's access point Amazon Resource Name (ARN) and the destination Outposts bucket's access point ARN instead of the source and destination Outposts bucket names.

If you specify an object version ID to delete, S3 on Outposts deletes that object version in the source Outposts bucket. But it doesn't replicate the deletion to the destination Outposts bucket. In other words, it doesn't delete the same object version from the destination Outposts bucket. This behavior protects data from malicious deletions.

When you add a replication rule to an Outposts bucket, the rule is enabled by default, so the rule starts working as soon as you save it.

In this example, you set up replication for source and destination Outposts buckets that are on different Outposts and are owned by the same AWS account. Examples are provided for using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), and the AWS SDK for Java and AWS SDK for .NET. For information about cross-account S3 Replication on Outposts permissions, see [Granting permissions when the source and destination Outposts buckets are owned by different AWS accounts](#).

For prerequisites to set up S3 on Outposts replication rules, see [Prerequisites for creating replication rules](#).

Using the S3 console

Follow these steps to configure a replication rule when the destination Amazon S3 on Outposts bucket is in a different Outpost from the source Outposts bucket.

If the destination Outposts bucket is in a different account from the source Outposts bucket, you must add a bucket policy to the destination Outposts bucket to grant the owner of the source Outposts bucket account permission to replicate objects in the destination Outposts bucket. For more information, see [Granting permissions when the source and destination buckets are owned by different AWS accounts](#).

To create a replication rule

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Outposts Buckets** list, choose the name of the bucket that you want to use as the source bucket.
3. Choose the **Management** tab, scroll down to the **Replication rules** section, and then choose **Create replication rule**.
4. For **Replication rule name**, enter a name for your rule to help identify the rule later. The name is required and must be unique within the bucket.

5. Under **Status**, **Enabled** is chosen by default. An enabled rule starts to work as soon as you save it. If you want to enable the rule later, choose **Disabled**.
6. Under **Priority**, the rule's priority value determines which rule to apply if there are overlapping rules. When objects are included in the scope of more than one replication rule, S3 on Outposts uses these priority values to avoid conflicts. By default, new rules are added to the replication configuration at the highest priority. The higher the number, the higher the priority.

To change the priority for the rule, after you save the rule, choose the rule name from the replication rule list, choose **Actions**, and then choose **Edit priority**.

7. Under **Source bucket**, you have the following options for setting the replication source:
 - To replicate the whole bucket, choose **Apply to all objects in the bucket**.
 - To apply prefix or tag filtering to the replication source, choose **Limit the scope of this rule by using one or more filters**. You can combine a prefix and tags.
 - To replicate all objects that have the same prefix, under **Prefix**, enter a prefix in the box. Using the **Prefix** filter limits replication to all objects that have names that begin with the same string (for example, pictures).

If you enter a prefix that is the name of a folder, you must use a / (forward slash) as the last character (for example, pictures/).

- To replicate all objects that have one or more of the same object tags, choose **Add tag**, and then enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see [Adding tags for S3 on Outposts buckets](#).

8. To access your S3 on Outposts source bucket for replication, under **Source access point name**, choose an access point that is attached to the source bucket.
9. Under **Destination**, choose the access point ARN of the destination Outposts bucket where you want S3 on Outposts to replicate objects. The destination Outposts bucket can be in the same or a different AWS account as the source Outposts bucket.

If the destination bucket is in a different account from the source Outposts bucket, you must add a bucket policy to the destination Outposts bucket to grant the owner of the source Outposts bucket account permission to replicate objects to the destination Outposts bucket. For more information, see [Granting permissions when the source and destination Outposts buckets are owned by different AWS accounts](#).

Note

If versioning is not enabled on the destination Outposts bucket, you get a warning that contains an **Enable versioning** button. Choose this button to enable versioning on the bucket.

10. Set up an AWS Identity and Access Management (IAM) service role that S3 on Outposts can assume to replicate objects on your behalf.

To set up an IAM role, under **IAM role**, do one of the following:

- To have S3 on Outposts create a new IAM role for your replication configuration, choose **Choose from existing IAM roles**, and then choose **Create new role**. When you save the rule, a new policy is generated for the IAM role that matches the source and destination Outposts buckets that you choose. We recommend that you choose **Create new role**.
- You can also choose to use an existing IAM role. If you do, you must choose a role that grants S3 on Outposts the necessary permissions for replication. If this role doesn't grant S3 on Outposts sufficient permissions to follow your replication rule, replication fails.

To choose an existing role, choose **Choose from existing IAM roles**, and then choose the role from the dropdown menu. You can also choose **Enter an IAM role ARN** and then enter the IAM role's Amazon Resource Name (ARN).

Important

When you add a replication rule to an S3 on Outposts bucket, you must have the `iam:CreateRole` and `iam:PassRole` permissions to be able to create and pass the IAM role that grants S3 on Outposts replication permissions. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

11. All objects in Outposts buckets are encrypted by default. For more information about S3 on Outposts encryption, see [Data encryption in S3 on Outposts](#). Only objects that are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3) can be replicated. The replication of objects that are encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) or server-side encryption with customer-provided encryption keys (SSE-C) is not supported.

12. As needed, enable the following additional options while setting the replication rule configuration:
 - If you want to enable S3 on Outposts replication metrics in your replication configuration, select **Replication metrics**. For more information, see [Monitoring progress with replication metrics](#).
 - If you want to enable delete marker replication in your replication configuration, select **Delete marker replication**. For more information, see [How delete operations affect replication](#).
 - If you want to replicate metadata changes made to the replicas back to the source objects, select **Replica modification sync**. For more information, see [Replication status if Amazon S3 replica modification sync on Outposts is enabled](#).
13. To finish, choose **Create rule**.

After you save your rule, you can edit, enable, disable, or delete your rule. To do so, go to the **Management** tab for the source Outposts bucket, scroll down to the **Replication rules** section, choose your rule, and then choose **Edit rule**.

Using the AWS CLI

To use the AWS CLI to set up replication when the source and destination Outposts buckets are owned by the same AWS account, you do the following:

- Create source and destination Outposts buckets.
- Enable versioning on both of the buckets.
- Create an IAM role that gives S3 on Outposts permission to replicate objects.
- Add the replication configuration to the source Outposts bucket.

To verify your setup, you test it.

To set up replication when the source and destination Outposts buckets are owned by the same AWS account

1. Set a credentials profile for the AWS CLI. In this example, we use the profile name acctA. For information about setting credential profiles, see [Named profiles](#) in the *AWS Command Line Interface User Guide*.

⚠ Important

The profile that you use for this exercise must have the necessary permissions. For example, in the replication configuration, you specify the IAM service role that S3 on Outposts can assume. You can do this only if the profile that you use has the `iam:CreateRole` and `iam:PassRole` permissions. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

If you use administrator credentials to create a named profile, the named profile will have the necessary permission to perform all the tasks.

2. Create a source bucket and enable versioning on it. The following `create-bucket` command creates a `SOURCE-OUTPOSTS-BUCKET` bucket in the US East (N. Virginia) (`us-east-1`) Region. To use this command, replace the *user input placeholders* with your own information.

```
aws s3control create-bucket --bucket SOURCE-OUTPOSTS-BUCKET --outpost-id SOURCE-OUTPOST-ID --profile acctA --region us-east-1
```

The following `put-bucket-versioning` command enables versioning on the `SOURCE-OUTPOSTS-BUCKET` bucket. To use this command, replace the *user input placeholders* with your own information.

```
aws s3control put-bucket-versioning --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/SOURCE-OUTPOST-ID/bucket/SOURCE-OUTPOSTS-BUCKET --versioning-configuration Status=Enabled --profile acctA
```

3. Create a destination bucket and enable versioning on it. The following `create-bucket` command creates a `DESTINATION-OUTPOSTS-BUCKET` bucket in the US West (Oregon) (`us-west-2`) Region. To use this command, replace the *user input placeholders* with your own information.

ⓘ Note

To set up a replication configuration when both the source and destination Outposts buckets are in the same AWS account, you use the same named profile. This example uses `acctA`. To test the replication configuration when the buckets are owned by different AWS accounts, you specify different profiles for each bucket.

```
aws s3control create-bucket --bucket DESTINATION-OUTPOSTS-BUCKET --create-bucket-configuration LocationConstraint=us-west-2 --outpost-id DESTINATION-OUTPOST-ID --profile acctA --region us-west-2
```

The following put-bucket-versioning command enables versioning on the **DESTINATION-OUTPOSTS-BUCKET** bucket. To use this command, replace the *user input placeholders* with your own information.

```
aws s3control put-bucket-versioning --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/DESTINATION-OUTPOST-ID/bucket/DESTINATION-OUTPOSTS-BUCKET --versioning-configuration Status=Enabled --profile acctA
```

4. Create an IAM service role. Later in the replication configuration, you add this service role to the **SOURCE-OUTPOSTS-BUCKET** bucket. S3 on Outposts assumes this role to replicate objects on your behalf. You create an IAM role in two steps:
 - a. Create an IAM role.
 - i. Copy the following trust policy and save it to a file named `s3-on-outposts-role-trust-policy.json` in the current directory on your local computer. This policy grants S3 on Outposts service principal permissions to assume the service role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3-outposts.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- ii. Run the following command to create the role. Replace the *user input placeholders* with your own information.

```
aws iam create-role --role-name replicationRole --assume-role-policy-document file://s3-on-outposts-role-trust-policy.json --profile acctA
```

b. Attach a permissions policy to the service role.

- i. Copy the following permissions policy and save it to a file named s3-on-outposts-role-permissions-policy.json in the current directory on your local computer. This policy grants permissions for various S3 on Outposts bucket and object actions. To use this policy, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3-outposts:GetObjectVersionForReplication",  
                "s3-outposts:GetObjectVersionTagging"  
            ],  
            "Resource": [  
                "arn:aws:s3-outposts:region:123456789012:outpost/SOURCE-OUTPOST-ID/bucket/SOURCE-OUTPOSTS-BUCKET/object/*",  
                "arn:aws:s3-outposts:region:123456789012:outpost/SOURCE-OUTPOST-ID/accesspoint/SOURCE-OUTPOSTS-BUCKET-ACCESS-POINT/object/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3-outposts:ReplicateObject",  
                "s3-outposts:ReplicateDelete"  
            ],  
            "Resource": [  
                "arn:aws:s3-outposts:region:123456789012:outpost/DESTINATION-OUTPOST-ID/bucket/DESTINATION-OUTPOSTS-BUCKET/object/*",  
                "arn:aws:s3-outposts:region:123456789012:outpost/DESTINATION-OUTPOST-ID/accesspoint/DESTINATION-OUTPOSTS-BUCKET-ACCESS-POINT/object/*"  
            ]  
        }  
    ]  
}
```

```
}
```

- ii. Run the following command to create a policy and attach it to the role. Replace the *user input placeholders* with your own information.

```
aws iam put-role-policy --role-name replicationRole --policy-document file://s3-on-outposts-role-permissions-policy.json --policy-name replicationRolePolicy --profile acctA
```

5. Add a replication configuration to the *SOURCE-OUTPOSTS-BUCKET* bucket.

- a. Although the S3 on Outposts API requires a replication configuration in XML format, the AWS CLI requires that you specify the replication configuration in JSON format. Save the following JSON in a file called `replication.json` to the local directory on your computer. To use this configuration, replace the *user input placeholders* with your own information.

```
{
  "Role": "IAM-role-ARN",
  "Rules": [
    {
      "Status": "Enabled",
      "Priority": 1,
      "DeleteMarkerReplication": { "Status": "Disabled" },
      "Filter" : { "Prefix": "Tax" },
      "Destination": {
        "Bucket":
          "arn:aws:s3-outposts:region:123456789012:outpost/DESTINATION-OUTPOST-ID/accesspoint/DESTINATION-OUTPOSTS-BUCKET-ACCESS-POINT"
      }
    }
  ]
}
```

- b. Run the following `put-bucket-replication` command to add the replication configuration to your source Outposts bucket. To use this command, replace the *user input placeholders* with your own information.

```
aws s3control put-bucket-replication --account-id 123456789012 --
bucket arn:aws:s3-outposts:region:123456789012:outpost/SOURCE-OUTPOST-
```

```
ID/bucket/SOURCE-OUTPOSTS-BUCKET --replication-configuration file://replication.json --profile acctA
```

- c. To retrieve the replication configuration, use the get-bucket-replication command. To use this command, replace the *user input placeholders* with your own information.

```
aws s3control get-bucket-replication --account-id 123456789012 --bucket arn:aws:s3-outposts:region:123456789012:outpost/SOURCE-OUTPOST-ID/bucket/SOURCE-OUTPOSTS-BUCKET --profile acctA
```

6. Test the setup in the Amazon S3 console:

- Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- In the *SOURCE-OUTPOSTS-BUCKET* bucket, create a folder named Tax.
- Add sample objects to the Tax folder in the *SOURCE-OUTPOSTS-BUCKET* bucket.
- In the *DESTINATION-OUTPOSTS-BUCKET* bucket, verify the following:
 - S3 on Outposts replicated the objects.

Note

The amount of time that it takes for S3 on Outposts to replicate an object depends on the size of the object. For information about how to see the status of replication, see [Getting replication status information](#).

- On the object's **Properties** tab, the **Replication status** is set to **Replica** (identifying this as a replica object).

Managing your replication

This section describes additional replication configuration options that are available in S3 on Outposts, how to determine the replication status, and how to troubleshoot replication. For information about core replication configuration, see [Setting up replication](#).

Topics

- [Monitoring progress with replication metrics](#)

- [Getting replication status information](#)
- [Troubleshooting replication](#)
- [Using EventBridge for S3 Replication on Outposts](#)

Monitoring progress with replication metrics

S3 Replication on Outposts provides detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor in 5-minute intervals the progress of replication by tracking bytes pending replication, replication latency replication, and operations pending. To assist in troubleshooting any configuration issues, you can also set up Amazon EventBridge to receive notifications about replication failures.

When replication metrics are enabled, S3 Replication on Outposts publishes the following metrics to Amazon CloudWatch:

- **Bytes Pending Replication** – The total number of bytes of objects that are pending replication for a given replication rule.
- **Replication Latency** – The maximum number of seconds by which the replication destination bucket is behind the source bucket for a given replication rule.
- **Operations Pending Replication** – The number of operations that are pending replication for a given replication rule. Operations include objects, delete markers, and tags.

Note

S3 Replication on Outposts metrics are billed at the same rate as CloudWatch custom metrics. For more information, see [CloudWatch pricing](#).

Getting replication status information

The replication status can help you determine the current state of an object that's being replicated by Amazon S3 on Outposts. The replication status of a source object will return either PENDING, COMPLETED, or FAILED. The replication status of a replica will return REPLICA.

Replication status overview

In a replication scenario, you have a source bucket on which you configure replication and a destination bucket to which S3 on Outposts replicates objects. When you request an object (using

GetObject) or object metadata (using HeadObject) from these buckets, S3 on Outposts returns the x-amz-replication-status header in the response as follows:

- When you request an object from the source bucket, S3 on Outposts returns the x-amz-replication-status header if the object in your request is eligible for replication.

For example, suppose that you specify the object prefix TaxDocs in your replication configuration to tell S3 on Outposts to replicate only objects with the key name prefix TaxDocs. Any objects that you upload that have this key name prefix—for example, TaxDocs/document1.pdf—will be replicated. For object requests with this key name prefix, S3 on Outposts returns the x-amz-replication-status header with one of the following values for the object's replication status: PENDING, COMPLETED, or FAILED.

 **Note**

If object replication fails after you upload an object, you can't retry replication. You must upload the object again. Objects transition to a FAILED state for issues such as missing replication role permissions or missing bucket permissions. For temporary failures, such as if a bucket or your Outpost is unavailable, the replication status doesn't transition to FAILED, but remains PENDING. After the resource is back online, S3 on Outposts resumes replicating those objects.

- When you request an object from a destination bucket, if the object in your request is a replica that S3 on Outposts created, S3 on Outposts returns the x-amz-replication-status header with the value REPLICA.

 **Note**

Before deleting an object from a source bucket that has replication enabled, check the object's replication status to ensure that the object has been replicated.

Replication status if Amazon S3 replica modification sync on Outposts is enabled

When your replication rules enable S3 on Outposts replica modification sync, replicas can report statuses other than REPLICA. If metadata changes are in the process of replicating, the x-amz-replication-status header for the replica returns PENDING. If replica modification sync fails to

replicate metadata, the header for the replica returns FAILED. If metadata is replicated correctly, the header for the replica returns the value REPLICA.

Troubleshooting replication

If object replicas don't appear in the destination Amazon S3 on Outposts bucket after you configure replication, use these troubleshooting tips to identify and fix issues.

- The time it takes S3 on Outposts to replicate an object depends on several factors, including the distance between the source and destination Outposts, and the size of the object.

You can check the source object's replication status. If the object's replication status is PENDING, S3 on Outposts hasn't completed the replication. If the object's replication status is FAILED, check the replication configuration that you set on the source bucket.

- In the replication configuration on the source bucket, verify the following:
 - The access point Amazon Resource Name (ARN) of the destination bucket is correct.
 - The key name prefix is correct. For example, if you set the configuration to replicate objects with the prefix Tax, then only objects with key names such as Tax/document1 or Tax/document2 are replicated. An object with the key name document3 is not replicated.
 - The status is Enabled.
- Verify that versioning hasn't been suspended on either bucket. Both the source and destination buckets must have versioning enabled.
- If the destination bucket is owned by another AWS account, verify that the bucket owner has a bucket policy on the destination bucket that allows the source bucket owner to replicate objects. For an example, see [Granting permissions when the source and destination Outposts buckets are owned by different AWS accounts](#).
- If an object replica doesn't appear in the destination bucket, the following issues might prevent replication:
 - S3 on Outposts doesn't replicate an object in a source bucket that is a replica created by another replication configuration. For example, if you set a replication configuration from bucket A to bucket B to bucket C, S3 on Outposts doesn't replicate object replicas in bucket B to bucket C.

If you want to replicate objects in bucket A to bucket B and bucket C, set multiple bucket destinations in different replication rules for your source bucket replication configuration. For example, create two replication rules on source bucket A, with one rule to replicate to destination bucket B and the other rule to replicate to destination bucket C.

- A source bucket owner can grant other AWS accounts permission to upload objects. By default, the source bucket owner doesn't have permissions for the objects created by other accounts. The replication configuration replicates only the objects for which the source bucket owner has access permissions. To avoid replication issues, the source bucket owner can grant other AWS accounts permissions to create objects conditionally, requiring explicit access permissions on those objects. For an example policy, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control.](#)
- Suppose that in the replication configuration, you add a rule to replicate a subset of objects that have a specific tag. In this case, you must assign the specific tag key and value at the time that the object is created in order for S3 on Outposts to replicate the object. If you first create an object and then add the tag to that existing object, S3 on Outposts doesn't replicate the object.
- Replication fails if the bucket policy denies access to the replication role for any of the following actions:

Source bucket:

```
"s3-outposts:GetObjectVersionForReplication",
"s3-outposts:GetObjectVersionTagging"
```

Destination buckets:

```
"s3-outposts:ReplicateObject",
"s3-outposts:ReplicateDelete",
"s3-outposts:ReplicateTags"
```

- Amazon EventBridge can notify you when objects don't replicate to their destination Outposts. For more information, see [Using EventBridge for S3 Replication on Outposts](#).

Using EventBridge for S3 Replication on Outposts

Amazon S3 on Outposts is integrated with Amazon EventBridge and uses the s3-outposts namespace. EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. For more information, see [What is Amazon EventBridge?](#) in the *Amazon EventBridge User Guide*.

To assist in troubleshooting any replication configuration issues, you can set up Amazon EventBridge to receive notifications about replication failure events. EventBridge can notify you in

instances when objects don't replicate to their destination Outposts. For more information about the current state of an object that's being replicated, see [Replication status overview](#).

Whenever certain events happen in your Outposts bucket, S3 on Outposts can send events to EventBridge. Unlike other destinations, you don't need to select which event types that you want to deliver. You can also use EventBridge rules to route events to additional targets. After EventBridge is enabled, S3 on Outposts sends all of the following events to EventBridge.

Event type	Description	Namespace
OperationFailedReplication	The replication of an object within a replication rule failed. For more information about S3 Replication on Outposts failure reasons, see Using EventBridge to view S3 Replication on Outposts failure reasons .	s3-outposts

Using EventBridge to view S3 Replication on Outposts failure reasons

The following table lists S3 Replication on Outposts failure reasons. You can configure an EventBridge rule to publish and view the failure reason through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), AWS Lambda, or Amazon CloudWatch Logs. For more information about the permissions that are required to use these resources for EventBridge, see [Using resource-based policies for EventBridge](#).

Replication failure reason	Description
AssumeRoleNotPermitted	S3 on Outposts can't assume the AWS Identity and Access Management (IAM) role that's specified in the replication configuration.
DstBucketNotFound	S3 on Outposts can't find the destination bucket that's specified in the replication configuration.
DstBucketUnversioned	Versioning isn't enabled on the Outposts destination bucket. To replicate objects with

Replication failure reason	Description
	S3 Replication on Outposts, you must enable versioning on the destination bucket.
DstDelObjNotPermitted	S3 on Outposts can't replicate deletes to the destination bucket. The <code>s3-outposts:ReplicateDelete</code> permission might be missing for the destination bucket.
DstMultipartCompleteNotPermitted	S3 on Outposts can't complete a multipart upload of objects in the destination bucket. The <code>s3-outposts:ReplicateObject</code> permission might be missing for the destination bucket.
DstMultipartInitNotPermitted	S3 on Outposts can't initiate a multipart upload of objects to the destination bucket. The <code>s3-outposts:ReplicateObject</code> permission might be missing for the destination bucket.
DstMultipartPartUploadNotPermitted	S3 on Outposts can't upload multipart objects in the destination bucket. The <code>s3-outposts:ReplicateObject</code> permission might be missing for the destination bucket.
DstOutOfCapacity	S3 on Outposts can't replicate to the destination Outpost because the Outpost is out of S3 storage capacity.
DstPutObjNotPermitted	S3 on Outposts can't replicate objects to the destination bucket. The <code>s3-outposts:ReplicateObject</code> permission might be missing for the destination bucket.

Replication failure reason	Description
DstPutTaggingNotPermitted	S3 on Outposts can't replicate object tags to the destination bucket. The <code>s3-outposts:ReplicateObject</code> permission might be missing for the destination bucket.
DstVersionNotFound	S3 on Outposts can't find the required object version in the destination bucket in order to replicate that object version's metadata.
SrcBucketReplicationConfigMissing	S3 on Outposts can't find a replication configuration for the access point that's associated with the source Outposts bucket.
SrcGetObjNotPermitted	S3 on Outposts can't access the object in the source bucket for replication. The <code>s3-outposts:GetObjectVersionForReplication</code> permission might be missing for the source bucket.
SrcGetTaggingNotPermitted	S3 on Outposts can't access the object tag information from the source bucket. The <code>s3-outposts:GetObjectVersionTagging</code> permission might be missing for the source bucket.
SrcHeadObjectNotPermitted	S3 on Outposts can't retrieve object metadata from the source bucket. The <code>s3-outposts:GetObjectVersionForReplication</code> permission might be missing for the source bucket.
SrcObjectNotEligible	The object isn't eligible for replication. The object or its object tags don't match the replication configuration.

For more information about troubleshooting replication, see the following topics:

- [Creating an IAM role](#)
- [Troubleshooting replication](#)

Monitoring EventBridge with CloudWatch

For monitoring, Amazon EventBridge integrates with Amazon CloudWatch. EventBridge automatically sends metrics to CloudWatch every minute. These metrics include the number of [events](#) that have been matched by a [rule](#) and the number of times a [target](#) is invoked by a rule. When a rule runs in EventBridge, all of the targets associated with the rule are invoked. You can monitor your EventBridge behavior through CloudWatch in the following ways.

- You can monitor the available [EventBridge metrics](#) for your EventBridge rules from the CloudWatch dashboard. Then, you can use CloudWatch features, such as CloudWatch alarms, to set alarms on certain metrics. If those metrics reach the custom threshold values that you've specified in the alarms, you receive notifications and can take action accordingly.
- You can set Amazon CloudWatch Logs as a target of your EventBridge rule. Then, EventBridge creates log streams and CloudWatch Logs stores the text from the events as log entries. For more information, see [EventBridge and CloudWatch Logs](#).

For more information about debugging EventBridge event delivery and archiving events, see the following topics:

- [Event retry policy and using dead-letter queues](#)
- [Archiving EventBridge events](#)

Sharing S3 on Outposts by using AWS RAM

Amazon S3 on Outposts supports sharing S3 capacity across multiple accounts within an organization by using AWS Resource Access Manager ([AWS RAM](#)). With S3 on Outposts sharing, you can allow others to create and manage buckets, endpoints, and access points on your Outpost.

This topic demonstrates how to use AWS RAM to share S3 on Outposts and related resources with another AWS account in your AWS organization.

Prerequisites

- The Outpost owner account has an organization configured in AWS Organizations. For more information, see [Creating an organization](#) in the *AWS Organizations User Guide*.
- The organization includes the AWS account that you want to share your S3 on Outposts capacity with. For more information, see [Sending invitations to AWS accounts](#) in the *AWS Organizations User Guide*.
- Select one of the following options that you want to share. The second resource (either **Subnets** or **Outposts**) must be selected so that endpoints are also accessible. Endpoints are a networking requirement in order to access data stored in S3 on Outposts.

Option 1	Option 2
S3 on Outposts Allows the user to create buckets on your Outposts and access points and to add objects to those buckets.	S3 on Outposts Allows the user to create buckets on your Outposts and access points and to add objects to those buckets.
Subnets Allows the user to use your virtual private cloud (VPC) and the endpoints that are associated with your subnet.	Outposts Allows the user to see S3 capacity charts and the AWS Outposts console home page. Also allows users to create subnets on shared Outposts and create endpoints.

Procedure

- Sign in to the AWS Management Console by using the AWS account that owns the Outpost, and then open the AWS RAM console at <https://console.aws.amazon.com/ram>.
- Make sure that you have enabled sharing with AWS Organizations in AWS RAM. For information, see [Enable resource sharing within AWS Organizations](#) in the *AWS RAM User Guide*.
- Use either Option 1 or Option 2 in the [prerequisites](#) to create a resource share. If you have multiple S3 on Outposts resources, select the Amazon Resource Names (ARNs) of the resources that you want to share. To enable endpoints, share either your subnet or Outpost.

For more information about how to create a resource share, see [Create a resource share](#) in the *AWS RAM User Guide*.

4. The AWS account that you shared your resources with should now be able to use S3 on Outposts. Depending on the option that you selected in the [prerequisites](#), provide the following information to the account user:

Option 1	Option 2
The Outpost ID	The Outpost ID
The VPC ID	
The subnet ID	
The security group ID	

 **Note**

The user can confirm that the resources have been shared with them by using the AWS RAM console, the AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. The user can view their existing resource shares by using the [get-resource-shares](#) CLI command.

Usage examples

After you have shared your S3 on Outposts resources with another account, that account can manage buckets and objects on your Outpost. If you shared the **Subnets** resource, then that account can use the endpoint that you created. The following examples demonstrate how a user can use the AWS CLI to interact with your Outpost after you share these resources.

Example : Create a bucket

The following example creates a bucket named **DOC-EXAMPLE-BUCKET1** on the Outpost **op-01ac5d28a6a232904**. Before using this command, replace each **user input placeholder** with the appropriate values for your use case.

```
aws s3control create-bucket --bucket DOC-EXAMPLE-BUCKET1 --outpost-id op-01ac5d28a6a232904
```

For more information about this command, see [create-bucket](#) in the *AWS CLI Reference*.

Example : Create an access point

The following example creates an access point on an Outpost by using the example parameters in the following table. Before using this command, replace these *user input placeholder* values and the AWS Region code with the appropriate values for your use case.

Parameter	Value
Account ID	<i>111122223333</i>
Access point name	<i>example-outpost-access-point</i>
Outpost ID	<i>op-01ac5d28a6a232904</i>
Outpost bucket name	<i>DOC-EXAMPLE-BUCKET1</i>
VPC ID	<i>vpc-1a2b3c4d5e6f7g8h9</i>

Note

The Account ID parameter must be the AWS account ID of the bucket owner, which is the shared user.

```
aws s3control create-access-point --account-id 111122223333 --name example-outpost-access-point \  
--bucket arn:aws:s3-outposts:us-east-1:111122223333:outpost/op-01ac5d28a6a232904/ \  
bucket/DOC-EXAMPLE-BUCKET1 \  
--vpc-configuration VpcId=vpc-1a2b3c4d5e6f7g8h9
```

For more information about this command, see [create-access-point](#) in the *AWS CLI Reference*.

Example : Upload an object

The following example uploads the file `my_image.jpg` from the user's local file system to an object named `images/my_image.jpg` through the access point `example-outpost-access-point` on the Outpost `op-01ac5d28a6a232904`, owned by the AWS account `111122223333`. Before using this command, replace these `user input placeholder` values and the AWS Region code with the appropriate values for your use case.

```
aws s3api put-object --bucket arn:aws:s3-outposts:us-east-1:111122223333:outpost/op-01ac5d28a6a232904/accesspoint/example-outpost-access-point \
--body my_image.jpg --key images/my_image.jpg
```

For more information about this command, see [put-object](#) in the *AWS CLI Reference*.

Note

If this operation results in a Resource not found error or is unresponsive, your VPC might not have a shared endpoint.

To check whether there is a shared endpoint, use the [list-shared-endpoints](#) AWS CLI command. If there is no shared endpoint, work with the Outpost owner to create one.

For more information, see [ListSharedEndpoints](#) in the *Amazon Simple Storage Service API Reference*.

Example : Create an endpoint

The following example creates an endpoint on a shared Outpost. Before using this command, replace the `user input placeholder` values for the Outpost ID, subnet ID, and security group ID with the appropriate values for your use case.

Note

The user can perform this operation only if the resource share includes the **Outposts** resource.

```
aws s3outposts create-endpoint --outposts-id op-01ac5d28a6a232904 --subnet-id XXXXXX --security-group-id XXXXXX
```

For more information about this command, see [create-endpoint](#) in the *AWS CLI Reference*.

Other AWS services that use S3 on Outposts

Other AWS services that run local to your AWS Outposts can also use your Amazon S3 on Outposts capacity. In Amazon CloudWatch the S3Outposts namespace shows detailed metrics for buckets within S3 on Outposts, but these metrics don't include usage for other AWS services. To manage your S3 on Outposts capacity that is consumed by other AWS services, see the information in the following table.

AWS service	Description	Learn more
Amazon S3	All direct S3 on Outposts usage has a matching account and bucket CloudWatch metric.	See metrics
Amazon Elastic Block Store (Amazon EBS)	For Amazon EBS on Outposts, you can choose an AWS Outpost as your snapshot destination and store locally in your S3 on Outpost.	Learn more
Amazon Relational Database Service (Amazon RDS)	You can use Amazon RDS local backups to store your RDS backups locally on your Outpost.	Learn more

Monitoring S3 on Outposts

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

For more information about monitoring your Amazon S3 on Outposts storage capacity, see the following topics.

Topics

- [Managing S3 on Outposts capacity with Amazon CloudWatch metrics](#)
- [Receiving S3 on Outposts event notifications by using Amazon CloudWatch Events](#)
- [Monitoring S3 on Outposts with AWS CloudTrail logs](#)

Managing S3 on Outposts capacity with Amazon CloudWatch metrics

To help manage the fixed S3 capacity on your Outpost, we recommend that you create CloudWatch alerts that tell you when your storage utilization exceeds a certain threshold. For more information about the CloudWatch metrics for S3 on Outposts, see [CloudWatch metrics](#). If there is not enough space to store an object on your Outpost, the API returns an insufficient capacity exemption (ICE). To free up space, you can create CloudWatch alarms that trigger explicit data deletion, or use a lifecycle expiration policy to expire objects. To save data before deletion, you can use AWS DataSync to copy data from your Amazon S3 on Outposts bucket to an S3 bucket in an AWS Region. For more information about using DataSync, see [Getting Started with AWS DataSync](#) in the [AWS DataSync User Guide](#).

CloudWatch metrics

The S3Outposts namespace includes the following metrics for Amazon S3 on Outposts buckets. You can monitor the total number of S3 on Outposts bytes provisioned, the total free bytes available for objects, and the total size of all objects for a given bucket. Bucket or account-related metrics exist for all direct S3 usage. Indirect S3 usage, such as storing Amazon Elastic Block Store local snapshots or Amazon Relational Database Service backups on an Outpost, consumes S3 capacity, but is not included in bucket or account-related metrics. For more information about Amazon EBS local snapshots, see [Amazon EBS local snapshots on Outposts](#). To see your Amazon EBS cost report, visit <https://console.aws.amazon.com/billing/>.

Note

S3 on Outposts supports only the following metrics, and no other Amazon S3 metrics. Because S3 on Outposts has a fixed capacity limit, we recommend creating CloudWatch alarms to notify you when your storage utilization exceeds a certain threshold.

Metric	Description	Time Period	Units	Type
OutpostTotalBytes	The total provisioned capacity in bytes for an Outpost.	5 minutes	Bytes	S3 on Outposts
OutpostFreeBytes	The count of free bytes available on an Outpost to store customer data.	5 minutes	Bytes	S3 on Outposts
BucketUsedBytes	The total size of all objects for the given bucket.	5 minutes	Bytes	S3 on Outposts. Direct S3 usage only.
AccountUsedBytes	The total size of all objects for the specified Outposts account.	5 minutes	Bytes	S3 on Outposts. Direct S3 usage only.
BytesPendingReplication	The total number of bytes of objects that are pending replication for a given replication rule. For more information about how to enable replication metrics, see Creating replication rules between Outposts .	5 minutes	Bytes	Optional. For S3 Replication on Outposts.
OperationsPendingReplication	The total number of operations that are pending replication for a given replication rule. For more information about how to enable replication metrics, see Creating replication rules between Outposts .	5 minutes	Counts	Optional. For S3 Replication on Outposts.
ReplicationLatency	The current number of seconds delay by which the replication destination bucket	5 minutes	Seconds	Optional. For S3 Replication on Outposts.

Metric	Description	Time Period	Units	Type
	is behind the source bucket for a given replication rule. For more information about how to enable replication metrics, see Creating replication rules between Outposts .			

Receiving S3 on Outposts event notifications by using Amazon CloudWatch Events

You can use CloudWatch Events to create a rule for any Amazon S3 on Outposts API event. When you create a rule, you can choose to get notified through all supported CloudWatch targets, including Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), and AWS Lambda. For more information, see the list of [AWS services that can be targets for CloudWatch Events](#) in the *Amazon CloudWatch Events User Guide*. To choose a target service to work with your S3 on Outposts, see [Creating a CloudWatch Events rule that triggers on an AWS API call using AWS CloudTrail](#) in the *Amazon CloudWatch Events User Guide*.

Note

For S3 on Outposts object operations, AWS API call events sent by CloudTrail will match your rules only if you have trails (optionally with event selectors) configured to receive those events. For more information, see [Working with CloudTrail log files](#) in the *AWS CloudTrail User Guide*.

Example

The following is a sample rule for the DeleteObject operation. To use this sample rule, replace **DOC-EXAMPLE-BUCKET1** with the name of your S3 on Outposts bucket.

```
{  
  "source": [  
    "aws.s3-outposts"]}
```

```
],  
  "detail-type": [  
    "AWS API call through CloudTrail"  
,  
  "detail": {  
    "eventSource": [  
      "s3-outposts.amazonaws.com"  
,  
    "eventName": [  
      "DeleteObject"  
,  
    "requestParameters": {  
      "bucketName": [  
        "DOC-EXAMPLE-BUCKET1"  
      ]  
    }  
  }  
}
```

Monitoring S3 on Outposts with AWS CloudTrail logs

Amazon S3 on Outposts is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in S3 on Outposts. You can use AWS CloudTrail to get information about S3 on Outposts bucket-level and object-level requests to audit and log your S3 on Outposts event activity. To enable CloudTrail data events for all your Outposts buckets or for a list of specific Outposts buckets, you must [create a trail manually in CloudTrail](#). For more information about CloudTrail log file entries, see [S3 on Outposts log file entries](#).

Note

- It's a best practice to create a lifecycle policy for your AWS CloudTrail data event Outposts bucket. Configure the lifecycle policy to periodically remove log files after the period of time that you need to audit them. Doing so reduces the amount of data that Amazon Athena analyzes for each query. For more information, see [Setting lifecycle configuration on a bucket](#).
- For examples of how to query CloudTrail logs, see the AWS Big Data Blog post [Analyze Security, Compliance, and Operational Activity Using AWS CloudTrail and Amazon Athena](#).

Enable CloudTrail logging for objects in an S3 on Outposts bucket

You can use the Amazon S3 console to configure an AWS CloudTrail trail to log data events for objects in an Amazon S3 on Outposts bucket. CloudTrail supports logging S3 on Outposts object-level API operations such as `GetObject`, `DeleteObject`, and `PutObject`. These events are called *data events*.

By default, CloudTrail trails don't log data events. However, you can configure trails to log data events for S3 on Outposts buckets that you specify, or to log data events for all the S3 on Outposts buckets in your AWS account. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

CloudTrail does not populate data events in the CloudTrail event history. Additionally, not all S3 on Outposts bucket-level API operations are populated in the CloudTrail event history. For more information about how to query CloudTrail logs, see [Using Amazon CloudWatch Logs filter patterns and Amazon Athena to query CloudTrail logs](#) on the AWS Knowledge Center.

To configure a trail to log data events for an S3 on Outposts bucket, you can use either the AWS CloudTrail console or the Amazon S3 console. If you are configuring a trail to log data events for all the S3 on Outposts buckets in your AWS account, it's easier to use the CloudTrail console. For information about using the CloudTrail console to configure a trail to log S3 on Outposts data events, see [Data events](#) in the *AWS CloudTrail User Guide*.

 **Important**

Additional charges apply for data events. For more information, see [AWS CloudTrail pricing](#).

The following procedure shows how to use the Amazon S3 console to configure a CloudTrail trail to log data events for an S3 on Outposts bucket.

 **Note**

The AWS account that creates the bucket owns it and is the only one that can configure S3 on Outposts data events to be sent to AWS CloudTrail.

To enable CloudTrail data events logging for objects in an S3 on Outposts bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Outposts buckets**.
3. Choose the name of the Outposts bucket whose data events you want to log by using CloudTrail.
4. Choose **Properties**.
5. In the **AWS CloudTrail data events** section, choose **Configure in CloudTrail**.

The AWS CloudTrail console opens.

You can create a new CloudTrail trail or reuse an existing trail and configure S3 on Outposts data events to be logged in your trail.

6. On the CloudTrail console **Dashboard** page, choose **Create trail**.
7. On the **Step 1 Choose trail attributes** page, provide a name for the trail, choose an S3 bucket to store trail logs, specify any other settings that you want, and then choose **Next**.
8. On the **Step 2 Choose log events** page, under **Event type**, choose **Data events**.

For **Data event type**, choose **S3 Outposts**. Choose **Next**.

Note

- When you create a trail and configure data event logging for S3 on Outposts, you must specify the data event type correctly.
 - If you use the CloudTrail console, choose **S3 Outposts** for **Data event type**. For information about how to create trails in the CloudTrail console, see [Creating and updating a trail with the console](#) in the *AWS CloudTrail User Guide*. For information about how to configure S3 on Outposts data event logging in the CloudTrail console, see [Logging data events for Amazon S3 Objects](#) in the *AWS CloudTrail User Guide*.
 - If you use the AWS Command Line Interface (AWS CLI) or the AWS SDKs, set the `resources.type` field to `AWS::S3Outposts::Object`. For more information about how to log S3 on Outposts data events with the AWS CLI, see [Log S3 on Outposts events](#) in the *AWS CloudTrail User Guide*.

- If you use the CloudTrail console or the Amazon S3 console to configure a trail to log data events for an S3 on Outposts bucket, the Amazon S3 console shows that object-level logging is enabled for the bucket.
9. On the **Step 3 Review and create** page, review the trail attributes and the log events that you configured. Then, choose **Create trail**.

To disable CloudTrail data events logging for objects in an S3 on Outposts bucket

1. Sign in to the AWS Management Console and open the CloudTrail console at <https://console.aws.amazon.com/cloudtrail/>.
2. In the left navigation pane, choose **Trails**.
3. Choose the name of the trail that you created to log events for your S3 on Outposts bucket.
4. On the details page for your trail, choose **Stop logging** in the upper-right corner.
5. In the dialog box that appears, choose **Stop logging**.

Developing with Amazon S3 on Outposts

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts and easily store and retrieve objects on premises for applications that require local data access, local data processing, and data residency. S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS), which uses the Amazon S3 APIs, and is designed to store data durably and redundantly across multiple devices and servers on your AWS Outposts. You communicate with your Outpost bucket by using an access point and endpoint connection over a virtual private cloud (VPC). You can use the same APIs and features on Outpost buckets as you do on Amazon S3 buckets, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or REST API. For more information, see [What is Amazon S3 on Outposts?](#)

The following topics provide information about developing with S3 on Outposts.

- [Amazon S3 on Outposts API operations](#)
- [Configure the S3 control client for S3 on Outposts by using the SDK for Java](#)
- [Making requests to S3 on Outposts over IPv6](#)

Amazon S3 on Outposts API operations

This topic lists the Amazon S3, Amazon S3 Control, and Amazon S3 on Outposts API operations that you can use with Amazon S3 on Outposts.

Topics

- [Amazon S3 API operations for managing objects](#)
- [Amazon S3 Control API operations for managing buckets](#)
- [S3 on Outposts API operations for managing Outposts](#)

Amazon S3 API operations for managing objects

S3 on Outposts is designed to use the same object API operations as Amazon S3. You must use access points to access any object in an Outpost bucket. When you use an object API operation with S3 on Outposts, you provide either the Outposts access point Amazon Resource Name (ARN) or the access point alias. For more information about access point aliases, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

Amazon S3 on Outposts supports the following Amazon S3 API operations:

- [AbortMultipartUpload](#)
- [CompleteMultipartUpload](#)
- [CopyObject](#)
- [CreateMultipartUpload](#)
- [DeleteObject](#)
- [DeleteObjects](#)
- [DeleteObjectTagging](#)
- [GetObject](#)
- [GetObjectTagging](#)
- [HeadBucket](#)
- [HeadObject](#)
- [ListMultipartUploads](#)
- [ListObjects](#)
- [ListObjectsV2](#)

- [ListObjectVersions](#)
- [ListParts](#)
- [PutObject](#)
- [PutObjectTagging](#)
- [UploadPart](#)
- [UploadPartCopy](#)

Amazon S3 Control API operations for managing buckets

S3 on Outposts supports the following Amazon S3 Control API operations for working with buckets.

- [CreateAccessPoint](#)
- [CreateBucket](#)
- [DeleteAccessPoint](#)
- [DeleteAccessPointPolicy](#)
- [DeleteBucket](#)
- [DeleteBucketLifecycleConfiguration](#)
- [DeleteBucketPolicy](#)
- [DeleteBucketReplication](#)
- [DeleteBucketTagging](#)
- [GetAccessPoint](#)
- [GetAccessPointPolicy](#)
- [GetBucket](#)
- [GetBucketLifecycleConfiguration](#)
- [GetBucketPolicy](#)
- [GetBucketReplication](#)
- [GetBucketTagging](#)

- [PutAccessPointPolicy](#)

- [PutBucketLifecycleConfiguration](#)
- [PutBucketPolicy](#)
- [PutBucketReplication](#)
- [PutBucketTagging](#)
- [PutBucketVersioning](#)

S3 on Outposts API operations for managing Outposts

S3 on Outposts supports the following Amazon S3 on Outposts API operations for managing endpoints.

- [CreateEndpoint](#)
- [DeleteEndpoint](#)
- [ListEndpoints](#)
- [ListOutpostsWithS3](#)
- [ListSharedEndpoints](#)

Configure the S3 control client for S3 on Outposts by using the SDK for Java

The following example configures the Amazon S3 control client for Amazon S3 on Outposts by using the AWS SDK for Java. To use this example, replace each *user input placeholder* with your own information.

```
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;

public AWSS3Control createS3ControlClient() {

    String accessKey = AWSAccessKey;
    String secretKey = SecretAccessKey;
    BasicAWSCredentials awsCreds = new BasicAWSCredentials(accessKey, secretKey);

    return AWSS3ControlClient.builder().enableUseArnRegion()
        .withCredentials(new AWSStaticCredentialsProvider(awsCreds))
```

```
.build();  
}
```

Making requests to S3 on Outposts over IPv6

Amazon S3 on Outposts and S3 on Outposts dual-stack endpoints support requests to S3 on Outposts buckets using either the IPv6 or IPv4 protocol. With IPv6 support for S3 on Outposts, you can access and operate your buckets and control plane resources through S3 on Outposts APIs over IPv6 networks.

 **Note**

[S3 on Outposts object actions](#) (such as PutObject or GetObject) aren't supported over IPv6 networks.

There are no additional charges for accessing S3 on Outposts over IPv6 networks. For more information about S3 on Outposts, see [S3 on Outposts pricing](#).

Topics

- [Getting started with IPv6](#)
- [Using dual-stack endpoints to make requests over an IPv6 network](#)
- [Using IPv6 addresses in IAM policies](#)
- [Testing IP address compatibility](#)
- [Using IPv6 with AWS PrivateLink](#)
- [Using S3 on Outposts dual-stack endpoints](#)

Getting started with IPv6

To make a request to an S3 on Outposts bucket over IPv6, you must use a dual-stack endpoint. The next section describes how to make requests over IPv6 by using dual-stack endpoints.

The following are important considerations before trying to access an S3 on Outposts bucket over IPv6:

- The client and the network accessing the bucket must be enabled to use IPv6.

- Both virtual hosted-style and path style requests are supported for IPv6 access. For more information, see [Using S3 on Outposts dual-stack endpoints](#).
- If you use source IP address filtering in your AWS Identity and Access Management (IAM) user or S3 on Outposts bucket policies, you must update the policies to include IPv6 address ranges.

 **Note**

This requirement only applies to S3 on Outposts bucket operations and control plane resources across IPv6 networks. [Amazon S3 on Outposts object actions](#) aren't supported across IPv6 networks.

- When using IPv6, server access log files output IP addresses in an IPv6 format. You must update existing tools, scripts, and software that you use to parse S3 on Outposts log files, so that they can parse the IPv6 formatted remote IP addresses. The updated tools, scripts, and software will then correctly parse the IPv6 formatted remote IP addresses.

Using dual-stack endpoints to make requests over an IPv6 network

To make requests with S3 on Outposts API calls over IPv6, you can use dual-stack endpoints via AWS CLI or AWS SDK. The [Amazon S3 control API operations](#) and [S3 on Outposts API operations](#) work the same way whether you're accessing S3 on Outposts over an IPv6 protocol or IPv4 protocol. However, be aware that [S3 on Outposts object actions](#) (such as PutObject or GetObject) aren't supported over IPv6 networks.

When using the AWS Command Line Interface (AWS CLI) and AWS SDKs, you can use a parameter or flag to change to a dual-stack endpoint. You can also specify the dual-stack endpoint directly as an override of the S3 on Outposts endpoint in the configuration file.

You can use a dual-stack endpoint to access an S3 on Outposts bucket over IPv6 from any of the following:

- The AWS CLI, see [Using dual-stack endpoints from the AWS CLI](#).
- The AWS SDKs, see [Using S3 on Outposts dual-stack endpoints from the AWS SDKs](#).

Using IPv6 addresses in IAM policies

Before trying to access an S3 on Outposts bucket using an IPv6 protocol, make sure that IAM users or S3 on Outposts bucket policies used for IP address filtering are updated to include IPv6 address

ranges. If IP address filtering policies aren't updated to handle IPv6 addresses, you can lose access to an S3 on Outposts bucket while trying to use the IPv6 protocol.

IAM policies that filter IP addresses use [IP address condition operators](#). The following S3 on Outposts bucket policy identifies the 54.240.143.* IP range of allowed IPv4 addresses by using IP address condition operators. Any IP addresses outside of this range will be denied access to the S3 on Outposts bucket (DOC-EXAMPLE-BUCKET). Since all IPv6 addresses are outside of the allowed range, this policy prevents IPv6 addresses from being able to access DOC-EXAMPLE-BUCKET.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "IPAllow",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": "s3outposts:*",  
            "Resource": "arn:aws:s3-outposts:region:111122223333:outpost/OUTPOSTS-ID/bucket/DOC-EXAMPLE-BUCKET/*",  
            "Condition": {  
                "IpAddress": {"aws:SourceIp": "54.240.143.0/24"}  
            }  
        }  
    ]  
}
```

You can modify the S3 on Outposts bucket policy's Condition element to allow both IPv4 (54.240.143.0/24) and IPv6 (2001:DB8:1234:5678::/64) address ranges as shown in the following example. You can use the same type of Condition block shown in the example to update both your IAM user and bucket policies.

```
"Condition": {  
    "IpAddress": {  
        "aws:SourceIp": [  
            "54.240.143.0/24",  
            "2001:DB8:1234:5678::/64"  
        ]  
    }  
}
```

Before using IPv6 you must update all relevant IAM user and bucket policies that use IP address filtering to allow IPv6 address ranges. We recommend that you update your IAM policies with your organization's IPv6 address ranges in addition to your existing IPv4 address ranges. For an example of a bucket policy that allows access over both IPv6 and IPv4, see [Restrict access to specific IP addresses](#).

You can review your IAM user policies using the IAM console at <https://console.aws.amazon.com/iam/>. For more information about IAM, see the [IAM User Guide](#). For information about editing S3 on Outposts bucket policies, see [Adding or editing a bucket policy for an Amazon S3 on Outposts bucket](#).

Testing IP address compatibility

If you're using a Linux or Unix instance, or macOS X platform, you can test your access to a dual-stack endpoint over IPv6. For example, to test the connection to Amazon S3 on Outposts endpoints over IPv6, use the dig command:

```
dig s3-outposts.us-west-2.api.aws AAAA +short
```

If your dual-stack endpoint over an IPv6 network is properly set up, the dig command returns the connected IPv6 addresses. For example:

```
dig s3-outposts.us-west-2.api.aws AAAA +short  
  
2600:1f14:2588:4800:b3a9:1460:159f:ebce  
  
2600:1f14:2588:4802:6df6:c1fd:ef8a:fc76  
  
2600:1f14:2588:4801:d802:8ccf:4e04:817
```

Using IPv6 with AWS PrivateLink

S3 on Outposts supports the IPv6 protocol for AWS PrivateLink services and endpoints. With AWS PrivateLink support for the IPv6 protocol, you can connect to service endpoints within your VPC over IPv6 networks, from either on-premises or other private connections. The IPv6 support for [AWS PrivateLink for S3 on Outposts](#) also allows you to integrate AWS PrivateLink with dual-stack endpoints. For steps on how to enable IPv6 for AWS PrivateLink, see [Expedite your IPv6 adoption with AWS PrivateLink services and endpoints](#).

Note

To update the supported IP address type from IPv4 to IPv6, see [Modify the supported IP address type](#) in the *AWS PrivateLink User Guide*.

Using IPv6 with AWS PrivateLink

If you're using AWS PrivateLink with IPv6, you must create an IPv6 or dual-stack VPC interface endpoint. For general steps on how to create a VPC endpoint using the AWS Management Console, see [Access an AWS service using an interface VPC endpoint](#) in the *AWS PrivateLink User Guide*.

AWS Management Console

Use the following procedure to create an interface VPC endpoint that connects to S3 on Outposts.

1. Sign in to the AWS Management Console and open the VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**.
4. For **Service category**, choose **AWS services**.
5. For **Service name**, choose the S3 on Outposts service (**com.amazonaws.us-east-1.s3-outposts**).
6. For VPC, choose the VPC from which you'll access S3 on Outposts.
7. For **Subnets**, choose one subnet per Availability Zone from which you'll access S3 on Outposts. You can't select multiple subnets from the same Availability Zone. For each subnet that you select, a new endpoint network interface is created. By default, IP addresses from the subnet IP address ranges are assigned to the endpoint network interfaces. To designate an IP address for an endpoint network interface, choose **Designate IP addresses** and enter an IPv6 address from the subnet address range.
8. For **IP address type**, choose **Dualstack**. Assign both IPv4 and IPv6 addresses to your endpoint network interfaces. This option is supported only if all selected subnets have both IPv4 and IPv6 address ranges.
9. For **Security groups**, choose the security groups to associate with the endpoint network interfaces for the VPC endpoint. By default, the default security group is associated with the VPC.

10. For **Policy**, choose **Full access** to allow all operations by all principals on all resources over the VPC endpoint. Otherwise, choose **Custom** to attach a VPC endpoint policy that controls the permissions that principals have to perform actions on resources over the VPC endpoint. This option is available only if the service supports VPC endpoint policies. For more information, see [Endpoint policies](#).
11. (Optional) To add a tag, choose **Add new tag** and enter the tag key and the tag value.
12. Choose **Create endpoint**.

Example – S3 on Outposts bucket policy

To allow S3 on Outposts to interact with your VPC endpoints, you can then update your S3 on Outposts policy like this:

```
{  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3-outposts:*",  
            "Resource": "*",  
            "Principal": "*"  
        }  
    ]  
}
```

AWS CLI

Note

To enable the IPv6 network on your VPC endpoint, you must have IPv6 set for the SupportedIpAddressType filter for S3 on Outposts.

The following example uses the `create-vpc-endpoint` command to create a new dual-stack interface endpoint.

```
aws ec2 create-vpc-endpoint \  
--vpc-id vpc-12345678 \  
--vpc-endpoint-type Interface \  
--service-name com.amazonaws.us-east-1.s3-outposts \  
--subnet-id subnet-12345678 \  
--
```

```
--security-group-id sg-12345678 \
--ip-address-type dualstack \
--dns-options "DnsRecordIpType=dualstack"
```

Depending on the AWS PrivateLink service configuration, newly created endpoint connections might need to be accepted by the VPC endpoint service provider before they can be used. For more information, see [Accept and reject endpoint connection requests](#) in the *AWS PrivateLink User Guide*.

The following example uses the `modify-vpc-endpoint` command to update the IPv-only VPC endpoint to a dual-stack endpoint. The dual-stack endpoint allows access to both the IPv4 and IPv6 networks.

```
aws ec2 modify-vpc-endpoint \
--vpc-endpoint-id vpce-12345678 \
--add-subnet-ids subnet-12345678 \
--remove-subnet-ids subnet-12345678 \
--ip-address-type dualstack \
--dns-options "DnsRecordIpType=dualstack"
```

For more information about how to enable the IPv6 network for AWS PrivateLink, see [Expedite your IPv6 adoption with AWS PrivateLink services and endpoints](#).

Using S3 on Outposts dual-stack endpoints

S3 on Outposts dual-stack endpoints support requests to S3 on Outposts buckets over IPv6 and IPv4. This section describes how to use S3 on Outposts dual-stack endpoints.

Topics

- [S3 on Outposts dual-stack endpoints](#)
- [Using dual-stack endpoints from the AWS CLI](#)
- [Using S3 on Outposts dual-stack endpoints from the AWS SDKs](#)

S3 on Outposts dual-stack endpoints

When you make a request to a dual-stack endpoint, the S3 on Outposts bucket URL resolves to an IPv6 or an IPv4 address. For more information about accessing an S3 on Outposts bucket over IPv6, see [Making requests to S3 on Outposts over IPv6](#).

To access an S3 on Outposts bucket through a dual-stack endpoint, use a path-style endpoint name. S3 on Outposts supports only Regional dual-stack endpoint names, which means that you must specify the Region as part of the name.

For a dual-stack path-style FIPs endpoint, use the following naming convention:

```
s3-outposts-fips.region.api.aws
```

For dual-stack non-FIPS endpoint, use the following naming convention:

```
s3-outposts.region.api.aws
```

 **Note**

Virtual hosted-style endpoint names aren't supported in S3 on Outposts.

Using dual-stack endpoints from the AWS CLI

This section provides examples of AWS CLI commands used to make requests to a dual-stack endpoint. For instructions on setting up the AWS CLI, see [Getting started by using the AWS CLI and SDK for Java](#).

You set the configuration value `use_dualstack_endpoint` to `true` in a profile in your AWS Config file to direct all Amazon S3 requests made by the `s3` and `s3api` AWS CLI commands to the dual-stack endpoint for the specified Region. You specify the Region in the configuration file or in a command using the `--region` option.

When using dual-stack endpoints with the AWS CLI, only path addressing style is supported. The addressing style, set in the configuration file, determines whether the bucket name is in the hostname or in the URL. For more information, see [s3outposts](#) in the *AWS CLI User Guide*.

To use a dual-stack endpoint via the AWS CLI, use the `--endpoint-url` parameter with the `http://s3.dualstack.region.amazonaws.com` or `https://s3-outposts-fips.region.api.aws` endpoint for any `s3control` or `s3outposts` commands.

For example:

```
$ aws s3control list-regional-buckets --endpoint-url https://s3-outposts.region.api.aws
```

Using S3 on Outposts dual-stack endpoints from the AWS SDKs

This section provides examples of how to access a dual-stack endpoint by using the AWS SDKs.

AWS SDK for Java 2.x dual-stack endpoint example

The following examples show how to use the `S3ControlClient` and `S3OutpostsClient` classes to enable dual-stack endpoints when creating an S3 on Outposts client using the AWS SDK for Java 2.x. For instructions on creating and testing a working Java example for Amazon S3 on Outposts, see [Getting started by using the AWS CLI and SDK for Java](#).

Example – Create an `S3ControlClient` class with dual-stack endpoints enabled

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListRegionalBucketsRequest;
import software.amazon.awssdk.services.s3control.model.ListRegionalBucketsResponse;
import software.amazon.awssdk.services.s3control.model.S3ControlException;

public class DualStackEndpointsExample1 {

    public static void main(String[] args) {
        Region clientRegion = Region.of("us-east-1");
        String accountId = "111122223333";
        String navyId = "9876543210";

        try {
            // Create an S3ControlClient with dual-stack endpoints enabled.
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(clientRegion)
                .dualstackEnabled(true)
                .build();

            ListRegionalBucketsRequest listRegionalBucketsRequest =
            ListRegionalBucketsRequest.builder()

                .accountId(accountId)

                .outpostId(navyId)

            .build();
        }
    }
}
```

```
        ListRegionalBucketsResponse listBuckets =
s3ControlClient.listRegionalBuckets(listRegionalBucketsRequest);
        System.out.printf("ListRegionalBuckets Response: %s%n",
listBuckets.toString());
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 on Outposts
couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    }
    catch (S3ControlException e) {
        // Unknown exceptions will be thrown as an instance of this type.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 on Outposts couldn't be contacted for a response, or the
client
        // couldn't parse the response from Amazon S3 on Outposts.
        e.printStackTrace();
    }
}
}
```

Example – Create an `S3OutpostsClient` with dual-stack endpoints enabled

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3outposts.S3OutpostsClient;
import software.amazon.awssdk.services.s3outposts.model.ListEndpointsRequest;
import software.amazon.awssdk.services.s3outposts.model.ListEndpointsResponse;
import software.amazon.awssdk.services.s3outposts.model.S3OutpostsException;

public class DualStackEndpointsExample2 {

    public static void main(String[] args) {
        Region clientRegion = Region.of("us-east-1");

        try {
            // Create an S3OutpostsClient with dual-stack endpoints enabled.
            S3OutpostsClient s3outpostsClient = S3OutpostsClient.builder()
                .region(clientRegion)
```

```
        .dualstackEnabled(true)
        .build();

    ListEndpointsRequest listEndpointsRequest =
ListEndpointsRequest.builder().build();

    ListEndpointsResponse listEndpoints =
s30outpostsClient.listEndpoints(listEndpointsRequest);
    System.out.printf("ListEndpoints Response: %s%n",
listEndpoints.toString());
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 on Outposts
couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
}
catch (S30outpostsException e) {
    // Unknown exceptions will be thrown as an instance of this type.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 on Outposts couldn't be contacted for a response, or the
client
    // couldn't parse the response from Amazon S3 on Outposts.
    e.printStackTrace();
}
}
```

If you're using the AWS SDK for Java 2.x on Windows, you might have to set the following Java virtual machine (JVM) property:

```
java.net.preferIPv6Addresses=true
```

Code examples for Amazon S3 using AWS SDKs

The following code examples show how to use Amazon S3 with an AWS software development kit (SDK).

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Cross-service examples are sample applications that work across multiple AWS services.

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello Amazon S3

The following code examples show how to get started using Amazon S3.

C++

SDK for C++

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.  
cmake_minimum_required(VERSION 3.13)  
  
# Set the AWS service components used by this project.  
set(SERVICE_COMPONENTS s3)
```

```
# Set this project's name.  
project("hello_s3")  
  
# Set the C++ standard to use to build this target.  
# At least C++ 11 is required for the AWS SDK for C++.  
set(CMAKE_CXX_STANDARD 11)  
  
# Use the MSVC variable to determine if this is a Windows build.  
set(WINDOWS_BUILD ${MSVC})  
  
if (WINDOWS_BUILD) # Set the location where CMake can find the installed  
libraries for the AWS SDK.  
    string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH  
"${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")  
    list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})  
endif ()  
  
# Find the AWS SDK for C++ package.  
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})  
  
if (WINDOWS_BUILD)  
    # Copy relevant AWS SDK for C++ libraries into the current binary directory  
    # for running and debugging.  
  
    # set(BIN_SUB_DIR "/Debug") # if you are building from the command line you  
    # may need to uncomment this  
    # and set the proper subdirectory to the executables' location.  
  
    AWSSDK_CPY_DYN_LIBS(SERVICE_COMPONENTS ""  
${CMAKE_CURRENT_BINARY_DIR}${BIN_SUB_DIR})  
endif ()  
  
add_executable(${PROJECT_NAME}  
    hello_s3.cpp)  
  
target_link_libraries(${PROJECT_NAME}  
    ${AWSSDK_LINK_LIBRARIES})
```

Code for the `hello_s3.cpp` source file.

```
#include <aws/core/Aws.h>
```

```
#include <aws/s3/S3Client.h>
#include <iostream>
#include <aws/core/auth/AWSCredentialsProviderChain.h>
using namespace Aws;
using namespace Aws::Auth;

/*
 * A "Hello S3" starter application which initializes an Amazon Simple Storage
 * Service (Amazon S3) client
 * and lists the Amazon S3 buckets in the selected region.
 *
 * main function
 *
 * Usage: 'hello_s3'
 */
int main(int argc, char **argv) {
    Aws::SDKOptions options;
    // Optionally change the log level for debugging.
//    options.loggingOptions.logLevel = Utils::Logging::LogLevel::Debug;
    Aws::InitAPI(options); // Should only be called once.
    int result = 0;
    {
        Aws::Client::ClientConfiguration clientConfig;
        // Optional: Set to the AWS Region (overrides config file).
        // clientConfig.region = "us-east-1";

        // You don't normally have to test that you are authenticated. But the
        // S3 service permits anonymous requests, thus the s3Client will return "success"
        // and 0 buckets even if you are unauthenticated, which can be confusing to a new
        // user.
        auto provider =
            Aws::MakeShared<DefaultAWSCredentialsProviderChain>("alloc-tag");
        auto creds = provider->GetAWSCredentials();
        if (creds.IsEmpty()) {
            std::cerr << "Failed authentication" << std::endl;
        }

        Aws::S3::S3Client s3Client(clientConfig);
        auto outcome = s3Client.ListBuckets();

        if (!outcome.IsSuccess()) {
```

```
        std::cerr << "Failed with error: " << outcome.GetError() <<
std::endl;
        result = 1;
    } else {
        std::cout << "Found " << outcome.GetResult().GetBuckets().size()
            << " buckets\n";
        for (auto &bucket: outcome.GetResult().GetBuckets()) {
            std::cout << bucket.GetName() << std::endl;
        }
    }
}

Aws::ShutdownAPI(options); // Should only be called once.
return result;
}
```

- For API details, see [ListBuckets](#) in *AWS SDK for C++ API Reference*.

Go

SDK for Go V2

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
package main

import (
    "context"
    "fmt"

    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/s3"
)

// main uses the AWS SDK for Go V2 to create an Amazon Simple Storage Service
// (Amazon S3) client and list up to 10 buckets in your account.
```

```
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
    sdkConfig, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        fmt.Println("Couldn't load default configuration. Have you set up your AWS
account?")
        fmt.Println(err)
        return
    }
    s3Client := s3.NewFromConfig(sdkConfig)
    count := 10
    fmt.Printf("Let's list up to %v buckets for your account.\n", count)
    result, err := s3Client.ListBuckets(context.TODO(), &s3.ListBucketsInput{})
    if err != nil {
        fmt.Printf("Couldn't list buckets for your account. Here's why: %v\n", err)
        return
    }
    if len(result.Buckets) == 0 {
        fmt.Println("You don't have any buckets!")
    } else {
        if count > len(result.Buckets) {
            count = len(result.Buckets)
        }
        for _, bucket := range result.Buckets[:count] {
            fmt.Printf("\t%v\n", *bucket.Name)
        }
    }
}
```

- For API details, see [ListBuckets in AWS SDK for Go API Reference](#).

Java

SDK for Java 2.x

Add CORS rules to an Amazon S3 bucket using an AWS SDK

The following code examples show how to add cross-origin resource sharing (CORS) rules to an S3 bucket.

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Add CORS configuration to the Amazon S3 bucket.
/// </summary>
/// <param name="client">The initialized Amazon S3 client object used
/// to apply the CORS configuration to an Amazon S3 bucket.</param>
/// <param name="configuration">The CORS configuration to apply.</param>
private static async Task PutCORSConfigurationAsync(AmazonS3Client
    client, CORSConfiguration configuration)
```

```
    {
        PutCORSConfigurationRequest request = new
PutCORSConfigurationRequest()
{
    BucketName = BucketName,
    Configuration = configuration,
};

    _ = await client.PutCORSConfigurationAsync(request);
}
```

- For API details, see [PutBucketCors](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

The following example enables PUT, POST, and DELETE requests from `www.example.com`, and enables GET requests from any domain:

```
aws s3api put-bucket-cors --bucket MyBucket --cors-configuration file://cors.json

cors.json:
{
    "CORSRules": [
        {
            "AllowedOrigins": ["http://www.example.com"],
            "AllowedHeaders": ["*"],
            "AllowedMethods": ["PUT", "POST", "DELETE"],
            "MaxAgeSeconds": 3000,
            "ExposeHeaders": ["x-amz-server-side-encryption"]
        },
        {
            "AllowedOrigins": ["*"],
            "AllowedHeaders": ["Authorization"],
            "AllowedMethods": ["GET"],
            "MaxAgeSeconds": 3000
        }
    ]
}
```

- For API details, see [PutBucketCors](#) in *AWS CLI Command Reference*.

Add a lifecycle configuration to an Amazon S3 bucket using an AWS SDK

The following code examples show how to add a lifecycle configuration to an S3 bucket.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Work with versioned objects](#)

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>  
/// Adds lifecycle configuration information to the S3 bucket named in  
/// the bucketName parameter.  
/// </summary>  
/// <param name="client">The S3 client used to call the
```

```
    ///> PutLifecycleConfigurationAsync method.</param>
    ///> <param name="bucketName">A string representing the S3 bucket to
    ///> which configuration information will be added.</param>
    ///> <param name="configuration">A LifecycleConfiguration object that
    ///> will be applied to the S3 bucket.</param>
    public static async Task AddExampleLifecycleConfigAsync(IAmazonS3 client,
string bucketName, LifecycleConfiguration configuration)
{
    var request = new PutLifecycleConfigurationRequest()
    {
        BucketName = bucketName,
        Configuration = configuration,
    };
    var response = await client.PutLifecycleConfigurationAsync(request);
}
```

- For API details, see [PutBucketLifecycleConfiguration](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

The following command applies a lifecycle configuration to a bucket named my-bucket:

```
aws s3api put-bucket-lifecycle-configuration --bucket my-bucket --lifecycle-
configuration file://lifecycle.json
```

The file `lifecycle.json` is a JSON document in the current folder that specifies two rules:

```
{
    "Rules": [
        {
            "ID": "Move rotated logs to Glacier",
            "Prefix": "rotated/",
            "Status": "Enabled",
            "Transitions": [
                {
                    "Date": "2015-11-10T00:00:00.000Z",
                    "StorageClass": "GLACIER"
                }
            ]
        }
    ]
}
```

```
        ],
    },
    {
        "Status": "Enabled",
        "Prefix": "",
        "NoncurrentVersionTransitions": [
            {
                "NoncurrentDays": 2,
                "StorageClass": "GLACIER"
            }
        ],
        "ID": "Move old versions to Glacier"
    }
]
```

The first rule moves files with the prefix rotated to Glacier on the specified date. The second rule moves old object versions to Glacier when they are no longer current. For information on acceptable timestamp formats, see *Specifying Parameter Values in the AWS CLI User Guide*.

- For API details, see [PutBucketLifecycleConfiguration](#) in *AWS CLI Command Reference*.

Add a policy to an Amazon S3 bucket using an AWS SDK

The following code examples show how to add a policy to an S3 bucket.

C++

SDK for C++

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
bool AwsDoc::S3::PutBucketPolicy(const Aws::String &bucketName,
                                  const Aws::String &policyBody,
                                  const Aws::Client::ClientConfiguration
&clientConfig) {
    Aws::S3::S3Client s3_client(clientConfig);

    std::shared_ptr<Aws::StringStream> request_body =
        Aws::MakeShared<Aws::StringStream>("");
    *request_body << policyBody;

    Aws::S3::Model::PutBucketPolicyRequest request;
    request.SetBucket(bucketName);
```

```
request.SetBody(request_body);

Aws::S3::Model::PutBucketPolicyOutcome outcome =
    s3_client.PutBucketPolicy(request);

if (!outcome.IsSuccess()) {
    std::cerr << "Error: PutBucketPolicy: "
        << outcome.GetError().GetMessage() << std::endl;
}
else {
    std::cout << "Set the following policy body for the bucket '" <<
        bucketName << "'" << std::endl << std::endl;
    std::cout << policyBody << std::endl;
}

return outcome.IsSuccess();
}

//! Build a policy JSON string.
/*! \sa GetPolicyString()
 * \param userArn Aws user Amazon Resource Name (ARN).
 *   For more information, see https://docs.aws.amazon.com/IAM/latest/UserGuide/reference\_identifiers.html#identifiers-arns.
 * \param bucketName Name of a bucket.
 */
Aws::String GetPolicyString(const Aws::String &userArn,
                           const Aws::String &bucketName) {
    return
        "{\n"
        "  \"Version\": \"2012-10-17\", \n"
        "  \"Statement\": [\n"
        "    {\n"
        "      \"Sid\": \"1\", \n"
        "      \"Effect\": \"Allow\", \n"
        "      \"Principal\": {\n"
        "        \"AWS\": \""
        + userArn +
        "\",\n"
        "      },\n"
        "      \"Action\": [ \"s3:GetObject\" ],\n"
        "      \"Resource\": [ \"arn:aws:s3:::"
        + bucketName +
        "\" ]\n"
    
```

```
    "/*\" ]\n"
     "      }\n"
     "    ]\n"
  "}";
}
```

- For API details, see [PutBucketPolicy](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

This example allows all users to retrieve any object in *MyBucket* except those in the *MySecretFolder*. It also grants put and delete permission to the root user of the AWS account 1234-5678-9012:

```
aws s3api put-bucket-policy --bucket MyBucket --policy file://policy.json

policy.json:
{
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": "*",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::MyBucket/*"
    },
    {
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::MyBucket/MySecretFolder/*"
    },
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:root"
      },
      "Action": [
        "s3:DeleteObject",
        "s3:PutObject"
      ]
    }
  ]
}
```

```
        ],
        "Resource": "arn:aws:s3:::MyBucket/*"
    }
]
```

- For API details, see [PutBucketPolicy](#) in *AWS CLI Command Reference*.

Add the policy.

```
import { PutBucketPolicyCommand, S3Client } from "@aws-sdk/client-s3";

const client = new S3Client({});

export const main = async () => {
  const command = new PutBucketPolicyCommand({
    Policy: JSON.stringify({
      Version: "2012-10-17",
      Statement: [
        {
          Sid: "AllowGetObject",
          // Allow this particular user to call GetObject on any object in this
          bucket.
          Effect: "Allow",
          Principal: {
            AWS: "arn:aws:iam::ACCOUNT-ID:user/USERNAME",
          },
          Action: "s3:GetObject",
          Resource: "arn:aws:s3:::BUCKET-NAME/*",
        },
      ],
    }),
    // Apply the preceding policy to this bucket.
    Bucket: "BUCKET-NAME",
  });

  try {
    const response = await client.send(command);
    console.log(response);
  } catch (err) {
    console.error(err);
  }
}
```

```
    }  
};
```

Cancel multipart uploads using an AWS SDK

The following code example shows how to cancel multipart uploads.

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
using System;
using System.Threading.Tasks;
using Amazon.S3;
using Amazon.S3.Transfer;

/// <summary>
/// This example shows how to use the Amazon Simple Storage Service
/// (Amazon S3) to stop a multi-part upload process using the Amazon S3
/// TransferUtility.
/// </summary>
public class AbortMPU
{
    public static async Task Main()
    {
        string bucketName = "doc-example-bucket";

        // If the AWS Region defined for your default user is different
        // from the Region where your Amazon S3 bucket is located,
        // pass the Region name to the S3 client object's constructor.
```

```
// For example: RegionEndpoint.USWest2.  
IAmazonS3 client = new AmazonS3Client();  
  
    await AbortMPUAsync(client, bucketName);  
}  
  
/// <summary>  
/// Cancels the multi-part copy process.  
/// </summary>  
/// <param name="client">The initialized client object used to create  
/// the TransferUtility object.</param>  
/// <param name="bucketName">The name of the S3 bucket where the  
/// multi-part copy operation is in progress.</param>  
public static async Task AbortMPUAsync(IAmazonS3 client, string  
bucketName)  
{  
    try  
    {  
        var transferUtility = new TransferUtility(client);  
  
        // Cancel all in-progress uploads initiated before the specified  
date.  
        await transferUtility.AbortMultipartUploadsAsync(  
            bucketName, DateTime.Now.AddDays(-7));  
    }  
    catch (AmazonS3Exception e)  
    {  
        Console.WriteLine($"Error: {e.Message}");  
    }  
}
```

- For API details, see [AbortMultipartUploads](#) in *AWS SDK for .NET API Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Complete a multipart upload action using an AWS SDK

The following code examples show how to complete a multipart upload action.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Perform a multipart copy](#)
- [Perform a multipart upload](#)
- [Use checksums](#)

CLI

AWS CLI

The following command completes a multipart upload for the key `multipart/01` in the bucket `my-bucket`:

```
aws s3api complete-multipart-upload --multipart-upload file://
mpustruct --bucket my-bucket --key 'multipart/01' --upload-id
dfRtDYU0WWCCcH43C3WFbkRONycyCpTJJvxu2i5GYkZljF.Yxwh6XG7WfS2vC4to6HiV6Yjlx.cph0gtNBtJ8P3U
```

The upload ID required by this command is output by `create-multipart-upload` and can also be retrieved with `list-multipart-uploads`.

The multipart upload option in the above command takes a JSON structure that describes the parts of the multipart upload that should be reassembled into the complete file. In this example, the `file://` prefix is used to load the JSON structure from a file in the local folder named `mpustruct`.

`mpustruct`:

```
{
  "Parts": [
    {
      "ETag": "e868e0f4719e394144ef36531ee6824c",
      "PartNumber": 1
    },
    {
      "ETag": "6bb2b12753d66fe86da4998aa33fffb0",
      "PartNumber": 2
    }
  ]
}
```

```
},
{
    "ETag": "d0a0112e841abec9c9ec83406f0159c8",
    "PartNumber": 3
}
]
```

The ETag value for each part is output each time you upload a part using the `upload-part` command and can also be retrieved by calling `list-parts` or calculated by taking the MD5 checksum of each part.

Output:

```
{
    "ETag": "\"3944a9f7a4faab7f78788ff6210f63f0-3\"",
    "Bucket": "my-bucket",
    "Location": "https://my-bucket.s3.amazonaws.com/multipart%2F01",
    "Key": "multipart/01"
}
```

- For API details, see [CompleteMultipartUpload](#) in *AWS CLI Command Reference*.

Rust

SDK for Rust

 **Note**

Create an Amazon S3 Multi-Region Access Point using an AWS SDK

The following code example shows how to create an Amazon S3 Multi-Region Access Point.

Kotlin

SDK for Kotlin

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Configure the S3 control client to send request to the us-west-2 Region.

```
suspend fun createS3ControlClient(): S3ControlClient {  
    // Configure your S3ControlClient to send requests to US West  
(Oregon).  
    val s3Control = S3ControlClient.fromEnvironment {  
        region = "us-west-2"  
    }  
    return s3Control  
}
```

Create the Multi-Region Access Point.

```
suspend fun createMrap(s3Control: S3ControlClient, accountIdParam: String,  
bucketName1: String, bucketName2: String, mrapName: String): String {  
    println("Creating MRAP ...")  
    val createMrapResponse: CreateMultiRegionAccessPointResponse =  
s3Control.createMultiRegionAccessPoint {  
    accountId = accountIdParam  
    clientToken = UUID.randomUUID().toString()  
    details {  
        name = mrapName  
  
        regions = listOf(  
            Region {  
                bucket = bucketName1  
            },  
            Region {  
                bucket = bucketName2  
            }  
        )  
    }  
}  
val requestToken: String? = createMrapResponse.requestTokenArn  
  
// Use the request token to check for the status of the  
CreateMultiRegionAccessPoint operation.  
if (requestToken != null) {  
    waitForSucceededStatus(s3Control, requestToken, accountIdParam)  
    println("MRAP created")  
}
```

```
    val getMrapResponse = s3Control.getMultiRegionAccessPoint(
        input = GetMultiRegionAccessPointRequest {
            accountId = accountIdParam
            name = mrapName
        }
    )
    val mrapAlias = getMrapResponse.accessPoint?.alias
    return "arn:aws:s3:::$accountIdParam:accesspoint/$mrapAlias"
}
```

Wait for the Multi-Region Access Point to become available.

```
suspend fun waitForSucceededStatus(s3Control: S3ControlClient,
requestToken: String, accountIdParam: String, timeBetweenChecks: Duration =
1.minutes) {
    var describeResponse: DescribeMultiRegionAccessPointOperationResponse
    describeResponse = s3Control.describeMultiRegionAccessPointOperation(
        input = DescribeMultiRegionAccessPointOperationRequest {
            accountId = accountIdParam
            requestTokenArn = requestToken
        }
    )

    var status: String? = describeResponse.asyncOperation?.requestStatus
    while (status != "SUCCEEDED") {
        delay(timeBetweenChecks)
        describeResponse =
s3Control.describeMultiRegionAccessPointOperation(
            input = DescribeMultiRegionAccessPointOperationRequest {
                accountId = accountIdParam
                requestTokenArn = requestToken
            }
        )
        status = describeResponse.asyncOperation?.requestStatus
        println(status)
    }
}
```

CLI

AWS CLI

Example 1: To create a bucket

The following `create-bucket` example creates a bucket named `my-bucket`:

```
aws s3api create-bucket \
    --bucket my-bucket \
    --region us-east-1
```

Output:

```
{
    "Location": "/my-bucket"
}
```

For more information, see [Creating a bucket](#) in the *Amazon S3 User Guide*.

Example 2: To create a bucket with owner enforced

The following `create-bucket` example creates a bucket named `my-bucket` that uses the bucket owner enforced setting for S3 Object Ownership.

```
aws s3api create-bucket \
    --bucket my-bucket \
    --region us-east-1 \
    --object-ownership BucketOwnerEnforced
```

Output:

```
{
```

```
        "Location": "/my-bucket"  
    }
```

For more information, see [Controlling ownership of objects and disabling ACLs](#) in the *Amazon S3 User Guide*.

Example 3: To create a bucket outside of the ``us-east-1`` region

The following `create-bucket` example creates a bucket named `my-bucket` in the `eu-west-1` region. Regions outside of `us-east-1` require the appropriate `LocationConstraint` to be specified in order to create the bucket in the desired region.

```
aws s3api create-bucket \  
  --bucket my-bucket \  
  --region eu-west-1 \  
  --create-bucket-configuration LocationConstraint=eu-west-1
```

Output:

```
{  
    "Location": "http://my-bucket.s3.amazonaws.com/"  
}
```

For more information, see [Creating a bucket](#) in the *Amazon S3 User Guide*.

- For API details, see [CreateBucket](#) in *AWS CLI Command Reference*.

SDK for Python (Boto3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a bucket with default settings.

```
class BucketWrapper:  
    """Encapsulates S3 bucket actions."""  
  
    def __init__(self, bucket):  
        """  
        :param bucket: A Boto3 Bucket resource. This is a high-level resource in  
        Boto3  
                    that wraps bucket actions in a class-like structure.  
        """  
        self.bucket = bucket  
        self.name = bucket.name  
  
    def create(self, region_override=None):  
        """  
        Create an Amazon S3 bucket in the default Region for the account or in  
        the  
                    specified Region.  
  
        :param region_override: The Region in which to create the bucket. If this  
        is  
                    not specified, the Region configured in your  
        shared  
                    credentials is used.  
        """  
        if region_override is not None:  
            region = region_override  
        else:  
            region = self.bucket.meta.client.meta.region_name  
        try:
```

```
        self.bucket.create(CreateBucketConfiguration={"LocationConstraint":  
region})  
  
        self.bucket.wait_until_exists()  
        logger.info("Created bucket '%s' in region=%s", self.bucket.name,  
region)  
    except ClientError as error:  
        logger.exception(  
            "Couldn't create bucket named '%s' in region=%s.",  
            self.bucket.name,  
            region,  
        )  
        raise error
```

Create a versioned bucket with a lifecycle configuration.

```
def create_versioned_bucket(bucket_name, prefix):  
    """  
    Creates an Amazon S3 bucket, enables it for versioning, and configures a  
    lifecycle  
    that expires noncurrent object versions after 7 days.  
  
    Adding a lifecycle configuration to a versioned bucket is a best practice.  
    It helps prevent objects in the bucket from accumulating a large number of  
    noncurrent versions, which can slow down request performance.  
  
    Usage is shown in the usage_demo_single_object function at the end of this  
    module.  
  
    :param bucket_name: The name of the bucket to create.  
    :param prefix: Identifies which objects are automatically expired under the  
                  configured lifecycle rules.  
    :return: The newly created bucket.  
    """  
  
    try:  
        bucket = s3.create_bucket(  
            Bucket=bucket_name,  
            CreateBucketConfiguration={  
                "LocationConstraint": s3.meta.client.meta.region_name  
            },  
        )
```

```
        logger.info("Created bucket %s.", bucket.name)
    except ClientError as error:
        if error.response["Error"]["Code"] == "BucketAlreadyOwnedByYou":
            logger.warning("Bucket %s already exists! Using it.", bucket_name)

Create a multipart upload structure using an AWS SDK

The following code examples show how to create the structure to build a multipart upload action.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Perform a multipart copy](#)
- [Perform a multipart upload](#)
- [Use checksums](#)

CLI

AWS CLI

The following command creates a multipart upload in the bucket my-bucket with the key multipart/01:

```
aws s3api create-multipart-upload --bucket my-bucket --key 'multipart/01'
```

Output:

```
{  
    "Bucket": "my-bucket",  
    "UploadId":  
    "dfRtDYU0WWCCcH43C3WFbkR0NycyCpTJJvxu2i5GYkZ1jF.Yxwh6XG7WfS2vC4to6HiV6Yjlx.cph0gtNBtJ8P3  
    "Key": "multipart/01"  
}
```

The completed file will be named 01 in a folder called multipart in the bucket my-bucket. Save the upload ID, key and bucket name for use with the upload-part command.

- For API details, see [CreateMultipartUpload](#) in *AWS CLI Command Reference*.

Rust

SDK for Rust

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
let multipart_upload_res: CreateMultipartUploadOutput = client
```

```
.create_multipart_upload()  
.bucket(&bucket_name)  
.key(&key)  
.send()  
.await  
.unwrap();
```

- For API details, see [CreateMultipartUpload](#) in *AWS SDK for Rust API reference*.

Delete multiple objects from an Amazon S3 bucket using an AWS SDK

The following code examples show how to delete multiple objects from an S3 bucket.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with buckets and objects](#)

.NET

AWS SDK for .NET

 **Note**

CLI

AWS CLI

The following command deletes an object from a bucket named my-bucket:

```
aws s3api delete-objects --bucket my-bucket --delete file://delete.json
```

delete.json is a JSON document in the current directory that specifies the object to delete:

```
{  
    "Objects": [  
        {  
            "Key": "test1.txt"  
        }  
    ],  
    "Quiet": false  
}
```

Output:

```
{  
    "Deleted": [  
        {  
            "DeleteMarkerVersionId": "mYAT5Mc6F7aeUL8SS7FAAqUP01koHwzU",  
            "Key": "test1.txt",  
            "DeleteMarker": true  
        }  
    ]  
}
```

- For API details, see [DeleteObjects](#) in *AWS CLI Command Reference*.

Determine the existence and content type of an object in an Amazon S3 bucket using an AWS SDK

The following code examples show how to determine the existence and content type of an object in an S3 bucket.

CLI

AWS CLI

The following command retrieves metadata for an object in a bucket named my-bucket:

```
aws s3api head-object --bucket my-bucket --key index.html
```

Output:

```
{  
    "AcceptRanges": "bytes",  
    "ContentType": "text/html",  
    "LastModified": "Thu, 16 Apr 2015 18:19:14 GMT",  
    "ContentLength": 77,  
    "VersionId": "null",  
    "ETag": "\"30a6ec7e1a9ad79c203d05a589c8b400\"",  
    "Metadata": {}  
}
```

- For API details, see [HeadObject](#) in *AWS CLI Command Reference*.

Determine the existence of an Amazon S3 bucket using an AWS SDK

The following code examples show how to determine the existence of an S3 bucket.

Bash

AWS CLI with Bash script

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
#####
# function bucket_exists
#
# This function checks to see if the specified bucket already exists.
#
# Parameters:
#     $1 - The name of the bucket to check.
#
# Returns:
#     0 - If the bucket already exists.
#     1 - If the bucket doesn't exist.
#####
function bucket_exists() {
    local bucket_name
    bucket_name=$1
```

```
# Check whether the bucket already exists.  
# We suppress all output - we're interested only in the return code.  
  
if aws s3api head-bucket \  
    --bucket "$bucket_name" \  
    >/dev/null 2>&1; then  
    return 0 # 0 in Bash script means true.  
else  
    return 1 # 1 in Bash script means false.  
fi  
}
```

- For API details, see [HeadBucket](#) in *AWS CLI Command Reference*.

CLI

AWS CLI

The following command verifies access to a bucket named my-bucket:

```
aws s3api head-bucket --bucket my-bucket
```

If the bucket exists and you have access to it, no output is returned. Otherwise, an error message will be shown. For example:

```
A client error (404) occurred when calling the HeadBucket operation: Not Found
```

- For API details, see [HeadBucket](#) in *AWS CLI Command Reference*.

Go

Enable notifications for an Amazon S3 bucket using an AWS SDK

The following code examples show how to enable notifications for an S3 bucket.

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.S3;
using Amazon.S3.Model;

/// <summary>
/// This example shows how to enable notifications for an Amazon Simple
/// Storage Service (Amazon S3) bucket.
/// </summary>
public class EnableNotifications
{
    public static async Task Main()
    {
        const string bucketName = "doc-example-bucket1";
        const string snsTopic = "arn:aws:sns:us-east-2:0123456789ab:bucket-
notify";
        const string sqsQueue = "arn:aws:sqs:us-
east-2:0123456789ab:Example_Queue";

        IAmazonS3 client = new AmazonS3Client(Amazon.RegionEndpoint.USEast2);
        await EnableNotificationAsync(client, bucketName, snsTopic,
        sqsQueue);
    }

    /// <summary>
    /// This method makes the call to the PutBucketNotificationAsync method.
    /// </summary>
```

```
/// <param name="client">An initialized Amazon S3 client used to call
/// the PutBucketNotificationAsync method.</param>
/// <param name="bucketName">The name of the bucket for which
/// notifications will be turned on.</param>
/// <param name="snsTopic">The ARN for the Amazon Simple Notification
/// Service (Amazon SNS) topic associated with the S3 bucket.</param>
/// <param name="sqSQueue">The ARN of the Amazon Simple Queue Service
/// (Amazon SQS) queue to which notifications will be pushed.</param>
public static async Task EnableNotificationAsync(
    IAmazonS3 client,
    string bucketName,
    string snsTopic,
    string sqsQueue)
{
    try
    {
        // The bucket for which we are setting up notifications.
        var request = new PutBucketNotificationRequest()
        {
            BucketName = bucketName,
        };

        // Defines the topic to use when sending a notification.
        var topicConfig = new TopicConfiguration()
        {
            Events = new List<EventType> { EventType.ObjectCreatedCopy },
            Topic = snsTopic,
        };
        request.TopicConfigurations = new List<TopicConfiguration>
        {
            topicConfig,
        };
        request.QueueConfigurations = new List<QueueConfiguration>
        {
            new QueueConfiguration()
            {
                Events = new List<EventType>
                { EventType.ObjectCreatedPut },
                Queue = sqsQueue,
            },
        };

        // Now apply the notification settings to the bucket.
    }
}
```

```
        PutBucketNotificationResponse response = await
client.PutBucketNotificationAsync(request);
    }
    catch (AmazonS3Exception ex)
    {
        Console.WriteLine($"Error: {ex.Message}");
    }
}
```

- For API details, see [PutBucketNotificationConfiguration](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

The applies a notification configuration to a bucket named my-bucket:

```
aws s3api put-bucket-notification --bucket my-bucket --notification-configuration
file://notification.json
```

The file notification.json is a JSON document in the current folder that specifies an SNS topic and an event type to monitor:

```
{
    "TopicConfiguration": {
        "Event": "s3:ObjectCreated:*",
        "Topic": "arn:aws:sns:us-west-2:123456789012:s3-notification-topic"
    }
}
```

The SNS topic must have an IAM policy attached to it that allows Amazon S3 to publish to it:

```
{
    "Version": "2008-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Action": "sns:Publish",
            "Resource": "arn:aws:sns:us-west-2:123456789012:s3-notification-topic"
        }
    ]
}
```

```
"Principal": {  
    "Service": "s3.amazonaws.com"  
},  
"Action": [  
    "SNS:Publish"  
],  
"Resource": "arn:aws:sns:us-west-2:123456789012:my-bucket",  
"Condition": {  
    "ArnLike": {  
        "aws:SourceArn": "arn:aws:s3:::*:my-bucket"  
    }  
}  
}  
]  
}
```

- For API details, see [PutBucketNotificationConfiguration](#) in *AWS CLI Command Reference*.

Get CORS rules for an Amazon S3 bucket using an AWS SDK

The following code examples show how to get cross-origin resource sharing (CORS) rules for an S3 bucket.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Retrieve the CORS configuration applied to the Amazon S3 bucket.
/// </summary>
/// <param name="client">The initialized Amazon S3 client object used
/// to retrieve the CORS configuration.</param>
/// <returns>The created CORS configuration object.</returns>
private static async Task<CORSConfiguration>
RetrieveCORSConfigurationAsync(AmazonS3Client client)
{
    GetCORSConfigurationRequest request = new
GetCORSConfigurationRequest()
    {
        BucketName = BucketName,
    };
    var response = await client.GetCORSConfigurationAsync(request);
    var configuration = response.Configuration;
    PrintCORSRules(configuration);
    return configuration;
}
```

- For API details, see [GetBucketCors](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

The following command retrieves the Cross-Origin Resource Sharing configuration for a bucket named my-bucket:

```
aws s3api get-bucket-cors --bucket my-bucket
```

Output:

```
{  
    "CORSRules": [  
        {  
            "AllowedHeaders": [  
                "*"  
            ],  
            "ExposeHeaders": [  
                "x-amz-server-side-encryption"  
            ],  
            "AllowedMethods": [  
                "PUT",  
                "POST",  
                "DELETE"  
            ],  
            "MaxAgeSeconds": 3000,  
            "AllowedOrigins": [  
                "http://www.example.com"  
            ]  
        },  
        {  
            "AllowedHeaders": [  
                "Authorization"  
            ],  
            "MaxAgeSeconds": 3000,  
            "AllowedMethods": [  
                "GET"  
            ],  
            "AllowedOrigins": [  
                "*"  
            ]  
        }  
    ]  
}
```

```
}
```

Get an Amazon S3 object from a Multi-Region Access Point by using an AWS SDK

The following code example shows how to get an object from a Multi-Region Access Point.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Get started with buckets and objects](#)
- [Get started with encryption](#)

Kotlin

SDK for Kotlin

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Configure the S3 client to use the Asymmetric Sigv4 (Sigv4a) signing algorithm.

```
suspend fun createS3Client(): S3Client {  
    // Configure your S3Client to use the Asymmetric Sigv4 (Sigv4a)  
    // signing algorithm.  
    val sigV4AScheme = SigV4AsymmetricAuthScheme(CrtAwsSigner)
```

```
    val s3 = S3Client.fromEnvironment {
        authSchemes = listOf(sigV4AScheme)
    }
    return s3
}
```

Use the Multi-Region Access Point ARN instead of a bucket name to retrieve the object.

```
suspend fun getObjectFromMrap(s3: S3Client, mrapArn: String, keyName: String): String? {
    val request = GetObjectRequest {
        bucket = mrapArn // Use the ARN instead of the bucket name for object operations.
        key = keyName
    }

    var stringObj: String? = null
    s3.getObject(request) { resp ->
        stringObj = resp.body?.decodeToString()
        if (stringObj != null) {
            println("Successfully read $keyName from $mrapArn")
        }
    }
    return stringObj
}
```

                            const Aws::String &fromBucket,
                            const Aws::Client::ClientConfiguration &clientConfig)
{
    Aws::S3::S3Client client(clientConfig);

    Aws::S3::Model::GetObjectRequest request;
    request.SetBucket(fromBucket);
    request.SetKey(objectKey);

    Aws::S3::Model::GetObjectOutcome outcome =
        client.GetObject(request);

    if (!outcome.IsSuccess()) {
        const Aws::S3::S3Error &err = outcome.GetError();
        std::cerr << "Error: GetObject: " <<
            err.GetExceptionName() << ":" << err.GetMessage() <<
        std::endl;
    }
    else {
        std::cout << "Successfully retrieved '" << objectKey << "' from '" 
            << fromBucket << "." << std::endl;
    }

    return outcome.IsSuccess();
}
```

- For API details, see [GetObject](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

The following example uses the `get-object` command to download an object from Amazon S3:

```
aws s3api get-object --bucket text-content --key dir/my_images.tar.bz2
my_images.tar.bz2
```

Note that the `outfile` parameter is specified without an option name such as `--outfile`. The name of the output file must be the last parameter in the command.

The example below demonstrates the use of `--range` to download a specific byte range from an object. Note the byte ranges needs to be prefixed with "bytes=":

```
aws s3api get-object --bucket text-content --key dir/my_data --range bytes=8888-9999 my_data_range
```

For more information about retrieving objects, see *Getting Objects in the Amazon S3 Developer Guide*.

- For API details, see [GetObject](#) in *AWS CLI Command Reference*.

Download an object from a bucket to a local file.

```
public func downloadFile(bucket: String, key: String, to: String) async throws {
    let fileUrl = URL(fileURLWithPath: to).appendingPathComponent(key)

    let input = GetObjectInput(
        bucket: bucket,
        key: key
    )
    let output = try await client.getObject(input: input)

    // Get the data stream object. Return immediately if there isn't one.
    guard let body = output.body,
        let data = try await body.readData() else {
        return
    }
    try data.write(to: fileUrl)
}
```

Read an object into a Swift Data object.

```
public func readFile(bucket: String, key: String) async throws -> Data {
```

```
let input = GetObjectInput(  
    bucket: bucket,  
    key: key  
)  
let output = try await client.getObject(input: input)  
  
// Get the stream and return its contents in a `Data` object. If  
// there is no stream, return an empty `Data` object instead.  
guard let body = output.body,  
    let data = try await body.readData() else {  
    return "".data(using: .utf8)!  
}  
  
return data  
}
```

Get the policy for an Amazon S3 bucket using an AWS SDK

The following code examples show how to get the policy for an S3 bucket.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
bool AwsDoc::S3::GetBucketPolicy(const Aws::String &bucketName,
                                  const Aws::Client::ClientConfiguration
&clientConfig) {
    Aws::S3::S3Client s3_client(clientConfig);
```

```
Aws::S3::Model::GetBucketPolicyRequest request;
request.SetBucket(bucketName);

Aws::S3::Model::GetBucketPolicyOutcome outcome =
    s3_client.GetBucketPolicy(request);

if (!outcome.IsSuccess()) {
    const Aws::S3::S3Error &err = outcome.GetError();
    std::cerr << "Error: GetBucketPolicy: "
        << err.GetExceptionName() << ":" << err.GetMessage() <<
    std::endl;
}
else {
    Aws::StringStream policy_stream;
    Aws::String line;

    outcome.GetResult().GetPolicy() >> line;
    policy_stream << line;

    std::cout << "Retrieve the policy for bucket '" << bucketName << "' :\n\n"
<<
    policy_stream.str() << std::endl;
}

return outcome.IsSuccess();
}
```

- For API details, see [GetBucketPolicy](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

The following command retrieves the bucket policy for a bucket named my-bucket:

```
aws s3api get-bucket-policy --bucket my-bucket
```

Output:

```
{
```

```
    "Policy": "{\"Version\":\"2008-10-17\", \"Statement\":[{\"Sid\":\"\", \"Effect\": \"Allow\", \"Principal\":\"*\", \"Action\":\"s3:GetObject\", \"Resource\": \"arn:aws:s3:::my-bucket/*\"}, {\"Sid\":\"\", \"Effect\": \"Deny\", \"Principal\": \"*\", \"Action\": \"s3:GetObject\", \"Resource\": \"arn:aws:s3:::my-bucket/secret/*\"}]}"}  
}
```

Get and put a bucket policyThe following example shows how you can download an Amazon S3 bucket policy, make modifications to the file, and then use `put-bucket-policy` to apply the modified bucket policy. To download the bucket policy to a file, you can run:

```
aws s3api get-bucket-policy --bucket mybucket --query Policy --output text > policy.json
```

You can then modify the `policy.json` file as needed. Finally you can apply this modified policy back to the S3 bucket by running:

`policy.json` file as needed. Finally you can apply this modified policy back to the S3 bucket by running:

file as needed. Finally you can apply this modified policy back to the S3 bucket by running:

```
aws s3api put-bucket-policy --bucket mybucket --policy file://policy.json
```

- For API details, see [GetBucketPolicy](#) in *AWS CLI Command Reference*.

```
namespace ListBucketsExample
{
    using System;
    using System.Collections.Generic;
    using System.Threading.Tasks;
    using Amazon.S3;
    using Amazon.S3.Model;

    /// <summary>
    /// This example uses the AWS SDK for .NET to list the Amazon Simple Storage
    /// Service (Amazon S3) buckets belonging to the default account.
    /// </summary>
    public class ListBuckets
    {
        private static IAmazonS3 _s3Client;

        /// <summary>
        /// Get a list of the buckets owned by the default user.
        /// </summary>
        /// <param name="client">An initialized Amazon S3 client object.</param>
        /// <returns>The response from the ListingBuckets call that contains a
        /// list of the buckets owned by the default user.</returns>
        public static async Task<ListBucketsResponse> GetBuckets(IAmazonS3
client)
        {
            return await client.ListBucketsAsync();
        }

        /// <summary>
        /// This method lists the name and creation date for the buckets in
        /// the passed List of S3 buckets.
        /// </summary>
        /// <param name="bucketList">A List of S3 bucket objects.</param>
        public static void DisplayBucketList(List<S3Bucket> bucketList)
        {
            bucketList
                .ForEach(b => Console.WriteLine($"Bucket name: {b.BucketName},
created on: {b.CreationDate}"));
        }

        public static async Task Main()
        {
            // The client uses the AWS Region of the default user.
        }
    }
}
```

```
// If the Region where the buckets were created is different,
// pass the Region to the client constructor. For example:
// _s3Client = new AmazonS3Client(RegionEndpoint.USEast1);
_s3Client = new AmazonS3Client();
var response = await GetBuckets(_s3Client);
DisplayBucketList(response.Buckets);
}
}
}
```

- For API details, see [ListBuckets in AWS SDK for .NET API Reference](#).

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
bool AwsDoc::S3::ListBuckets(const Aws::Client::ClientConfiguration
&clientConfig) {
    Aws::S3::S3Client client(clientConfig);

    auto outcome = client.ListBuckets();

    bool result = true;
    if (!outcome.IsSuccess()) {
        std::cerr << "Failed with error: " << outcome.GetError() << std::endl;
        result = false;
    }
    else {
        std::cout << "Found " << outcome.GetResult().GetBuckets().size() << "
buckets\n";
        for (auto &&b: outcome.GetResult().GetBuckets()) {
            std::cout << b.GetName() << std::endl;
        }
    }
}
```

```
    return result;
}
```

- For API details, see [ListBuckets](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

The following command uses the `list-buckets` command to display the names of all your Amazon S3 buckets (across all regions):

```
aws s3api list-buckets --query "Buckets[].Name"
```

The `query` option filters the output of `list-buckets` down to only the bucket names.

For more information about buckets, see *Working with Amazon S3 Buckets* in the *Amazon S3 Developer Guide*.

- For API details, see [ListBuckets](#) in *AWS CLI Command Reference*.

List in-progress multipart uploads to an Amazon S3 bucket using an AWS SDK

The following code examples show how to list in-progress multipart uploads to an S3 bucket.

CLI

AWS CLI

The following command lists all of the active multipart uploads for a bucket named my-bucket:

```
aws s3api list-multipart-uploads --bucket my-bucket
```

Output:

```
{
    "Uploads": [
        {
            "Initiator": {
                "DisplayName": "username",
                "ID": "arn:aws:iam::0123456789012:user/username"
            },
            "Initiated": "2015-06-02T18:01:30.000Z",
            "UploadId": "dfRtDYU0WWCCcH43C3WFbkR0NycyCpTJJvxu2i5GYkZljF.Yxwh6XG7WfS2vC4to6HiV6Yjlx.cph0gtNBtJ8P3",
            "StorageClass": "STANDARD",
            "Key": "multipart/01",
            "Owner": {
                "DisplayName": "aws-account-name",
                "ID": "100719349fc3b6dcd7c820a124bf7aec408092c3d7b51b38494939801fc248b"
            }
        },
        ],
        "CommonPrefixes": []
}
```

In progress multipart uploads incur storage costs in Amazon S3. Complete or abort an active multipart upload to remove its parts from your account.

- For API details, see [ListMultipartUploads](#) in *AWS CLI Command Reference*.

```
bool AwsDoc::S3::ListObjects(const Aws::String &bucketName,
                             const Aws::Client::ClientConfiguration
                             &clientConfig) {
    Aws::S3::S3Client s3_client(clientConfig);

    Aws::S3::Model::ListObjectsRequest request;
    request.WithBucket(bucketName);

    auto outcome = s3_client.ListObjects(request);
```

```
if (!outcome.IsSuccess()) {
    std::cerr << "Error: ListObjects: " <<
        outcome.GetError().GetMessage() << std::endl;
}
else {
    Aws::Vector<Aws::S3::Model::Object> objects =
        outcome.GetResult().GetContents();

    for (Aws::S3::Model::Object &object: objects) {
        std::cout << object.GetKey() << std::endl;
    }
}

return outcome.IsSuccess();
}
```

- For API details, see [ListObjectsV2](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

The following example uses the `list-objects` command to display the names of all the objects in the specified bucket:

```
aws s3api list-objects --bucket text-content --query 'Contents[].{Key: Key, Size: Size}'
```

The example uses the `--query` argument to filter the output of `list-objects` down to the key value and size for each object

For more information about objects, see *Working with Amazon S3 Objects* in the *Amazon S3 Developer Guide*.

- For API details, see [ListObjectsV2](#) in *AWS CLI Command Reference*.

List all of the objects in your bucket. If there is more than one object, IsTruncated and NextContinuationToken will be used to iterate over the full list.

```
import {
  S3Client,
  // This command supersedes the ListObjectsCommand and is the recommended way to
  // list objects.
  ListObjectsV2Command,
} from "@aws-sdk/client-s3";

const client = new S3Client({});

export const main = async () => {
  const command = new ListObjectsV2Command({
    Bucket: "my-bucket",
    // The default and maximum number of keys returned is 1000. This limits it to
    // one for demonstration purposes.
    MaxKeys: 1,
```

```
});  
  
try {  
    let isTruncated = true;  
  
    console.log("Your bucket contains the following objects:\n");  
    let contents = "";  
  
    while (isTruncated) {  
        const { Contents, IsTruncated, NextContinuationToken } =  
            await client.send(command);  
        const contentsList = Contents.map((c) => ` ${c.Key}`).join("\n");  
        contents += contentsList + "\n";  
        isTruncated = IsTruncated;  
        command.input.ContinuationToken = NextContinuationToken;  
    }  
    console.log(contents);  
} catch (err) {  
    console.error(err);  
}  
};

Restore an archived copy of an object back into an Amazon S3 bucket using an AWS SDK

The following code examples show how to restore an archived copy of an object back into an S3 bucket.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
using System;
using System.Threading.Tasks;
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;

/// <summary>
/// This example shows how to restore an archived object in an Amazon
/// Simple Storage Service (Amazon S3) bucket.
/// </summary>
public class RestoreArchivedObject
{
    public static void Main()
    {
        string bucketName = "doc-example-bucket";
        string objectKey = "archived-object.txt";

        // Specify your bucket region (an example region is shown).
```

```
RegionEndpoint bucketRegion = RegionEndpoint.USWest2;

IAmazonS3 client = new AmazonS3Client(bucketRegion);
RestoreObjectAsync(client, bucketName, objectKey).Wait();
}

/// <summary>
/// This method restores an archived object from an Amazon S3 bucket.
/// </summary>
/// <param name="client">The initialized Amazon S3 client object used to
call
/// RestoreObjectAsync.</param>
/// <param name="bucketName">A string representing the name of the
/// bucket where the object was located before it was archived.</param>
/// <param name="objectKey">A string representing the name of the
/// archived object to restore.</param>
public static async Task RestoreObjectAsync(IAmazonS3 client, string
bucketName, string objectKey)
{
    try
    {
        var restoreRequest = new RestoreObjectRequest
        {
            BucketName = bucketName,
            Key = objectKey,
            Days = 2,
        };
        RestoreObjectResponse response = await
client.RestoreObjectAsync(restoreRequest);

        // Check the status of the restoration.
        await CheckRestorationStatusAsync(client, bucketName, objectKey);
    }
    catch (AmazonS3Exception amazonS3Exception)
    {
        Console.WriteLine($"Error: {amazonS3Exception.Message}");
    }
}

/// <summary>
/// This method retrieves the status of the object's restoration.
/// </summary>
/// <param name="client">The initialized Amazon S3 client object used to
call
```

```
    ///> GetObjectMetadataAsync.</param>
    ///> <param name="bucketName">A string representing the name of the Amazon
    ///> S3 bucket which contains the archived object.</param>

    public static async Task CheckRestorationStatusAsync(IAmazonS3 client,
string bucketName, string objectKey)
{
    GetObjectMetadataRequest metadataRequest = new
GetObjectMetadataRequest()
{
    BucketName = bucketName,
    Key = objectKey,
};

    GetObjectMetadataResponse response = await
client.GetObjectMetadataAsync(metadataRequest);

    var restStatus = response.RestoreInProgress ? "in-progress" :
"finished or failed";
    Console.WriteLine($"Restoration status: {restStatus}");
}
}
```

- For API details, see [RestoreObject](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To create a restore request for an object

The following `restore-object` example restores the specified Amazon S3 Glacier object for the bucket `my-glacier-bucket` for 10 days.

```
aws s3api restore-object \
--bucket my-glacier-bucket \
--key doc1.rtf \
--restore-request Days=10
```

This command produces no output.

- For API details, see [RestoreObject](#) in *AWS CLI Command Reference*.

CLI

AWS CLI

This example grants full control to two AWS users (`user1@example.com` and `user2@example.com`) and read permission to everyone:

```
aws s3api put-bucket-acl --bucket MyBucket --grant-full-control
emailaddress=user1@example.com,emailaddress=user2@example.com --grant-read
uri=http://acs.amazonaws.com/groups/global/AllUsers
```

See <http://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTacl.html> for details on custom ACLs (the s3api ACL commands, such as put-bucket-acl, use the same shorthand argument notation).

- For API details, see [PutBucketAcl](#) in *AWS CLI Command Reference*.

Put the bucket ACL.

```
import {
  PutBucketAclCommand,
  GetBucketAclCommand,
  S3Client,
} from "@aws-sdk/client-s3";

const client = new S3Client({});

// Most Amazon S3 use cases don't require the use of access control lists (ACLs).
// We recommend that you disable ACLs, except in unusual circumstances where
// you need to control access for each object individually.
// Consider a policy instead. For more information see https://
docs.aws.amazon.com/AmazonS3/latest/userguide/bucket-policies.html.
export const main = async () => {
```

```
// Grant a user READ access to a bucket.
const command = new PutBucketAclCommand({
  Bucket: "test-bucket",
  AccessControlPolicy: {
    Grants: [
      {
        Grantee: {
          // The canonical ID of the user. This ID is an obfuscated form of
          // your AWS account number.
          // It's unique to Amazon S3 and can't be found elsewhere.
          // For more information, see https://docs.aws.amazon.com/AmazonS3/
          latest/userguide/finding-canonical-user-id.html.
          ID: "canonical-id-1",

CLI

AWS CLI

The following command grants full control to two AWS users (`user1@example.com` and `user2@example.com`) and read permission to everyone:

```
aws s3api put-object-acl --bucket MyBucket --key file.txt --grant-full-control
emailaddress=user1@example.com,emailaddress=user2@example.com --grant-read
uri=http://acs.amazonaws.com/groups/global/AllUsers
```

See <http://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTacl.html> for details on custom ACLs (the `s3api` ACL commands, such as `put-object-acl`, use the same shorthand argument notation).

- For API details, see [PutObjectAcl](#) in *AWS CLI Command Reference*.

        << bucketName << "." << std::endl;
}

return outcome.IsSuccess();
}
```

- For API details, see [PutBucketWebsite](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

The applies a static website configuration to a bucket named my-bucket:

```
aws s3api put-bucket-website --bucket my-bucket --website-configuration file://
website.json
```

The file `website.json` is a JSON document in the current folder that specifies index and error pages for the website:

```
{
    "IndexDocument": {
        "Suffix": "index.html"
    },
    "ErrorDocument": {
        "Key": "error.html"
    }
}
```

- For API details, see [PutBucketWebsite](#) in *AWS CLI Command Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Upload a single part of a multipart upload using an AWS SDK

The following code examples show how to upload a single part of a multipart upload.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Perform a multipart upload](#)
- [Use checksums](#)

CLI

AWS CLI

The following command uploads the first part in a multipart upload initiated with the `create-multipart-upload` command:

```
aws s3api upload-part --bucket my-bucket --key 'multipart/01' --part-number 1 --
body part01 --upload-id
"dfRtDYU0WWCCcH43C3WFbkRONycyCpTJJvxu2i5GYkZlxF.Yxwh6XG7WfS2vC4to6HiV6Yjlx.cph0gtNBtJ8P3"
```

The body option takes the name or path of a local file for upload (do not use the file:// prefix). The minimum part size is 5 MB. Upload ID is returned by `create-multipart-upload` and can also be retrieved with `list-multipart-uploads`. Bucket and key are specified when you create the multipart upload.

Output:

```
{  
    "ETag": "\"e868e0f4719e394144ef36531ee6824c\""  
}
```

Save the ETag value of each part for later. They are required to complete the multipart upload.

- For API details, see [UploadPart in AWS CLI Command Reference](#).

Rust

SDK for Rust

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
let upload_part_res = client  
    .upload_part()  
    .key(&key)  
    .bucket(&bucket_name)  
    .upload_id(upload_id)  
    .body(stream)  
    .part_number(part_number)  
    .send()  
    .await?;  
upload_parts.push(  
    CompletedPart::builder()  
        .e_tag(upload_part_res.e_tag.unwrap_or_default())  
        .part_number(part_number)  
        .build(),  
);
```

```
let completed_multipart_upload: CompletedMultipartUpload =
CompletedMultipartUpload::builder()
    .set_parts(Some(upload_parts))
    .build();
```

            outcome.GetError().GetMessage() << std::endl;
```

```
    }
    else {
        std::cout << "Added object '" << fileName << "' to bucket ''"
              << bucketName << "'.";
    }

    return outcome.IsSuccess();
}
```

- For API details, see [PutObject](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

The following example uses the put-object command to upload an object to Amazon S3:

```
aws s3api put-object --bucket text-content --key dir-1/my_images.tar.bz2 --body
my_images.tar.bz2
```

The following example shows an upload of a video file (The video file is specified using Windows file system syntax.):

```
aws s3api put-object --bucket text-content --key dir-1/big-video-file.mp4 --body
e:\media\videos\f-sharp-3-data-services.mp4
```

For more information about uploading objects, see *Uploading Objects in the Amazon S3 Developer Guide*.

- For API details, see [PutObject](#) in *AWS CLI Command Reference*.

Scenarios for Amazon S3 using AWS SDKs

The following code examples show you how to implement common scenarios in Amazon S3 with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Amazon S3. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- [Create a presigned URL for Amazon S3 using an AWS SDK](#)

- [A web page that lists Amazon S3 objects using an AWS SDK](#)
- [Get started with Amazon S3 buckets and objects using an AWS SDK](#)
- [Get started with encryption for Amazon S3 objects using an AWS SDK](#)
- [Get started with tags for Amazon S3 objects using an AWS SDK](#)
- [Manage access control lists \(ACLs\) for Amazon S3 buckets using an AWS SDK](#)
- [Manage versioned Amazon S3 objects in batches with a Lambda function using an AWS SDK](#)
- [Parse Amazon S3 URIs using an AWS SDK](#)
- [Perform a multipart copy of an Amazon S3 object using an AWS SDK](#)
- [Perform a multipart upload to an Amazon S3 object using an AWS SDK](#)
- [Upload or download large files to and from Amazon S3 using an AWS SDK](#)
- [Upload a stream of unknown size to an Amazon S3 object using an AWS SDK](#)
- [Use checksums to work with an Amazon S3 object using an AWS SDK](#)
- [Work with Amazon S3 versioned objects using an AWS SDK](#)

Create a presigned URL for Amazon S3 using an AWS SDK

The following code examples show how to create a presigned URL for Amazon S3 and upload an object.

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Generate a presigned URL that can perform an Amazon S3 action for a limited time.

```
using System;
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
```

```
public class GenPresignedUrl
{
    public static void Main()
    {
        const string bucketName = "doc-example-bucket";
        const string objectKey = "sample.txt";

        // Specify how long the presigned URL lasts, in hours
        const double timeoutDuration = 12;

        // Specify the AWS Region of your Amazon S3 bucket. If it is
        // different from the Region defined for the default user,
        // pass the Region to the constructor for the client. For
        // example: new AmazonS3Client(RegionEndpoint.USEast1);

        // If using the Region us-east-1, and server-side encryption with AWS
        // KMS, you must specify Signature Version 4.
        // Region us-east-1 defaults to Signature Version 2 unless explicitly
        // set to Version 4 as shown below.
        // For more details, see https://docs.aws.amazon.com/AmazonS3/latest/
        // userguide/UsingAWSSDK.html#specify-signature-version
        // and https://docs.aws.amazon.com/sdkfornet/v3/apidocs/items/Amazon/
        // TAWSConfigsS3.html
        AWSConfigsS3.UseSignatureVersion4 = true;
        IAmazonS3 s3Client = new AmazonS3Client(RegionEndpoint.USEast1);

        string urlString = GeneratePresignedURL(s3Client, bucketName,
        objectKey, timeoutDuration);
        Console.WriteLine($"The generated URL is: {urlString}.");
    }

    /// <summary>
    /// Generate a presigned URL that can be used to access the file named
    /// in the objectKey parameter for the amount of time specified in the
    /// duration parameter.
    /// </summary>
    /// <param name="client">An initialized S3 client object used to call
    /// the GetPresignedUrl method.</param>
    /// <param name="bucketName">The name of the S3 bucket containing the
    /// object for which to create the presigned URL.</param>
    /// <param name="objectKey">The name of the object to access with the
    /// presigned URL.</param>
    /// <param name="duration">The length of time for which the presigned
    /// URL will be valid.</param>
```

```
/// <returns>A string representing the generated presigned URL.</returns>
public static string GeneratePresignedURL(IAmazonS3 client, string
bucketName, string objectKey, double duration)
{
    string urlString = string.Empty;
    try
    {
        var request = new GetPreSignedUrlRequest()
        {
            BucketName = bucketName,
            Key = objectKey,
            Expires = DateTime.UtcNow.AddHours(duration),
        };
        urlString = client.GetPreSignedURL(request);
    }
    catch (AmazonS3Exception ex)
    {
        Console.WriteLine($"Error:{ex.Message}");
    }

    return urlString;
}
}
```

Generate a presigned URL and perform an upload using that URL.

```
using System;
using System.IO;
using System.Net.Http;
using System.Threading.Tasks;
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;

/// <summary>
/// This example shows how to upload an object to an Amazon Simple Storage
/// Service (Amazon S3) bucket using a presigned URL. The code first
/// creates a presigned URL and then uses it to upload an object to an
/// Amazon S3 bucket using that URL.
/// </summary>
public class UploadUsingPresignedURL
```

```
{  
    private static HttpClient httpClient = new HttpClient();  
  
    public static async Task Main()  
    {  
        string bucketName = "doc-example-bucket";  
        string keyName = "samplefile.txt";  
        string filePath = $"source\\{keyName}";  
  
        // Specify how long the signed URL will be valid in hours.  
        double timeoutDuration = 12;

Create functions that wrap S3 presigning actions.

```
// Presigner encapsulates the Amazon Simple Storage Service (Amazon S3) presign actions
// used in the examples.
// It contains PresignClient, a client that is used to presign requests to Amazon S3.
// Presigned requests contain temporary credentials and can be made from any HTTP client.
type Presigner struct {
    PresignClient *s3.PresignClient
}

// GetObject makes a presigned request that can be used to get an object from a bucket.
// The presigned request is valid for the specified number of seconds.
func (presigner Presigner) GetObject(
```

```
bucketName string, objectKey string, lifetimeSecs int64)
(*v4.PresignedHTTPRequest, error) {
request, err := presigner.PresignClient.PresignGetObject(context.TODO(),
&s3.GetObjectInput{
Bucket: aws.String(bucketName),
Key:    aws.String(objectKey),
}, func(opts *s3.PresignOptions) {
opts.Expires = time.Duration(lifetimeSecs * int64(time.Second))
})
if err != nil {
log.Printf("Couldn't get a presigned request to get %v:%v. Here's why: %v\n",
bucketName, objectKey, err)
}
return request, err
}

// PutObject makes a presigned request that can be used to put an object in a
// bucket.
// The presigned request is valid for the specified number of seconds.
func (presigner Presigner) PutObject(
bucketName string, objectKey string, lifetimeSecs int64)
(*v4.PresignedHTTPRequest, error) {
request, err := presigner.PresignClient.PresignPutObject(context.TODO(),
&s3.PutObjectInput{
Bucket: aws.String(bucketName),
Key:    aws.String(objectKey),
}, func(opts *s3.PresignOptions) {
opts.Expires = time.Duration(lifetimeSecs * int64(time.Second))
})
if err != nil {
log.Printf("Couldn't get a presigned request to put %v:%v. Here's why: %v\n",
bucketName, objectKey, err)
}
return request, err
}

// DeleteObject makes a presigned request that can be used to delete an object
// from a bucket.
func (presigner Presigner) DeleteObject(bucketName string, objectKey string)
(*v4.PresignedHTTPRequest, error) {
```

```
request, err := presigner.PresignClient.PresignDeleteObject(context.TODO(),
&s3.DeleteObjectInput{
    Bucket: aws.String(bucketName),
    Key:    aws.String(objectKey),
})
if err != nil {

%v\n", objectKey, err)
}
return request, err
}
```

Run an interactive example that generates and uses presigned URLs to upload, download, and delete an S3 object.

```
// RunPresigningScenario is an interactive example that shows you how to get
presigned
// HTTP requests that you can use to move data into and out of Amazon Simple
Storage
// Service (Amazon S3). The presigned requests contain temporary credentials and
can
// be used by an HTTP client.
//
// 1. Get a presigned request to put an object in a bucket.
// 2. Use the net/http package to use the presigned request to upload a local
file to the bucket.
// 3. Get a presigned request to get an object from a bucket.
// 4. Use the net/http package to use the presigned request to download the
object to a local file.
// 5. Get a presigned request to delete an object from a bucket.
// 6. Use the net/http package to use the presigned request to delete the object.
//
// This example creates an Amazon S3 presign client from the specified sdkConfig
so that
// you can replace it with a mocked or stubbed config for unit testing.
//
// It uses a questioner from the `demotools` package to get input during the
example.
// This package can be found in the ..\..\demotools folder of this repo.
//
```

```
// It uses an IHttpRequester interface to abstract HTTP requests so they can be
// mocked
// during testing.

        return presignedRequest.url().toExternalForm();
    }
}
```

Download the object by using any one of the following three approaches.

Use JDK HttpURLConnection (since v1.1) class to do the download.

```
/* Use the JDK HttpURLConnection (since v1.1) class to do the download. */
public byte[] useHttpURLConnectionToGet(String presignedUrlString) {
    ByteArrayOutputStream byteArrayOutputStream = new
ByteArrayOutputStream(); // Capture the response body to a byte array.

    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpURLConnection connection = (HttpURLConnection)
presignedUrl.openConnection();
        connection.setRequestMethod("GET");
        // Download the result of executing the request.
        try (InputStream content = connection.getInputStream()) {
            IoUtils.copy(content, byteArrayOutputStream);
        }
        logger.info("HTTP response code is " + connection.getResponseCode());
    } catch (S3Exception | IOException e) {
```

```
        logger.error(e.getMessage(), e);
    }
    return byteArrayOutputStream.toByteArray();
}
```

Use JDK HttpClient (since v11) class to do the download.

```
/* Use the JDK HttpClient (since v11) class to do the download. */
public byte[] useHttpClientToGet(String presignedUrlString) {
    ByteArrayOutputStream byteArrayOutputStream = new
ByteArrayOutputStream(); // Capture the response body to a byte array.

    HttpRequest.Builder requestBuilder = HttpRequest.newBuilder();
    HttpClient httpClient = HttpClient.newHttpClient();
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpResponse<InputStream> response = httpClient.send(requestBuilder
            .uri(presignedUrl.toURI())
            .GET()
            .build(),
        HttpResponse.BodyHandlers.ofInputStream());

        IoUtils.copy(response.body(), byteArrayOutputStream);

        logger.info("HTTP response code is " + response.statusCode());
    } catch (URISyntaxException | InterruptedException | IOException e) {
        logger.error(e.getMessage(), e);
    }
    return byteArrayOutputStream.toByteArray();
}
```

Use the AWS SDK for Java SdkHttpClient class to do the download.

```
/* Use the AWS SDK for Java SdkHttpClient class to do the download. */
public byte[] useSdkHttpClientToPut(String presignedUrlString) {

    ByteArrayOutputStream byteArrayOutputStream = new
ByteArrayOutputStream(); // Capture the response body to a byte array.
    try {
        URL presignedUrl = new URL(presignedUrlString);
```

```
SdkHttpRequest request = SdkHttpRequest.builder()
    .method(SdkHttpMethod.GET)
    .uri(presignedUrl.toURI())
    .build();

HttpExecuteRequest executeRequest = HttpExecuteRequest.builder()
    .request(request)
    .build();

try (SdkHttpClient sdkHttpClient = ApacheHttpClient.create()) {
    HttpExecuteResponse response =
        sdkHttpClient.prepareRequest(executeRequest).call();
    response.responseBody().ifPresentOrElse(
        abortableInputStream -> {
            try {
                IoUtils.copy(abortableInputStream,
byteArrayOutputStream);
            } catch (IOException e) {
                throw new RuntimeException(e);
            }
        },
        () -> logger.error("No response body."));
    logger.info("HTTP Response code is {}",

response.httpResponse().statusCode());
}
} catch (URISyntaxException | IOException e) {
    logger.error(e.getMessage(), e);
}
return byteArrayOutputStream.toByteArray();
}
```

return presignedRequest.url().toExternalForm();
}
```

Upload a file object by using any one of the following three approaches.

Use the JDK HttpURLConnection (since v1.1) class to do the upload.

```
/* Use the JDK HttpURLConnection (since v1.1) class to do the upload. */
public void useHttpURLConnectionToPut(String presignedUrlString, File
fileToPut, Map<String, String> metadata) {
    logger.info("Begin [{}] upload", fileToPut.toString());
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpURLConnection connection = (HttpURLConnection)
presignedUrl.openConnection();
        connection.setDoOutput(true);
        metadata.forEach((k, v) -> connection.setRequestProperty("x-amz-
meta-" + k, v));
        connection.setRequestMethod("PUT");
        OutputStream out = connection.getOutputStream();

        try (RandomAccessFile file = new RandomAccessFile(fileToPut, "r");
            FileChannel inChannel = file.getChannel()) {
            ByteBuffer buffer = ByteBuffer.allocate(8192); //Buffer size is
8k

            while (inChannel.read(buffer) > 0) {
```

```
        buffer.flip();
        for (int i = 0; i < buffer.limit(); i++) {
            out.write(buffer.get());
        }
        buffer.clear();
    }

} catch (IOException e) {
    logger.error(e.getMessage(), e);
}

out.close();
connection.getResponseCode();
logger.info("HTTP response code is " + connection.getResponseCode());

} catch (S3Exception | IOException e) {
    logger.error(e.getMessage(), e);
}
}
```

Use the JDK HttpClient (since v11) class to do the upload.

```
/* Use the JDK HttpClient (since v11) class to do the upload. */
public void useHttpClientToPut(String presignedUrlString, File fileToPut,
Map<String, String> metadata) {
    logger.info("Begin [{}] upload", fileToPut.toString());

    HttpRequest.Builder requestBuilder = HttpRequest.newBuilder();
    metadata.forEach((k, v) -> requestBuilder.header("x-amz-meta-" + k, v));

    HttpClient httpClient = HttpClient.newHttpClient();
    try {
        final HttpResponse<Void> response = httpClient.send(requestBuilder
            .uri(new URL(presignedUrlString).toURI())

.PUT(HttpRequest.BodyPublishers.ofFile(Path.of(fileToPut.toURI())))
            .build(),
        HttpResponse.BodyHandlers.discard());
    }

    logger.info("HTTP response code is " + response.statusCode());

} catch (URISyntaxException | InterruptedException | IOException e) {
    logger.error(e.getMessage(), e);
}
```

```
    }  
}
```

Use the AWS for Java V2 SdkHttpClient class to do the upload.

```
/* Use the AWS SDK for Java V2 SdkHttpClient class to do the upload. */  
public void useSdkHttpClientToPut(String presignedUrlString, File fileToPut,  
Map<String, String> metadata) {  
    logger.info("Begin [{}] upload", fileToPut.toString());  
  
    try {  
        URL presignedUrl = new URL(presignedUrlString);

Create a presigned URL to upload an object to a bucket.

```
import https from "https";
import { PutObjectCommand, S3Client } from "@aws-sdk/client-s3";
import { fromIni } from "@aws-sdk/credential-providers";
import { HttpRequest } from "@smithy/protocol-http";
import {
  getSignedUrl,
  S3RequestPresigner,
} from "@aws-sdk/s3-request-presigner";
import { parseUrl } from "@smithy/url-parser";
import { formatUrl } from "@aws-sdk/util-format-url";
import { Hash } from "@smithy/hash-node";

const createPresignedUrlWithoutClient = async ({ region, bucket, key }) => {
  const url = parseUrl(`https://${bucket}.s3.${region}.amazonaws.com/${key}`);
  const presigner = new S3RequestPresigner({
    credentials: fromIni(),
    region,
    sha256: Hash.bind(null, "sha256"),
  });

  const signedUrlObject = await presigner.presign(
    new HttpRequest({ ...url, method: "PUT" }),
  );
  return formatUrl(signedUrlObject);
};

const createPresignedUrlWithClient = ({ region, bucket, key }) => {
  const client = new S3Client({ region });
  const command = new PutObjectCommand({ Bucket: bucket, Key: key });
  return getSignedUrl(client, command, { expiresIn: 3600 });
};
```

```
function put(url, data) {
    return new Promise((resolve, reject) => {
        const req = https.request(
            url,
            { method: "PUT", headers: { "Content-Length": new Blob([data]).size } },
            (res) => {
                let responseBody = "";
                res.on("data", (chunk) => {
                    responseBody += chunk;
                });
                res.on("end", () => {
                    resolve(responseBody);
                });
            },
        );
        req.on("error", (err) => {
            reject(err);
        });
        req.write(data);
        req.end();
    });
}

export const main = async () => {
    const REGION = "us-east-1";
    const BUCKET = "example_bucket";
    const KEY = "example_file.txt";

    // There are two ways to generate a presigned URL.
    // 1. Use createPresignedUrl without the S3 client.
    // 2. Use getSignedUrl in conjunction with the S3 client and GetObjectCommand.
    try {
        const noClientUrl = await createPresignedUrlWithoutClient({
            region: REGION,
            bucket: BUCKET,
            key: KEY,
        });

        const clientUrl = await createPresignedUrlWithClient({
            region: REGION,
            bucket: BUCKET,
            key: KEY,
        });
    }
}
```

```
// After you get the presigned URL, you can provide your own file
// data. Refer to put() above.
console.log("Calling PUT using presigned URL without client");

Create a GetObject presigned request and use the URL to download an object.

```
suspend fun getObjectPresigned(s3: S3Client, bucketName: String, keyName: String): String {
    // Create a GetObjectRequest.
    val unsignedRequest = GetObjectRequest {
        bucket = bucketName
        key = keyName
    }

    // Presign the GetObject request.
    val presignedRequest = s3.presignGetObject(unsignedRequest, 24.hours)

    // Use the URL from the presigned HttpRequest in a subsequent HTTP GET
    // request to retrieve the object.
    val objectContents = URL(presignedRequest.url.toString()).readText()

    return objectContents
}
```

Create a GetObject presigned request with advanced options.

```
suspend fun getObjectPresignedMoreOptions(s3: S3Client, bucketName: String,
keyName: String): HttpRequest {
    // Create a GetObjectRequest.
    val unsignedRequest = GetObjectRequest {
        bucket = bucketName
        key = keyName
    }

    // Presign the GetObject request.
    val presignedRequest = s3.presignGetObject(unsignedRequest, 24.hours)
```

```
    val presignedRequest = s3.presignGetObject(unsignedRequest, signer =
CrtAwsSigner) {
    signingDate = Instant.now() + 12.hours // Presigned request can be used
12 hours from now.
    algorithm = AwsSigningAlgorithm.SIGV4_ASYMMETRIC
    signatureType = AwsSignatureType.HTTP_REQUEST_VIA_QUERY_PARAMS
    expiresAfter = 8.hours // Presigned request expires 8 hours later.
}
return presignedRequest
}
```

Create a PutObject presigned request and use it to upload an object.

```
suspend fun putObjectPresigned(s3: S3Client, bucketName: String, keyName: String,
content: String) {
// Create a PutObjectRequest.
val unsignedRequest = PutObjectRequest {
    bucket = bucketName
    key = keyName
}

// Presign the request.
val presignedRequest = s3.presignPutObject(unsignedRequest, 24.hours)

// Use the URL and any headers from the presigned HttpRequest in a subsequent
HTTP PUT request to retrieve the object.
// Create a PUT request using the OkHttpClient API.
val putRequest = Request
    .Builder()
    .url(presignedRequest.url.toString())
    .apply {
        presignedRequest.headers.forEach { key, values ->
            header(key, values.joinToString(", "))
        }
    }
    .put(content.toRequestBody())
    .build()

val response = OkHttpClient().newCall(putRequest).execute()
assert(response.isSuccessful)
}
```

The following code is the relevant React component that makes calls to the AWS SDK. A runnable version of the application containing this component can be found at the preceding GitHub link.

```
import { useEffect, useState } from "react";
import {
  ListObjectsCommand,
  ListObjectsCommandOutput,
  S3Client,
} from "@aws-sdk/client-s3";
import { fromCognitoIdentityPool } from "@aws-sdk/credential-providers";
import "./App.css";

function App() {
  const [objects, setObjects] = useState<
    Required<ListObjectsCommandOutput>["Contents"]
  >([]);
  useEffect(() => {
    const client = new S3Client({
      region: "us-east-1",
      // Unless you have a public bucket, you'll need access to a private bucket.
      // One way to do this is to create an Amazon Cognito identity pool, attach
      // a role to the pool,
```

```
// and grant the role access to the 's3:GetObject' action.  
//  
// You'll also need to configure the CORS settings on the bucket to allow  
traffic from  
// this example site. Here's an example configuration that allows all  
origins. Don't  
// do this in production.  
//[  
// {  
//   "AllowedHeaders": ["*"],  
//   "AllowedMethods": ["GET"],  
//   "AllowedOrigins": ["*"],  
//   "ExposeHeaders": [],  
// },  
//]  
//  
credentials: fromCognitoIdentityPool({  
  clientConfig: { region: "us-east-1" },  
  identityPoolId: "<YOUR_IDENTITY_POOL_ID>",  
},  
});  
const command = new ListObjectsCommand({ Bucket: "bucket-name" });  
client.send(command).then(({ Contents }) => setObjects(Contents || []));  
, []);  
  
return (  
  <div className="App">  
    {objects.map((o) => (  
      <div key={o.ETag}>{o.Key}</div>  
    ))}  
  </div>  
>  
);  
}  
  
export default App;
```

Get started with Amazon S3 buckets and objects using an AWS SDK

The following code examples show how to:

- Create a bucket and upload a file to it.
- Download an object from a bucket.
- Copy an object to a subfolder in a bucket.
- List the objects in a bucket.
- Delete the bucket objects and the bucket.

Run an interactive scenario that shows you how work with S3 buckets and objects.

```
// RunGetStartedScenario is an interactive example that shows you how to use
// Amazon
// Simple Storage Service (Amazon S3) to create an S3 bucket and use it to store
// objects.
//
// 1. Create a bucket.
// 2. Upload a local file to the bucket.
// 3. Upload a large object to the bucket by using an upload manager.
// 4. Download an object to a local file.
// 5. Download a large object by using a download manager.
// 6. Copy an object to a different folder in the bucket.
// 7. List objects in the bucket.
// 8. Delete all objects in the bucket.
// 9. Delete the bucket.
//
// This example creates an Amazon S3 service client from the specified sdkConfig
// so that
// you can replace it with a mocked or stubbed config for unit testing.
//
// It uses a questioner from the `demotools` package to get input during the
// example.
// This package can be found in the ..\..\demotools folder of this repo.

Java

SDK for Java 2.x

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**  
 * Before running this Java V2 code example, set up your development  
 * environment, including your credentials.  
 *  
 * For more information, see the following documentation topic:  
 *  
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html  
 *  
 * This Java code example performs the following tasks:  
 *  
 * 1. Creates an Amazon S3 bucket.  
 * 2. Uploads an object to the bucket.  
 * 3. Downloads the object to another local file.  
 * 4. Uploads an object using multipart upload.  
 * 5. List all objects located in the Amazon S3 bucket.  
 * 6. Copies the object to another Amazon S3 bucket.
```

```
* 7. Deletes the object from the Amazon S3 bucket.  
* 8. Deletes the Amazon S3 bucket.  
*/

JavaScript

SDK for JavaScript (v3)

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

First, import all the necessary modules.

```
// Used to check if currently running file is this file.
import { fileURLToPath } from "url";
```

```
import { readdirSync, readFileSync, writeFileSync } from "fs";

// Local helper utils.
import { dirnameFromMetaUrl } from "@aws-sdk-examples/libs/utils/util-fs.js";
import { Prompter } from "@aws-sdk-examples/libs/prompter.js";
import { wrapText } from "@aws-sdk-examples/libs/utils/util-string.js";

import {
  S3Client,
  CreateBucketCommand,
  PutObjectCommand,
  ListObjectsCommand,
  CopyObjectCommand,
  GetObjectCommand,
  DeleteObjectsCommand,
  DeleteBucketCommand,
} from "@aws-sdk/client-s3";
```

The preceding imports reference some helper utilities. These utilities are local to the GitHub repository linked at the start of this section. For your reference, see the following implementations of those utilities.

```
export const dirnameFromMetaUrl = (metaUrl) =>
  fileURLToPath(new URL(".", metaUrl));

import { select, input, confirm, checkbox } from "@inquirer/prompts";

export class Prompter {
  /**
   * @param {{ message: string, choices: { name: string, value: string }[] }} options
   */
  select(options) {
    return select(options);
  }

  /**
   * @param {{ message: string }} options
   */
  input(options) {
    return input(options);
  }
}
```

```
/**  
 * @param {string} prompt  
 */  
checkContinue = async (prompt = "") => {  
    const prefix = prompt && prompt + " ";  
    let ok = await this.confirm({  
        message: `${prefix}Continue?`,  
    });  
    if (!ok) throw new Error("Exiting...");  
};  
  
/**  
 * @param {{ message: string }} options  
 */  
confirm(options) {  
    return confirm(options);  
}  
  
/**  
 * @param {{ message: string, choices: { name: string, value: string }[] }} options  
 */  
checkbox(options) {  
    return checkbox(options);  
}  
}  
  
export const wrapText = (text, char = "=") => {  
    const rule = char.repeat(80);  
    return `${rule}\n${text}\n${rule}\n`;  
};
```

Objects in S3 are stored in 'buckets'. Let's define a function for creating a new bucket.

```
export const createBucket = async () => {  
    const bucketName = await prompter.input({  
        message: "Enter a bucket name. Bucket names must be globally unique:",  
    });  
    const command = new CreateBucketCommand({ Bucket: bucketName });  
    await s3Client.send(command);  
    console.log("Bucket created successfully.\n");
```

```
    return bucketName;  
};
```

Buckets contain 'objects'. This function uploads the contents of a directory to your bucket as objects.

```
export const uploadFilesToBucket = async ({ bucketName, folderPath }) => {  
  console.log(`Uploading files from ${folderPath}\n`);  
  const keys =.readdirSync(folderPath);  
  const files = keys.map((key) => {  
    const filePath = `${folderPath}/${key}`;  
    const fileContent = readFileSync(filePath);  
    return {  
      Key: key,  
      Body: fileContent,  
    };  
  });  
  
  for (let file of files) {  
    await s3Client.send(  
      new PutObjectCommand({  
        Bucket: bucketName,  
        Body: file.Body,  
        Key: file.Key,  
      }),  
    );  
    console.log(`${file.Key} uploaded successfully.`);  
  }  
};
```

After uploading objects, check to confirm that they were uploaded correctly. You can use `ListObjects` for that. You'll be using the 'Key' property, but there are other useful properties in the response also.

```
export const listFilesInBucket = async ({ bucketName }) => {  
  const command = new ListObjectsCommand({ Bucket: bucketName });  
  const { Contents } = await s3Client.send(command);  
  const contentsList = Contents.map((c) => ` • ${c.Key}`).join("\n");  
  console.log("\nHere's a list of files in the bucket:");  
  console.log(contentsList + "\n");
```

```
};
```

Sometimes you might want to copy an object from one bucket to another. Use the `CopyObject` command for that.

```
export const copyFileFromBucket = async ({ destinationBucket }) => {
  const proceed = await prompter.confirm({
    message: "Would you like to copy an object from another bucket?",
  });

  if (!proceed) {
    return;
  } else {
    const copy = async () => {
      try {
        const sourceBucket = await prompter.input({
          message: "Enter source bucket name:",
        });
        const sourceKey = await prompter.input({
          message: "Enter source key:",
        });
        const destinationKey = await prompter.input({
          message: "Enter destination key:",
        });

        const command = new CopyObjectCommand({
          Bucket: destinationBucket,
          CopySource: `${sourceBucket}/${sourceKey}`,
          Key: destinationKey,
        });
        await s3Client.send(command);
        await copyFileFromBucket({ destinationBucket });
      } catch (err) {
        console.error(`Copy error.`);
        console.error(err);
        const retryAnswer = await prompter.confirm({ message: "Try again?" });
        if (retryAnswer) {
          await copy();
        }
      }
    };
    await copy();
  }
};
```

```
};
```

There's no SDK method for getting multiple objects from a bucket. Instead, you'll create a list of objects to download and iterate over them.

```
export const downloadFilesFromBucket = async ({ bucketName }) => {
  const { Contents } = await s3Client.send(
    new ListObjectsCommand({ Bucket: bucketName }),
  );
  const path = await prompter.input({
    message: "Enter destination path for files:",
  });

  for (let content of Contents) {
    const obj = await s3Client.send(
      new GetObjectCommand({ Bucket: bucketName, Key: content.Key }),
    );
    writeFileSync(
      `${path}/${content.Key}`,
      await obj.Body.transformToByteArray(),
    );
  }
  console.log("Files downloaded successfully.\n");
};
```

It's time to clean up your resources. A bucket must be empty before it can be deleted. These two functions empty and delete the bucket.

```
export const emptyBucket = async ({ bucketName }) => {
  const listObjectsCommand = new ListObjectsCommand({ Bucket: bucketName });
  const { Contents } = await s3Client.send(listObjectsCommand);
  const keys = Contents.map((c) => c.Key);

  const deleteObjectsCommand = new DeleteObjectsCommand({
    Bucket: bucketName,

Swift

SDK for Swift

 **Note**

This is prerelease documentation for an SDK in preview release. It is subject to change.

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

A Swift class that handles calls to the SDK for Swift.

```
import Foundation
import AWSS3
import ClientRuntime
import AWSClientRuntime

/// A class containing all the code that interacts with the AWS SDK for Swift.
public class ServiceHandler {
    let client: S3Client

    /// Initialize and return a new ``ServiceHandler`` object, which is used to
    drive the AWS calls
    /// used for the example.
    ///
    /// - Returns: A new ``ServiceHandler`` object, ready to be called to
    ///           execute AWS operations.
    public init() async {
        do {
            client = try S3Client(region: "us-east-2")
        } catch {
            print("ERROR: ", dump(error, name: "Initializing S3 client"))
            exit(1)
        }
    }
}
```

```
        }

    }

    /// Create a new user given the specified name.
    ///
    /// - Parameters:
    ///   - name: Name of the bucket to create.
    /// Throws an exception if an error occurs.

Manage versioned Amazon S3 objects in batches with a Lambda function using an AWS SDK

The following code example shows how to manage versioned S3 objects in batches with a Lambda function.

Python

SDK for Python (Boto3)

Shows how to manipulate Amazon Simple Storage Service (Amazon S3) versioned objects in batches by creating jobs that call AWS Lambda functions to perform processing. This example creates a version-enabled bucket, uploads the stanzas from the poem *You Are Old, Father William* by Lewis Carroll, and uses Amazon S3 batch jobs to twist the poem in various ways.

Learn how to:

- Create Lambda functions that operate on versioned objects.
- Create a manifest of objects to update.
- Create batch jobs that invoke Lambda functions to update objects.
- Delete Lambda functions.
- Empty and delete a versioned bucket.

This example is best viewed on GitHub. For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon S3

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Parse Amazon S3 URIs using an AWS SDK

The following code example shows how to parse Amazon S3 URIs to extract important components like the bucket name and object key.

Java

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Parse an Amazon S3 URI by using the [S3Uri](#) class.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.S3Uri;
import software.amazon.awssdk.services.s3.S3Utilities;

import java.net.URI;
import java.util.List;
import java.util.Map;

/**
 *
 * @param s3Client      - An S3Client through which you acquire an S3Uri
 * instance.
 * @param s3ObjectUrl   - A complex URL (String) that is used to demonstrate
 * S3Uri
 *                      capabilities.
 */
public static void parseS3UriExample(S3Client s3Client, String s3ObjectUrl) {
    logger.info(s3ObjectUrl);
    // Console output:
    // 'https://s3.us-west-1.amazonaws.com/myBucket/resources/doc.txt?
versionId=abc123&partNumber=77&partNumber=88'.

    // Create an S3Utilities object using the configuration of the s3Client.
    S3Utilities s3Utilities = s3Client.utilities();

    // From a String URL create a URI object to pass to the parseUri()
    method.
    URI uri = URI.create(s3ObjectUrl);
```

```
S3Uri s3Uri = s3Utilities.parseUri(uri);

// If the URI contains no value for the Region, bucket or key, the SDK
returns
// an empty Optional.
// The SDK returns decoded URI values.

Region region = s3Uri.region().orElse(null);
log("region", region);
// Console output: 'region: us-west-1'.

String bucket = s3Uri.bucket().orElse(null);

Perform a multipart upload to an Amazon S3 object using an AWS SDK

The following code example shows how to perform a multipart upload to an Amazon S3 object.

Java

SDK for Java 2.x

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

The code examples use the following imports.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.exception.SdkException;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.CompletedMultipartUpload;
import software.amazon.awssdk.services.s3.model.CompletedPart;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadResponse;
import software.amazon.awssdk.services.s3.model.UploadPartRequest;
import software.amazon.awssdk.services.s3.model.UploadPartResponse;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.FileUpload;
import software.amazon.awssdk.transfer.s3.model.UploadFileRequest;
```

```
import java.io.IOException;
import java.io.RandomAccessFile;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.ByteBuffer;
import java.nio.file.Paths;
import java.util.ArrayList;
import java.util.List;
import java.util.Objects;
import java.util.UUID;
```

Use the [S3 Transfer Manager](#) on top of the [AWS CRT-based S3 client](#) to transparently perform a multipart upload when the size of the content exceeds a threshold. The default threshold size is 8 MB.

```
public void multipartUploadWithTransferManager(String filePath) {
    S3TransferManager transferManager = S3TransferManager.create();
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
        .putObjectRequest(b -> b
            .bucket(bucketName)
            .key(key))
        .source(Paths.get(filePath))
        .build();
    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);
    fileUpload.completionFuture().join();
    transferManager.close();
}
```

Use the [S3Client API](#) or ([S3AsyncClient API](#)) to perform a multipart upload.

```
public void multipartUploadWithS3Client(String filePath) {

    // Initiate the multipart upload.
    CreateMultipartUploadResponse createMultipartUploadResponse =
s3Client.createMultipartUpload(b -> b
        .bucket(bucketName)
        .key(key));
    String uploadId = createMultipartUploadResponse.uploadId();

    // Upload the parts of the file.
    int partNumber = 1;
```

```
List<CompletedPart> completedParts = new ArrayList<>();
ByteBuffer bb = ByteBuffer.allocate(1024 * 1024 * 5); // 5 MB byte buffer

try (RandomAccessFile file = new RandomAccessFile(filePath, "r")) {
    long fileSize = file.length();
    int position = 0;
    while (position < fileSize) {
        file.seek(position);
        int read = file.getChannel().read(bb);

        bb.flip(); // Swap position and limit before reading from the
buffer.

        UploadPartRequest uploadPartRequest = UploadPartRequest.builder()
            .bucket(bucketName)
            .key(key)
            .uploadId(uploadId)
            .partNumber(partNumber)
            .build();

        UploadPartResponse partResponse = s3Client.uploadPart(
            uploadPartRequest,
            RequestBody.fromByteBuffer(bb));

        CompletedPart part = CompletedPart.builder()
            .partNumber(partNumber)
            .eTag(partResponse.eTag())
            .build();
        completedParts.add(part);

        bb.clear();
        position += read;
        partNumber++;
    }
} catch (IOException e) {
    logger.error(e.getMessage());
}

// Complete the multipart upload.
s3Client.completeMultipartUpload(b -> b
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)

    .multipartUpload(CompletedMultipartUpload.builder().parts(completedParts).build()));

```

```
}
```

Upload or download large files to and from Amazon S3 using an AWS SDK

The following code examples show how to upload or download large files to and from Amazon S3.

For more information, see [Uploading an object using multipart upload](#).

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Call functions that transfer files to and from an S3 bucket using the Amazon S3 TransferUtility.

```
global using System.Text;
global using Amazon.S3;
global using Amazon.S3.Model;
global using Amazon.S3.Transfer;
global using TransferUtilityBasics;
```

```
// This Amazon S3 client uses the default user credentials
// defined for this computer.
using Microsoft.Extensions.Configuration;

IAmazonS3 client = new AmazonS3Client();
var transferUtil = new TransferUtility(client);
IConfiguration _configuration;

_configuration = new ConfigurationBuilder()
    .SetBasePath(Directory.GetCurrentDirectory())
    .AddJsonFile("settings.json") // Load test settings from JSON file.
    .AddJsonFile("settings.local.json",
        true) // Optionally load local settings.
    .Build();

// Edit the values in settings.json to use an S3 bucket and files that
// exist on your AWS account and on the local computer where you
// run this scenario.
var bucketName = _configuration["BucketName"];
var localPath =
    $"{Environment.GetFolderPath(Environment.SpecialFolder.ApplicationData)}\\
TransferFolder";

DisplayInstructions();

PressEnter();

Console.WriteLine();

// Upload a single file to an S3 bucket.
DisplayTitle("Upload a single file");

var fileToUpload = _configuration["FileToUpload"];
Console.WriteLine($"Uploading {fileToUpload} to the S3 bucket, {bucketName}..");

var success = await TransferMethods.UploadSingleFileAsync(transferUtil,
    bucketName, fileToUpload, localPath);
if (success)
{
    Console.WriteLine($"Successfully uploaded the file, {fileToUpload} to
{bucketName}..");
}
```

```
PressEnter();

// Upload a local directory to an S3 bucket.
DisplayTitle("Upload all files from a local directory");

Upload a large object by using an upload manager to break the data into parts and upload them concurrently.

```
// BucketBasics encapsulates the Amazon Simple Storage Service (Amazon S3)
// actions
// used in the examples.
// It contains S3Client, an Amazon S3 service client that is used to perform
// bucket
// and object actions.
type BucketBasics struct {
    S3Client *s3.Client
}

// UploadLargeObject uses an upload manager to upload data to an object in a
// bucket.
// The upload manager breaks large data into parts and uploads the parts
// concurrently.
func (basics BucketBasics) UploadLargeObject(bucketName string, objectKey string,
    largeObject []byte) error {
    largeBuffer := bytes.NewReader(largeObject)
    var partMiBs int64 = 10
    uploader := manager.NewUploader(basics.S3Client, func(u *manager.Uploader) {
        u.PartSize = partMiBs * 1024 * 1024
    })
    _, err := uploader.Upload(context.TODO(), &s3.PutObjectInput{
        Bucket: aws.String(bucketName),
        Key:    aws.String(objectKey),
        Body:   largeBuffer,
    })
    if err != nil {
        log.Printf("Couldn't upload large object to %v:%v. Here's why: %v\n",
            bucketName, objectKey, err)
    }
    return err
}
```

Download a large object by using a download manager to get the data in parts and download them concurrently.

```
// DownloadLargeObject uses a download manager to download an object from a
// bucket.
// The download manager gets the data in parts and writes them to a buffer until
// all of
// the data has been downloaded.
func (basics BucketBasics) DownloadLargeObject(bucketName string, objectKey
string) ([]byte, error) {
    var partMiBs int64 = 10
    downloader := manager.NewDownloader(basics.S3Client, func(d *manager.Downloader)
{
    d.PartSize = partMiBs * 1024 * 1024
})
    buffer := manager.NewWriteAtBuffer([]byte{})
    _, err := downloader.Download(context.TODO(), buffer, &s3.GetObjectInput{
        Bucket: aws.String(bucketName),
        Key:    aws.String(objectKey),
    })
    if err != nil {
        log.Printf("Couldn't download large object from %v:%v. Here's why: %v\n",

Call functions that transfer files to and from an S3 bucket using the `S3TransferManager`.

```
public Integer downloadObjectsToDirectory(S3TransferManager transferManager,
    String destinationPath, String bucketName) {
    DirectoryDownload directoryDownload =
transferManager.downloadDirectory(DownloadDirectoryRequest.builder()
        .destination(Paths.get(destinationPath))
        .bucket(bucketName)
        .build());
    CompletedDirectoryDownload completedDirectoryDownload =
directoryDownload.completionFuture().join();

    completedDirectoryDownload.failedTransfers()
        .forEach(fail -> logger.warn("Object [{}] failed to transfer",
fail.toString()));
    return completedDirectoryDownload.failedTransfers().size();
}
```

Upload an entire local directory.

```
public Integer uploadDirectory(S3TransferManager transferManager,
    String sourceDirectory, String bucketName) {
    DirectoryUpload directoryUpload =
transferManager.uploadDirectory(UploadDirectoryRequest.builder()
        .source(Paths.get(sourceDirectory))
        .bucket(bucketName)
        .build());

    CompletedDirectoryUpload completedDirectoryUpload =
directoryUpload.completionFuture().join();
    completedDirectoryUpload.failedTransfers()
        .forEach(fail -> logger.warn("Object [{}] failed to transfer",
fail.toString()));
    return completedDirectoryUpload.failedTransfers().size();
}
```

Upload a single file.

```
public String uploadFile(S3TransferManager transferManager, String
bucketName,
    String key, String filePath) {
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
```

```
.putObjectRequest(b -> b.bucket(bucketName).key(key))
.addTransferListener(LoggingTransferListener.create())
.source(Paths.get(filePath))
.build();

FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);

CompletedFileUpload uploadResult = fileUpload.completionFuture().join();
return uploadResult.response().eTag();
}

Use checksums to work with an Amazon S3 object using an AWS SDK

The following code example shows how to use checksums to work with an Amazon S3 object.

Java

SDK for Java 2.x

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

The code examples use a subset of the following imports.

```
import org.slf4j.Logger;\nimport org.slf4j.LoggerFactory;\nimport software.amazon.awssdk.core.exception.SdkException;
```

```
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.ChecksumAlgorithm;
import software.amazon.awssdk.services.s3.model.ChecksumMode;
import software.amazon.awssdk.services.s3.model.CompletedMultipartUpload;
import software.amazon.awssdk.services.s3.model.CompletedPart;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadResponse;
import software.amazon.awssdk.services.s3.model.GetObjectResponse;
import software.amazon.awssdk.services.s3.model.UploadPartRequest;
import software.amazon.awssdk.services.s3.model.UploadPartResponse;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
import software.amazon.transfer.s3.S3TransferManager;
import software.amazon.transfer.s3.model.FileUpload;
import software.amazon.transfer.s3.model.UploadFileRequest;

import java.io.FileInputStream;
import java.io.IOException;
import java.io.RandomAccessFile;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.ByteBuffer;
import java.nio.file.Paths;
import java.security.DigestInputStream;
import java.security.MessageDigest;
import java.security.NoSuchAlgorithmException;
import java.util.ArrayList;
import java.util.Base64;
import java.util.List;
import java.util.Objects;
import java.util.UUID;
```

Specify a checksum algorithm for the `putObject` method when you [build the PutObjectRequest](#).

```
public void putObjectWithChecksum() {
    s3Client.putObject(b -> b
        .bucket(bucketName)
        .key(key)
        .checksumAlgorithm(ChecksumAlgorithm.CRC32),
        RequestBody.fromString("This is a test"));
}
```

Verify the checksum for the `getObject` method when you [build the `GetObjectRequest`](#).

```
public GetObjectResponse getObjectWithChecksum() {  
    return s3Client.getObject(b -> b  
        .bucket(bucketName)  
        .key(key)  
        .checksumMode(ChecksumMode.ENABLED))  
        .response();  
}
```

Pre-calculate a checksum for the `putObject` method when you [build the `PutObjectRequest`](#).

```
public void putObjectWithPrecalculatedChecksum(String filePath) {  
    String checksum = calculateChecksum(filePath, "SHA-256");  
  
    s3Client.putObject((b -> b  
        .bucket(bucketName)  
        .key(key)  
        .checksumSHA256(checksum)),  
        RequestBody.fromFile(Paths.get(filePath)));  
}
```

Use the [S3 Transfer Manager](#) on top of the [AWS CRT-based S3 client](#) to transparently perform a multipart upload when the size of the content exceeds a threshold. The default threshold size is 8 MB.

You can specify a checksum algorithm for the SDK to use. By default, the SDK uses the CRC32 algorithm.

```
public void multipartUploadWithChecksumTm(String filePath) {  
    S3TransferManager transferManager = S3TransferManager.create();  
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()  
        .putObjectRequest(b -> b  
            .bucket(bucketName)  
            .key(key)  
            .checksumAlgorithm(ChecksumAlgorithm.SHA1))  
        .source(Paths.get(filePath))  
        .build();
```

```
        FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);
        fileUpload.completionFuture().join();
        transferManager.close();
    }
```

Use the [S3Client API](#) or (S3AsyncClient API) to perform a multipart upload. If you specify an additional checksum, you must specify the algorithm to use on the initiation of the upload. You must also specify the algorithm for each part request and provide the checksum calculated for each part after it is uploaded.

```
public void multipartUploadWithChecksumS3Client(String filePath) {
    ChecksumAlgorithm algorithm = ChecksumAlgorithm.CRC32;

    // Initiate the multipart upload.
    CreateMultipartUploadResponse createMultipartUploadResponse =
s3Client.createMultipartUpload(b -> b
        .bucket(bucketName)
        .key(key)
        .checksumAlgorithm(algorithm)); // Checksum specified on
initiation.
    String uploadId = createMultipartUploadResponse.uploadId();

    // Upload the parts of the file.
    int partNumber = 1;
    List<CompletedPart> completedParts = new ArrayList<>();
    ByteBuffer bb = ByteBuffer.allocate(1024 * 1024 * 5); // 5 MB byte buffer

    try (RandomAccessFile file = new RandomAccessFile(filePath, "r")) {
        long fileSize = file.length();
        int position = 0;
        while (position < fileSize) {
            file.seek(position);
            int read = file.getChannel().read(bb);

            bb.flip(); // Swap position and limit before reading from the
buffer.
            UploadPartRequest uploadPartRequest = UploadPartRequest.builder()
                .bucket(bucketName)
                .key(key)
                .uploadId(uploadId)
                .checksumAlgorithm(algorithm) // Checksum specified on
each part.
```

```
        .partNumber(partNumber)
        .build();

        UploadPartResponse partResponse = s3Client.uploadPart(
            uploadPartRequest,
            RequestBody.fromByteBuffer(bb));

        CompletedPart part = CompletedPart.builder()
            .partNumber(partNumber)
            .checksumCRC32(partResponse.checksumCRC32()) // Provide
the calculated checksum.
            .eTag(partResponse.eTag())
            .build();
        completedParts.add(part);

        bb.clear();
        position += read;
        partNumber++;
    }
} catch (IOException e) {
    System.err.println(e.getMessage());
}

// Complete the multipart upload.
s3Client.completeMultipartUpload(b -> b
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)

    .multipartUpload(CompletedMultipartUpload.builder().parts(completedParts).build()));
}
```

Work with Amazon S3 versioned objects using an AWS SDK

The following code example shows how to:

- Create a versioned S3 bucket.
- Get all versions of an object.
- Roll an object back to a previous version.
- Delete and restore a versioned object.
- Permanently delete all versions of an object.

Python

SDK for Python (Boto3)

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create functions that wrap S3 actions.

```
def create_versioned_bucket(bucket_name, prefix):
    """
    Creates an Amazon S3 bucket, enables it for versioning, and configures a
    lifecycle
    that expires noncurrent object versions after 7 days.

    Adding a lifecycle configuration to a versioned bucket is a best practice.
    It helps prevent objects in the bucket from accumulating a large number of
    noncurrent versions, which can slow down request performance.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

    :param bucket_name: The name of the bucket to create.
    :param prefix: Identifies which objects are automatically expired under the
                   configured lifecycle rules.
    :return: The newly created bucket.
    """
```

```
try:  
    bucket = s3.create_bucket(  
        Bucket=bucket_name,  
        CreateBucketConfiguration={  
            "LocationConstraint": s3.meta.client.meta.region_name  
        },

Serverless examples for Amazon S3 using AWS SDKs

The following code examples show how to use Amazon S3 with AWS SDKs.

Examples

- [Invoke a Lambda function from an Amazon S3 trigger](#)

Invoke a Lambda function from an Amazon S3 trigger

The following code examples show how to implement a Lambda function that receives an event triggered by uploading an object to an S3 bucket. The function retrieves the S3 bucket name and object key from the event parameter and calls the Amazon S3 API to retrieve and log the content type of the object.

.NET

AWS SDK for .NET

Note

Cross-service examples for Amazon S3 using AWS SDKs

The following sample applications use AWS SDKs to combine Amazon S3 with other AWS services. Each example includes a link to GitHub, where you can find instructions on how to set up and run the application.

Examples

- [Build an Amazon Transcribe app](#)

- [Convert text to speech and back to text using an AWS SDK](#)
- [Create a photo asset management application that lets users manage photos using labels](#)
- [Create an Amazon Textract explorer application](#)
- [Detect PPE in images with Amazon Rekognition using an AWS SDK](#)
- [Detect entities in text extracted from an image using an AWS SDK](#)
- [Detect faces in an image using an AWS SDK](#)
- [Detect objects in images with Amazon Rekognition using an AWS SDK](#)
- [Detect people and objects in a video with Amazon Rekognition using an AWS SDK](#)
- [Save EXIF and other image information using an AWS SDK](#)

Build an Amazon Transcribe app

The following code example shows how to use Amazon Transcribe to transcribe and display voice recordings in the browser.

JavaScript

SDK for JavaScript (v3)

Create an app that uses Amazon Transcribe to transcribe and display voice recordings in the browser. The app uses two Amazon Simple Storage Service (Amazon S3) buckets, one to host the application code, and another to store transcriptions. The app uses an Amazon Cognito user pool to authenticate your users. Authenticated users have AWS Identity and Access Management (IAM) permissions to access the required AWS services.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

This example is also available in the [AWS SDK for JavaScript v3 developer guide](#).

Services used in this example

- Amazon Cognito Identity
- Amazon S3
- Amazon Transcribe

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Convert text to speech and back to text using an AWS SDK

The following code example shows how to:

- Use Amazon Polly to synthesize a plain text (UTF-8) input file to an audio file.
- Upload the audio file to an Amazon S3 bucket.
- Use Amazon Transcribe to convert the audio file to text.
- Display the text.

Rust

SDK for Rust

Use Amazon Polly to synthesize a plain text (UTF-8) input file to an audio file, upload the audio file to an Amazon S3 bucket, use Amazon Transcribe to convert that audio file to text, and display the text.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Polly
- Amazon S3
- Amazon Transcribe

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a photo asset management application that lets users manage photos using labels

The following code examples show how to create a serverless application that lets users manage photos using labels.

.NET

AWS SDK for .NET

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

C++

SDK for C++

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Java

SDK for Java 2.x

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Kotlin

SDK for Kotlin

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

PHP

SDK for PHP

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Rust

SDK for Rust

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create an Amazon Textract explorer application

The following code examples show how to explore Amazon Textract output through an interactive application.

JavaScript

SDK for JavaScript (v3)

Shows how to use the AWS SDK for JavaScript to build a React application that uses Amazon Textract to extract data from a document image and display it in an interactive web page. This example runs in a web browser and requires an authenticated Amazon Cognito identity for credentials. It uses Amazon Simple Storage Service (Amazon S3) for storage, and for notifications it polls an Amazon Simple Queue Service (Amazon SQS) queue that is subscribed to an Amazon Simple Notification Service (Amazon SNS) topic.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Cognito Identity
- Amazon S3
- Amazon SNS
- Amazon SQS
- Amazon Textract

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with Amazon Textract to detect text, form, and table elements in a document image. The input image and Amazon Textract output are shown in a Tkinter application that lets you explore the detected elements.

- Submit a document image to Amazon Textract and explore the output of detected elements.
- Submit images directly to Amazon Textract or through an Amazon Simple Storage Service (Amazon S3) bucket.

- Use asynchronous APIs to start a job that publishes a notification to an Amazon Simple Notification Service (Amazon SNS) topic when the job completes.
- Poll an Amazon Simple Queue Service (Amazon SQS) queue for a job completion message and display the results.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon S3
- Amazon SNS
- Amazon SQS
- Amazon Textract

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Detect PPE in images with Amazon Rekognition using an AWS SDK

The following code examples show how to build an app that uses Amazon Rekognition to detect Personal Protective Equipment (PPE) in images.

Java

SDK for Java 2.x

Shows how to create an AWS Lambda function that detects images with Personal Protective Equipment.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3

- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use Amazon Rekognition with the AWS SDK for JavaScript to create an application to detect personal protective equipment (PPE) in images located in an Amazon Simple Storage Service (Amazon S3) bucket. The app saves the results to an Amazon DynamoDB table, and sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

Learn how to:

- Create an unauthenticated user using Amazon Cognito.
- Analyze images for PPE using Amazon Rekognition.
- Verify an email address for Amazon SES.
- Update a DynamoDB table with results.
- Send an email notification using Amazon SES.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Detect entities in text extracted from an image using an AWS SDK

The following code example shows how to use Amazon Comprehend to detect entities in text extracted by Amazon Textract from an image that is stored in Amazon S3.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) in a Jupyter notebook to detect entities in text that is extracted from an image. This example uses Amazon Textract to extract text from an image stored in Amazon Simple Storage Service (Amazon S3) and Amazon Comprehend to detect entities in the extracted text.

This example is a Jupyter notebook and must be run in an environment that can host notebooks. For instructions on how to run the example using Amazon SageMaker, see the directions in [TextractAndComprehendNotebook.ipynb](#).

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Comprehend
- Amazon S3
- Amazon Textract

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Detect faces in an image using an AWS SDK

The following code example shows how to:

- Save an image in an Amazon S3 bucket.
- Use Amazon Rekognition to detect facial details, such as age range, gender, and emotion (such as smiling).
- Display those details.

Rust

SDK for Rust

Save the image in an Amazon S3 bucket with an **uploads** prefix, use Amazon Rekognition to detect facial details, such as age range, gender, and emotion (smiling, etc.), and display those details.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Rekognition
- Amazon S3

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Detect objects in images with Amazon Rekognition using an AWS SDK

The following code examples show how to build an app that uses Amazon Rekognition to detect objects by category in images.

.NET

AWS SDK for .NET

Shows how to use Amazon Rekognition .NET API to create an app that uses Amazon Rekognition to identify objects by category in images located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Rekognition

- Amazon S3
- Amazon SES

Java

SDK for Java 2.x

Shows how to use Amazon Rekognition Java API to create an app that uses Amazon Rekognition to identify objects by category in images located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use Amazon Rekognition with the AWS SDK for JavaScript to create an app that uses Amazon Rekognition to identify objects by category in images located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

Learn how to:

- Create an unauthenticated user using Amazon Cognito.
- Analyze images for objects using Amazon Rekognition.
- Verify an email address for Amazon SES.
- Send an email notification using Amazon SES.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES

Kotlin

SDK for Kotlin

Shows how to use Amazon Rekognition Kotlin API to create an app that uses Amazon Rekognition to identify objects by category in images located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES

Python

SDK for Python (Boto3)

Shows you how to use the AWS SDK for Python (Boto3) to create a web application that lets you do the following:

- Upload photos to an Amazon Simple Storage Service (Amazon S3) bucket.
- Use Amazon Rekognition to analyze and label the photos.
- Use Amazon Simple Email Service (Amazon SES) to send email reports of image analysis.

This example contains two main components: a webpage written in JavaScript that is built with React, and a REST service written in Python that is built with Flask-RESTful.

You can use the React webpage to:

- Display a list of images that are stored in your S3 bucket.

- Upload images from your computer to your S3 bucket.
- Display images and labels that identify items that are detected in the image.
- Get a report of all images in your S3 bucket and send an email of the report.

The webpage calls the REST service. The service sends requests to AWS to perform the following actions:

- Get and filter the list of images in your S3 bucket.
- Upload photos to your S3 bucket.
- Use Amazon Rekognition to analyze individual photos and get a list of labels that identify items that are detected in the photo.
- Analyze all photos in your S3 bucket and use Amazon SES to email a report.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Detect people and objects in a video with Amazon Rekognition using an AWS SDK

The following code examples show how to detect people and objects in a video with Amazon Rekognition.

Java

SDK for Java 2.x

Shows how to use Amazon Rekognition Java API to create an app to detect faces and objects in videos located in an Amazon Simple Storage Service (Amazon S3) bucket. The app

sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use Amazon Rekognition with the AWS SDK for JavaScript to create an app to detect faces and objects in videos located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

Learn how to:

- Create an unauthenticated user using Amazon Cognito.
- Analyze images for PPE using Amazon Rekognition.
- Verify an email address for Amazon SES.
- Send an email notification using Amazon SES.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Save EXIF and other image information using an AWS SDK

The following code example shows how to:

- Get EXIF information from a a JPG, JPEG, or PNG file.
- Upload the image file to an Amazon S3 bucket.
- Use Amazon Rekognition to identify the three top attributes (*labels*) in the file.
- Add the EXIF and label information to an Amazon DynamoDB table in the Region.

Rust

SDK for Rust

Get EXIF information from a JPG, JPEG, or PNG file, upload the image file to an Amazon S3 bucket, use Amazon Rekognition to identify the three top attributes (*labels* in Amazon Rekognition) in the file, and add the EXIF and label information to a Amazon DynamoDB table in the Region.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Troubleshooting

This section describes how to troubleshoot Amazon S3 features and explains how to get request IDs that you'll need when you contact AWS Support.

Topics

- [Troubleshoot Access Denied \(403 Forbidden\) errors in Amazon S3](#)
- [Troubleshoot Batch Operations](#)
- [Troubleshoot CORS](#)
- [Troubleshoot Amazon S3 Lifecycle issues](#)
- [Troubleshooting replication](#)
- [Troubleshoot server access logging](#)
- [Troubleshoot versioning](#)
- [Getting Amazon S3 request IDs for AWS Support](#)

Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3

The following topics cover the most common causes of Access Denied (403 Forbidden) errors in Amazon S3.

Topics

- [Bucket policies and IAM policies](#)
- [Amazon S3 ACL settings](#)
- [S3 Block Public Access settings](#)
- [Amazon S3 encryption settings](#)
- [S3 Object Lock settings](#)
- [VPC endpoint policy](#)
- [AWS Organizations policies](#)
- [Access point settings](#)

Note

If you're trying to troubleshoot a permissions issue, start with the [Bucket policies and IAM policies](#) section, and be sure to follow the guidance in [Tips for checking permissions](#).

Bucket policies and IAM policies

Bucket-level operations

If there is no bucket policy in place, then the bucket implicitly allows requests from any AWS Identity and Access Management (IAM) identity in the bucket-owning account. The bucket also implicitly denies requests from any other IAM identities from any other accounts, and anonymous (unsigned) requests. However, if there is no IAM user policy in place, the requester (unless they are the root user) is implicitly denied from making any requests. For more information about this evaluation logic, see [Determining whether a request is denied or allowed within an account](#) in the *IAM User Guide*.

Object-level operations

If the object is owned by the bucket-owning account, the bucket policy and IAM user policy will function in the same way for object-level operations as they do for bucket-level operations. For example, if there is no bucket policy in place, then the bucket implicitly allows object requests from any IAM identity in the bucket-owning account. The bucket also implicitly denies object requests from any other IAM identities from any other accounts, and anonymous (unsigned) requests. However, if there is no IAM user policy in place, the requester (unless they are the root user) is implicitly denied from making any object requests.

If the object is owned by an external account, then access to the object can be granted only through object access control lists (ACLs). The bucket policy and IAM user policy can still be used to deny object requests.

Therefore, to ensure that your bucket policy or IAM user policy is not causing an Access Denied (403 Forbidden) error, make sure that the following requirements are met:

- For same-account access, there must not be an explicit Deny statement against the requester you are trying to grant permissions to, in either the bucket policy or the IAM user policy. If you want to grant permissions by using only the bucket policy and the IAM user policy, there must be at least one explicit Allow statement in one of these policies.

- For cross-account access, there must not be an explicit Deny statement against the requester you are trying to grant permissions to, in either the bucket policy or the IAM user policy. If you want to grant cross-account permissions by using only the bucket policy and IAM user policy, then both the bucket policy and the IAM user policy of the requester must include an explicit Allow statement.

 **Note**

Allow statements in a bucket policy apply only to objects that are [owned by the same bucket-owning account](#). However, Deny statements in a bucket policy apply to all objects regardless of object ownership.

To review or edit your bucket policy

 **Note**

To view or edit a bucket policy, you must have the `s3:GetBucketPolicy` permission.

- Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
- In the left navigation pane, choose **Buckets**.
- From the **Buckets** list, choose the name of the bucket that you want to view or edit a bucket policy for.
- Choose the **Permissions** tab.
- Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.

To review or edit your bucket policy by using the AWS Command Line Interface (AWS CLI), use the [get-bucket-policy](#) command.

Note

If you get locked out of a bucket because of an incorrect bucket policy, [sign in to the AWS Management Console by using your root user credentials](#). To regain access to your bucket, make sure to delete the bucket policy by using your root user credentials.

Tips for checking permissions

To check whether the requester has proper permissions to perform an Amazon S3 operation, try the following:

- Identify the requester. If it's an unsigned request, then it's an anonymous request without an IAM user policy. If it's a request using a presigned URL, then the user policy will be the same as the one for the IAM user or role that signed the request.
- Verify that you're using the correct IAM user or role. You can verify your IAM user or role by checking the upper-right corner of the AWS Management Console or by using the [aws sts get-caller-identity](#) command.
- Check the IAM policies that are related to the IAM user or role. You can use one of the following methods:
 - [Test IAM policies with the IAM policy simulator](#).
 - Review the different [IAM policy types](#).
- If needed, [edit your IAM user policy](#).
- Review the following examples of policies that explicitly deny or allow access:
 - Explicit allow IAM user policy: [IAM: Allows and denies access to multiple services programmatically and in the console](#)
 - Explicit allow bucket policy: [Granting permissions to multiple accounts to upload objects or set object ACLs for public access](#)
 - Explicit deny IAM user policy: [AWS: Denies access to AWS based on the requested AWS Region](#)
 - Explicit deny bucket policy: [Require SSE-KMS for all objects written to a bucket](#)

Amazon S3 ACL settings

When checking your ACL settings, first [review your Object Ownership setting](#) to check whether ACLs are enabled on the bucket. Be aware that ACL permissions can be used only to grant

permissions and cannot be used to reject requests. ACLs also cannot be used to grant access to requesters that are rejected by explicit denials in bucket policies or IAM user policies.

The Object Ownership setting is set to bucket owner enforced

If the bucket owner enforced setting is enabled, then ACL settings are unlikely to cause an Access Denied (403 Forbidden) error because this setting disables all ACLs that apply to bucket and objects. Bucket owner enforced is the default (and recommended) setting for Amazon S3 buckets.

The Object Ownership setting is set to bucket owner preferred or object writer

ACL permissions are still valid with the bucket owner preferred setting or the object writer setting. There are two kinds of ACLs: bucket ACLs and object ACLs. For the differences between these two types of ACLs, see [Mapping of ACL permissions and access policy permissions](#).

Depending on the action of the rejected request, [check the ACL permissions for your bucket or the object](#):

- If Amazon S3 rejected a LIST, PUT object, GetBucketAcl, or PutBucketAcl request, then [review the ACL permissions for your bucket](#).

 **Note**

You cannot grant GET object permissions with bucket ACL settings.

- If Amazon S3 rejected a GET request on an S3 object, or a [PutObjectAcl](#) request, then [review the ACL permissions for the object](#).

 **Important**

If the account that owns the object is different from the account that owns the bucket, then access to the object isn't controlled by the bucket policy.

Troubleshooting an Access Denied (403 Forbidden) error from a GET object request during cross-account object ownership

Review the bucket's [Object Ownership settings](#) to determine the object owner. If you have access to the [object ACLs](#), then you can also check the object owner's account. (To view the object owner's

account, review the object ACL setting in the Amazon S3 console.) Alternatively, you can also make a `GetObjectAcl` request to find the object owner's [canonical ID](#) to verify the object owner account. By default, ACLs grant explicit allow permissions for GET requests to the object owner's account.

After you've confirmed that the object owner is different from the bucket owner, then depending on your use case and access level, choose one of the following methods to help address the Access Denied (403 Forbidden) error:

- **Disable ACLs (recommended)** – This method will apply to all objects and can be performed by the bucket owner. This method automatically gives the bucket owner ownership and full control over every object in the bucket. Before you implement this method, check the [prerequisites for disabling ACLs](#). For information about how to set your bucket to bucket owner enforced (recommended) mode, see [Setting Object Ownership on an existing bucket](#).

 **Important**

To prevent an Access Denied (403 Forbidden) error, be sure to migrate the ACL permissions to a bucket policy before you disable ACLs. For more information, see [Bucket policy examples for migrating from ACL permissions](#).

- **Change the object owner to the bucket owner** – This method can be applied to individual objects, but only the object owner (or a user with the appropriate permissions) can change an object's ownership. Additional PUT costs might apply. (For more information, see [Amazon S3 pricing](#).) This method grants the bucket owner full ownership of the object, allowing the bucket owner to control access to the object through a bucket policy.

To change the object's ownership, do one of the following:

- You (the bucket owner) can [copy the object](#) back to the bucket.
- You can change the Object Ownership setting of the bucket to bucket owner preferred. If versioning is disabled, the objects in the bucket are overwritten. If versioning is enabled, duplicate versions of the same object will appear in the bucket, which the bucket owner can [set a lifecycle rule to expire](#). For instructions on how to change your Object Ownership setting, see [Setting Object Ownership on an existing bucket](#).

Note

When you update your Object Ownership setting to bucket owner preferred, the setting is only applied to new objects that are uploaded to the bucket.

- You can have the object owner upload the object again with the `bucket-owner-full-control` canned object ACL.

Note

For cross-account uploads, you can also require the `bucket-owner-full-control` canned object ACL in your bucket policy. For an example bucket policy, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control](#).

- **Keep the object writer as the object owner** – This method doesn't change the object owner, but it does allow you to grant access to objects individually. To grant access to an object, you must have the `PutObjectAcl` permission for the object. Then, to fix the Access Denied (403 Forbidden) error, add the requester as a [grantee](#) to access the object in the object's ACLs. For more information, see [Configuring ACLs](#).

S3 Block Public Access settings

If the failed request involves public access or public policies, then check the S3 Block Public Access settings on your account, bucket, or S3 access point. Starting in April 2023, all Block Public Access settings are enabled by default for new buckets. For more information about how Amazon S3 defines "public," see [The meaning of "public"](#).

When set to TRUE, Block Public Access settings act as explicit deny policies that override permissions allowed by ACLs, bucket policies, and IAM user policies. To determine whether your Block Public Access settings are rejecting your request, review the following scenarios:

- If the specified access control list (ACL) is public, then the `BlockPublicAcls` setting rejects your `PutBucketAcl` and `PutObjectAcl` calls.
- If the request includes a public ACL, then the `BlockPublicAcls` setting rejects your `PutObject` calls.

- If the `BlockPublicAcls` setting is applied to an account and the request includes a public ACL, then any `CreateBucket` calls that include public ACLs will fail.
- If your request's permission is granted only by a public ACL, then the `IgnorePublicAcls` setting rejects the request.
- If the specified bucket policy allows public access, then the `BlockPublicPolicy` setting rejects your `PutBucketPolicy` calls.
- If the `BlockPublicPolicy` setting is applied to an access point, then all `PutAccessPointPolicy` and `PutBucketPolicy` calls that specify a public policy and are made through the access point will fail.
- If the access point or bucket has a public policy, then the `RestrictPublicBuckets` setting rejects all cross-account calls except for AWS service principals. This setting also rejects all anonymous (or unsigned) calls.

To review and update your Block Public Access setting configurations, see [Configuring block public access settings for your S3 buckets](#).

Amazon S3 encryption settings

Amazon S3 supports server-side encryption on your bucket. Server-side encryption is the encryption of data at its destination by the application or service that receives it. Amazon S3 encrypts your data at the object level as it writes it to disks in AWS data centers and decrypts it for you when you access it.

By default, Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Amazon S3 also allows you to specify the server-side encryption method when uploading objects.

To review your bucket's server-side encryption status and encryption settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the bucket that you want to check the encryption settings for.
4. Choose the **Properties** tab.
5. Scroll down to the **Default encryption** section and view the **Encryption type** settings.

To check your encryption settings by using the AWS CLI, use the [get-bucket-encryption](#) command.

To check the encryption status of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Buckets**.

3. From the **Buckets** list, choose the name of the bucket that contains the object.

4. From the **Objects** list, choose the name of the object that you want to add or change encryption for.

The object's details page appears.

5. Scroll down to the **Server-side encryption settings** section to view the object's server-side encryption settings.

To check your object encryption status by using the AWS CLI, use the [head-object](#) command.

Encryption and permissions requirements

Amazon S3 supports three types of server-side encryption:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

Based on your encryption settings, make sure that the following permissions requirements are met:

- **SSE-S3** – No extra permissions are required.
- **SSE-KMS (with a customer managed key)** – To upload objects, the `kms:GenerateDataKey` permission on the AWS KMS key is required. To download objects and perform multipart uploads of objects, the `kms:Decrypt` permission on the KMS key is required.
- **SSE-KMS (with an AWS managed key)** – The requester must be from the same account that owns the `aws/s3` KMS key. The requester must also have the correct Amazon S3 permissions to access the object.

- **SSE-C (with a customer provided key)** – No additional permissions are required. You can configure the bucket policy to [require and restrict server-side encryption with customer-provided encryption keys](#) for objects in your bucket.

If the object is encrypted with a customer managed key, make sure that the KMS key policy allows you to perform the kms:GenerateDataKey or kms:Decrypt actions. For instructions on checking your KMS key policy, see [Viewing a key policy](#) in the *AWS Key Management Service Developer Guide*.

S3 Object Lock settings

If your bucket has [S3 Object Lock](#) enabled and the object is protected by a [retention period](#) or [legal hold](#), Amazon S3 returns an Access Denied (403 Forbidden) error when you try to delete the object.

To check whether the bucket has Object Lock enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that you want to review.
4. Choose the **Properties** tab.
5. Scroll down to the **Object Lock** section. Verify whether the **Object Lock** setting is **Enabled** or **Disabled**.

To determine whether the object is protected by a retention period or legal hold, [view the lock information](#) for your object.

If the object is protected by a retention period or legal hold, check the following:

- If the object version is protected by the compliance retention mode, there is no way to permanently delete it. A permanent DELETE request from any requester, including the root user, will result in an Access Denied (403 Forbidden) error. Also, be aware that when you submit a DELETE request for an object that's protected by the compliance retention mode, Amazon S3 creates a [delete marker](#) for the object.
- If the object version is protected with governance retention mode and you have the s3:BypassGovernanceRetention permission, you can bypass the protection and permanently delete the version. For more information, see [Bypassing governance mode](#).

- If the object version is protected by a legal hold, then a permanent DELETE request can result in an Access Denied (403 Forbidden) error. To permanently delete the object version, you must remove the legal hold on the object version. To remove a legal hold, you must have the s3:PutObjectLegalHold permission. For more information about removing a legal hold, see [Configuring S3 Object Lock](#).

VPC endpoint policy

If you're accessing Amazon S3 by using a virtual private cloud (VPC) endpoint, make sure that the VPC endpoint policy is not blocking you from accessing your Amazon S3 resources. By default, the VPC endpoint policy allows all requests to Amazon S3. You can also configure the VPC endpoint policy to restrict certain requests. For information about how to check your VPC endpoint policy, see [Control access to VPC endpoints by using endpoint policies](#) in the *AWS PrivateLink Guide*.

AWS Organizations policies

If your AWS account belongs to an organization, AWS Organizations policies can block you from accessing Amazon S3 resources. By default, AWS Organizations policies do not block any requests to Amazon S3. However, make sure that your AWS Organizations policies haven't been configured to block access to S3 buckets. For instructions on how to check your AWS Organizations policies, see [Listing all policies](#) in the *AWS Organizations User Guide*.

Access point settings

If you receive an Access Denied (403 Forbidden) error while making requests through Amazon S3 access points, you might need to check the following:

- The configurations for your access points
- The IAM user policy that's used for your access points
- The bucket policy that's used to manage or configure your cross-account access points

Access point configurations and policies

- When you create an access point, you can choose to designate **Internet** or **VPC** as the network origin. If the network origin is set to VPC only, Amazon S3 will reject any requests made to the access point that don't originate from the specified VPC. To check the network origin of your access point, see [Creating access points restricted to a virtual private cloud](#).

- With access points, you can also configure custom Block Public Access settings, which work similarly to the Block Public Access settings at the bucket or account level. To check your custom Block Public Access settings, see [Managing public access to access points](#).
- To make successful requests to Amazon S3 by using access points, make sure that the requester has the necessary IAM permissions. For more information, see [Configuring IAM policies for using access points](#).
- If the request involves cross-account access points, make sure that the bucket owner has updated the bucket policy to authorize requests from the access point. For more information, see [Granting permissions for cross-account access points](#).

If the Access Denied (403 Forbidden) error still persists after checking all the items in this topic, [retrieve your Amazon S3 request ID](#) and contact AWS Support for additional guidance.

Troubleshoot Batch Operations

The following topics list common errors to help you troubleshoot issues that you might encounter during Batch Operations.

Common Errors

- [Job report isn't delivered when there is a permissions issue or an S3 Object Lock retention mode is enabled](#)
- [S3 Batch Replication failure with error: Manifest generation found no keys matching the filter criteria](#)
- [Batch Operations failures occur after adding a new replication rule to an existing replication configuration](#)
- [Batch Operations failing objects with the error 400 InvalidRequest: Task failed due to missing VersionId](#)
- [Create job failure with job tag option enabled](#)
- [Access Denied to read the manifest](#)

Job report isn't delivered when there is a permissions issue or an S3 Object Lock retention mode is enabled

The following error occurs if required permissions are missing or Object Lock retention mode (either governance mode or compliance mode) is enabled on the destination bucket.

Error: Reasons for failure. The job report could not be written to your report bucket. Please check your permissions.

The IAM role and trust policy must be configured to allow S3 Batch Operations access to PUT objects in the bucket where the report will be delivered. If these required permissions are missing a job report delivery failure occurs.

When a retention mode is enabled, the bucket is write-once-read-many (WORM) protected. Object Lock with retention mode enabled on the destination bucket is not supported so job completion report delivery attempts fail. To fix this problem, choose a destination bucket for your job completion reports that doesn't have an Object Lock retention mode enabled.

S3 Batch Replication failure with error: Manifest generation found no keys matching the filter criteria

The following error occurs when objects in the source bucket are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.

Error: Manifest generation found no keys matching the filter criteria.

Note

If the provided filter criteria doesn't match any valid objects in the source bucket, this error may be expected behavior. Verify the filter criteria and the target object storage class.

To use Batch Replication on these objects, first restore them to the S3 Standard storage class by using an S3 Initiate Restore Object operation in a Batch Operations job. For more information, see [Restoring an archived object](#) and [Restore objects \(Batch Operations\)](#). After you've restored the objects, you can replicate them by using a Batch Replication job.

Batch Operations failures occur after adding a new replication rule to an existing replication configuration

Batch Operations attempts to perform existing object replication for every rule in the source bucket's replication configuration. If there are problems with any of the existing replication rules, failures might occur.

The Batch Operations job's completion report explains the job failure reasons. For a list of common errors, see [Amazon S3 replication failure reasons](#).

Batch Operations failing objects with the error 400 InvalidRequest: Task failed due to missing VersionId

The following example error occurs if a Batch Operations job is performing actions on objects in a versioned bucket and encounters an object in the manifest with an empty version ID field.

Error: *BUCKET_NAME, prefix/file_name*,failed,400,InvalidRequest,Task failed due to missing VersionId

This error occurs because the version ID field in the manifest is an empty string, instead of the literal null string.

Batch Operations will fail for that particular object or objects, but not the entire job. This problem occurs if the manifest format is configured to use version IDs during the operation. Non-versioned jobs don't encounter this issue because they operate only on the most recent version of each object and ignore the version IDs in the manifest.

To fix this problem, convert the empty version IDs to null strings. For more information, see [the section called "Converting empty version ID strings to null strings"](#).

Create job failure with job tag option enabled

Without the `s3:PutJobTagging` permission, creating Batch Operations jobs with the job tag option enabled causes `403 access denied` errors.

To create Batch Operations jobs with the job tag option enabled, the AWS Identity and Access Management (IAM) user that's creating the Batch Operations job must have the `s3:PutJobTagging` permission in addition to the `s3:CreateJob` permission.

For more information about the permissions required for Batch Operations, see [the section called "Granting permissions"](#).

Access Denied to read the manifest

If Batch Operations can't read the manifest file when you attempt to create a Batch Operations job, the following errors can occur.

AWS CLI

Reason for failure Reading the manifest is forbidden: AccessDenied

Amazon S3 console

Warning: Unable to get the manifest object's ETag. Specify a different object to continue.

To solve this problem, do the following:

- Verify that the IAM role for the AWS account that you used to create the Batch Operations job has `s3:GetObject` permissions. The account's IAM role must have `s3:GetObject` permissions to allow Batch Operations to read the manifest file.

For more information about the permissions required for Batch Operations, see [the section called "Granting permissions"](#).

- Check the manifest objects' metadata for any access mismatches with S3 Object Ownership. For more information about S3 Object Ownership, see [the section called "Controlling object ownership"](#).
- Check whether AWS Key Management Service (AWS KMS) keys are used to encrypt the manifest file.

Batch Operations support *CSV inventory reports* that are AWS KMS-encrypted. However, Batch Operations don't support *CSV manifest files* that are AWS KMS-encrypted. For more information, see [Configuring Amazon S3 Inventory](#) and [Specifying a manifest](#).

Troubleshoot CORS

If you encounter unexpected behavior while accessing buckets set with the CORS configuration, try the following steps to troubleshoot:

1. Verify that the CORS configuration is set on the bucket.

If the CORS configuration is set, the console displays an **Edit CORS Configuration** link in the **Permissions** section of the **Properties** bucket.

2. Capture the complete request and response using a tool of your choice. For each request Amazon S3 receives, there must be a CORS rule that matches the data in your request, as follows:

- a. Verify that the request has the Origin header.

If the header is missing, Amazon S3 doesn't treat the request as a cross-origin request, and doesn't send CORS response headers in the response.

- b. Verify that the Origin header in your request matches at least one of the AllowedOrigin elements in the specified CORSRule.

The scheme, the host, and the port values in the Origin request header must match the AllowedOrigin elements in the CORSRule. For example, if you set the CORSRule to allow the origin `http://www.example.com`, then both `https://www.example.com` and `http://www.example.com:80` origins in your request don't match the allowed origin in your configuration.

- c. Verify that the method in your request (or in a preflight request, the method specified in the Access-Control-Request-Method) is one of the AllowedMethod elements in the same CORSRule.
- d. For a preflight request, if the request includes an Access-Control-Request-Headers header, verify that the CORSRule includes the AllowedHeader entries for each value in the Access-Control-Request-Headers header.

Troubleshoot Amazon S3 Lifecycle issues

The following information can help you troubleshoot common issues with Amazon S3 Lifecycle rules.

Topics

- [I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.](#)
- [How do I monitor the progress of my lifecycle rule to verify that it's active?](#)
- [My S3 object count still increases, even after setting up lifecycle rules on a version-enabled bucket.](#)
- [How do I empty my S3 bucket by using lifecycle rules?](#)
- [My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.](#)
- [I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.](#)
- [Can I recover S3 objects that are expired by S3 Lifecycle rules?](#)

I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.

S3 Lifecycle [object transitions](#) and [object expirations](#) are asynchronous operations. Therefore, there might be a delay between the time that the objects are eligible for expiration or transition and the time that they are actually transitioned or expired. Changes in billing are applied as soon as the lifecycle rule is satisfied, even if the action isn't complete. The exception to this behavior is if you have a lifecycle rule set to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes don't occur until the object has transitioned to S3 Intelligent-Tiering. For more information about changes in billing, see [Setting lifecycle configuration on a bucket](#).

Note

Amazon S3 doesn't transition objects that are smaller than 128 KB from the S3 Standard or S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage class.

How do I monitor the progress of my lifecycle rule to verify that it's active?

To view the progress of (or to monitor changes made by) any active lifecycle rules, [use the Storage Lens dashboard](#). With the dashboard, you can view the following metrics, which monitor the object count or size.

- **Current version bytes**
- **Current version object count**
- **Noncurrent version bytes**
- **Noncurrent version object count**
- **Delete marker object count**
- **Delete marker storage bytes**
- **Incomplete multipart upload bytes**
- **Incomplete multipart upload object count**

You can also use the following features to monitor your lifecycle rules:

- [Amazon S3 Inventory](#) – You can use S3 Inventory to generate the list of prefixes or objects for the Amazon S3 bucket (in CSV), Apache optimized row columnar (ORC), or Apache Parquet format for auditing purposes. Depending on your use case, you can also query S3 Inventory in standard SQL with Amazon Athena.
- [S3 Event Notifications](#) – You can set up event notifications so that you're notified of any lifecycle expiration or transition events.
- S3 server access logs – You can enable server access logs for the S3 bucket to capture lifecycle-related actions, such as object transitions to another storage class and object expirations. For more information, see [Lifecycle and logging](#).

My S3 object count still increases, even after setting up lifecycle rules on a version-enabled bucket.

When an object is set to be expired in a [versioning-enabled bucket](#), the object isn't completely deleted from the bucket. Instead, a [delete marker](#) is created as the newest version of the object. Delete markers are still counted as objects. Therefore, if a lifecycle rule is created to expire only the current versions, then the object count in the S3 bucket actually increases instead of going down.

For example, let's say an S3 bucket is versioning-enabled with 100 objects, and a lifecycle rule is set to expire current versions of the object after 7 days. After the seventh day, the object count increases to 200 because 100 delete markers are created in addition to the 100 original objects, which are now the noncurrent versions. For more information about S3 Lifecycle configuration rule actions for versioning-enabled buckets, see [Setting lifecycle configuration on a bucket](#).

To permanently remove objects, add an additional lifecycle configuration to delete the previous versions of the objects, expired delete markers, and incomplete multipart uploads. For instructions on how to create new lifecycle rules, see [Setting lifecycle configuration on a bucket](#).

Note

- Amazon S3 rounds the transition or expiration date of an object to midnight UTC the next day. For more information, see [Lifecycle rules: Based on an object's age](#).
- For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

How do I empty my S3 bucket by using lifecycle rules?

S3 Lifecycle rules are an effective tool to [empty an S3 bucket](#) with millions of objects. To delete a large number of objects from your S3 bucket, make sure to use these four pairs of lifecycle rules:

- **Expire current versions of objects** and **Permanently delete previous versions of objects**
- **Delete expired delete markers** and **Delete incomplete multipart uploads**

For steps on how to create a lifecycle configuration rule, see [Setting lifecycle configuration on a bucket](#).

 **Note**

For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.

There are several reasons that your bill might increase after transitioning objects to a lower-cost storage class:

- S3 Glacier overhead charges for small objects

For each object that is transitioned to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, a total overhead of 40 KB is associated with this storage update. As part of the 40 KB overhead, 8 KB is used to store metadata and the name of the object. This 8 KB is charged according to S3 Standard rates. The remaining 32 KB is used for indexing and related metadata. This 32 KB is charged according to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive pricing.

Therefore, if you're storing many smaller sized objects, we don't recommend using lifecycle transitions. Instead, to reduce any overhead charges, consider aggregating many smaller objects into a smaller number of large objects before storing them in Amazon S3. For more information about cost considerations, see [Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes \(object archival\)](#).

- Minimum storage charges

Some S3 storage classes have minimum storage-duration requirements. Objects that are deleted, overwritten, or transitioned from those classes before the minimum duration is satisfied are charged a prorated early transition or deletion fee. These minimum storage-duration requirements are as follows:

- S3 Standard-IA and S3 One Zone-IA – 30 days
- S3 Glacier Flexible Retrieval and S3 Glacier Instant Retrieval – 90 days
- S3 Glacier Deep Archive – 180 days

For more information about these requirements, see the *Constraints* section of [Transitioning objects using S3 Lifecycle](#). For general S3 pricing information, see [Amazon S3 pricing](#) and the [AWS Pricing Calculator](#).

- Lifecycle transition costs

Each time an object is transitioned to a different storage class by a lifecycle rule, Amazon S3 counts that transition as one transition request. The costs for these transition requests are in addition to the costs of these storage classes. If you plan to transition a large number of objects, consider the request costs when transitioning to a lower tier. For more information, see [Amazon S3 pricing](#).

I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.

Deny statements in a bucket policy don't prevent the expiration of the objects defined in a lifecycle rule. Lifecycle actions (such as transitions or expirations) don't use the S3 DeleteObject operation. Instead, S3 Lifecycle actions are performed by using internal S3 endpoints. (For more information, see [Lifecycle and logging](#).)

To prevent your lifecycle rule from taking any action, you must edit, delete, or [disable the rule](#).

Can I recover S3 objects that are expired by S3 Lifecycle rules?

The only way to recover objects that are expired by S3 Lifecycle is through versioning, which must be in place before the objects become eligible for expiration. You cannot undo the expiration operations that are performed by lifecycle rules. If objects are permanently deleted by the S3 Lifecycle rules that are in place, you cannot recover these objects. To enable versioning on a bucket, see [the section called "Using S3 Versioning"](#).

If you have applied versioning to the bucket and the noncurrent versions of the objects are still intact, you can [restore previous versions of the expired objects](#). For more information about the behavior of S3 Lifecycle rule actions and versioning states, see the *Lifecycle actions and bucket versioning state* table in [Elements to describe lifecycle actions](#).

 **Note**

If the S3 bucket is protected by [AWS Backup](#) or [S3 Replication](#), you might also be able to use these features to recover your expired objects.

Troubleshooting replication

This section lists troubleshooting tips for Amazon S3 Replication and information about S3 Batch Replication errors.

Topics

- [Troubleshooting tips for S3 Replication](#)
- [Batch Replication errors](#)

Troubleshooting tips for S3 Replication

If object replicas don't appear in the destination bucket after you configure replication, use these troubleshooting tips to identify and fix issues.

- The majority of objects replicate within 15 minutes. The time that it takes Amazon S3 to replicate an object depends on several factors, including the source and destination Region pair, and the size of the object. For large objects, replication can take up to several hours. For visibility into replication times, you can [use S3 Replication Time Control \(S3 RTC\)](#).

If the object that is being replicated is large, wait a while before checking to see whether it appears in the destination. You can also check the replication status of the source object. If the object replication status is PENDING, Amazon S3 has not completed the replication. If the object replication status is FAILED, check the replication configuration that's set on the source bucket. Additionally, to receive information about failures during replication, you can set up Amazon S3 Event Notifications replication to receive failure events. For more information, see [Receiving replication failure events with Amazon S3 Event Notifications](#).

- You can call the HeadObject API operation to check the replication status of an object. The HeadObject API operation returns the PENDING,COMPLETED, or FAILED replication status of an object. In a response to a HeadObject API call, the replication status is returned in the x-amz-replication-status element.

Note

To run HeadObject, you must have read access to the object that you're requesting. A HEAD request has the same options as a GET request, without performing a GET operation. For example, to run a HeadObject request by using the AWS Command Line Interface (AWS CLI), you can run the following command. Replace the *user input placeholders* with your own information.

```
aws s3api head-object --bucket my-bucket --key index.html
```

- After HeadObject returns the objects with a FAILED replication status, you can use S3 Batch Replication to replicate those failed objects. Alternatively, you can re-upload the failed objects to the source bucket, which will initiate replication for the new objects.
- In the replication configuration on the source bucket, verify the following:
 - The Amazon Resource Name (ARN) of the destination bucket is correct.
 - The key name prefix is correct. For example, if you set the configuration to replicate objects with the prefix Tax, then only objects with key names such as Tax/document1 or Tax/document2 are replicated. An object with the key name document3 is not replicated.
 - The status of the replication rule is Enabled.
- Verify that versioning has not been suspended on any bucket in the replication configuration. Both the source and destination buckets must have versioning enabled.
- If a replication rule is set to **Change object ownership to the destination bucket owner**, then the AWS Identity and Access Management (IAM) role that's used for replication must have the s3:ObjectOwnerOverrideToBucketOwner permission. This permission is granted on the resource (in this case, the destination bucket). For example, the following Resource statement shows how to grant this permission on the destination bucket:

```
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:ObjectOwnerOverrideToBucketOwner"]
```

```
],
"Resource":"arn:aws:s3:::DestinationBucket/*"
}
```

- If the destination bucket is owned by another account, the owner of the destination bucket must also grant the `s3:ObjectOwnerOverrideToBucketOwner` permission to the source bucket owner through the destination bucket policy. To use the following example bucket policy, replace the *user input placeholders* with your own information:

```
{
  "Version": "2012-10-17",
  "Id": "Policy1644945280205",
  "Statement": [
    {
      "Sid": "Stmt1644945277847",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789101:role/s3-replication-role"
      },
      "Action": [
        "s3:ReplicateObject",
        "s3:ReplicateTags",
        "s3:ObjectOwnerOverrideToBucketOwner"
      ],
      "Resource": "arn:aws:s3:::DestinationBucket/*"
    }
  ]
}
```

Note

If the destination bucket's object ownership settings include **Bucket owner enforced**, then you don't need to update the setting to **Change object ownership to the destination bucket owner** in the replication rule. The object ownership change will occur by default. For more information about changing replica ownership, see [Changing the replica owner](#).

- If you're setting the replication configuration in a cross-account scenario, where the source and destination buckets are owned by different AWS accounts, the destination buckets can't be

configured as Requester Pays buckets. For more information, see [Using Requester Pays buckets for storage transfers and usage](#).

- If a bucket's source objects are encrypted with an AWS Key Management Service (AWS KMS) key, then the replication rule must be configured to include AWS KMS-encrypted objects. Make sure to select **Replicate objects encrypted with AWS KMS** under your **Encryption** settings in the Amazon S3 console. Then, select an AWS KMS key for encrypting destination objects.

 **Note**

If the destination bucket is in a different account, specify an AWS KMS customer managed key that is owned by the destination account. Don't use the default Amazon S3 managed key (aws/s3). Using the default key encrypts the objects with the Amazon S3 managed key that is owned by the source account, preventing the object from being shared with another account. As a result, the destination account won't be able to access the objects in the destination bucket.

To use an AWS KMS key that belongs to the destination account to encrypt the destination objects, the destination account must grant the `kms:GenerateDataKey` and `kms:Encrypt` permissions to the replication role in the KMS key policy. To use the following example statement in your KMS key policy, replace the *user input placeholders* with your own information:

```
{  
    "Sid": "AllowS3ReplicationSourceRoleToUseTheKey",  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": "arn:aws:iam::123456789101:role/s3-replication-role"  
    },  
    "Action": ["kms:GenerateDataKey", "kms:Encrypt"],  
    "Resource": "*"  
}
```

If you use an asterisk (*) for the Resource statement in the AWS KMS key policy, the policy grants permission to use the KMS key to only the replication role. The policy doesn't allow the replication role to elevate its permissions.

By default, the KMS key policy grants the root user full permissions to the key. These permissions can be delegated to other users in the same account. Unless there are Deny statements in the source KMS key policy, using an IAM policy to grant the replication role permissions to the source KMS key is sufficient.

 **Note**

KMS key policies that restrict access to specific CIDR ranges, VPC endpoints, or S3 access points can cause replication to fail.

If either the source or destination KMS keys grant permissions based on the encryption context, confirm that Amazon S3 Bucket Keys are turned on for the buckets. If the buckets have S3 Bucket Keys turned on, the encryption context must be the bucket-level resource, like this:

```
"kms:EncryptionContext:arn:aws:arn": [
    "arn:aws:s3::::SOURCE_BUCKET_NAME"
]
"kms:EncryptionContext:arn:aws:arn": [
    "arn:aws:s3::::DESTINATION_BUCKET_NAME"
]
```

In addition to the permissions granted by the KMS key policy, the source account must add the following minimum permissions to the replication role's IAM policy:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": [
        "SourceKmsKeyArn"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey",

```

```
    "kms:Encrypt"
],
"Resource": [
    "DestinationKmsKeyArn"
]
}
```

For more information about how to replicate objects that are encrypted with AWS KMS, see [Replicating encrypted objects](#).

- If the destination bucket is owned by another AWS account, verify that the bucket owner has a bucket policy on the destination bucket that allows the source bucket owner to replicate objects. For an example, see [Configuring replication when source and destination buckets are owned by different accounts](#).
- If your objects still aren't replicating after you've validated the permissions, check for any explicit Deny statements in the following locations:
 - Deny statements in the source or destination bucket policies. Replication fails if the bucket policy denies access to the replication role for any of the following actions:

Source bucket:

```
"s3:GetReplicationConfiguration",
"s3>ListBucket",
"s3:GetObjectVersionForReplication",
"s3:GetObjectVersionAcl",
"s3:GetObjectVersionTagging"
```

Destination buckets:

```
"s3:ReplicateObject",
"s3:ReplicateDelete",
"s3:ReplicateTags"
```

- Deny statements or permissions boundaries attached to the IAM role can cause replication to fail.

- Deny statements in AWS Organizations service control policies attached to either the source or destination accounts can cause replication to fail.
- If an object replica doesn't appear in the destination bucket, the following issues might have prevented replication:
 - Amazon S3 doesn't replicate an object in a source bucket that is a replica created by another replication configuration. For example, if you set a replication configuration from bucket A to bucket B to bucket C, Amazon S3 doesn't replicate object replicas in bucket B to bucket C.
 - A source bucket owner can grant other AWS accounts permission to upload objects. By default, the source bucket owner doesn't have permissions for the objects created by other accounts. The replication configuration replicates only the objects for which the source bucket owner has access permissions. The source bucket owner can grant other AWS accounts permissions to create objects conditionally, requiring explicit access permissions on those objects. For an example policy, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control.](#)
- Suppose that in the replication configuration, you add a rule to replicate a subset of objects that have a specific tag. In this case, you must assign the specific tag key and value at the time the object is created in order for Amazon S3 to replicate the object. If you first create an object and then add the tag to the existing object, Amazon S3 doesn't replicate the object.
- Use Amazon S3 Event Notifications to notify you of instances when objects do not replicate to their destination AWS Region. Amazon S3 event notifications are available through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [Receiving replication failure events with Amazon S3 Event Notifications.](#)

You can also view replication failure reasons by using Amazon S3 Event Notifications. To review the list of failure reasons, see [Amazon S3 replication failure reasons.](#)

Batch Replication errors

To troubleshoot objects that aren't replicating to the destination bucket, check the different types of permissions for the your bucket, replication role, and IAM role that's used to create the Batch Replication job. Also, make sure to check the public access settings and bucket ownership settings.

While using Batch Replication, you might encounter one of these errors:

- Batch operation status is failed with reason: The job report could not be written to your report bucket.

This error occurs if the IAM role that's used for the Batch Operations job is unable to put the completion report into the location that was specified when you created the job. To resolve this error, check that the IAM role has PutObject permissions for the bucket where you want to save the Batch Operations completion report. It's a best practice to deliver the report to a bucket different from the source bucket.

- Batch operation is completed with failures and Total failed is not 0.

This error occurs if there are insufficient object permissions issues with the Batch Replication job that is running. If you're using a replication rule for your Batch Replication job, make sure that the IAM role used for replication has the proper permissions to access objects from either the source or destination bucket. You can also check the [Batch Replication completion report](#) to review the specific [Amazon S3 replication failure reason](#).

- Batch job ran successfully but the number of objects expected in destination bucket is not the same.

This error occurs when there's a mismatch between the objects listed in the manifest that's supplied in the Batch Replication job and the filters that you selected when you created the job. You might also receive this message when the objects in your source bucket don't match any replication rules and aren't included in the generated manifest.

Troubleshoot server access logging

The following topics can help you troubleshoot issues that you might encounter when setting up logging with Amazon S3.

Topics

- [Common error messages when setting up logging](#)
- [Troubleshooting delivery failures](#)

Common error messages when setting up logging

The following common error messages can appear when you're enabling logging through the AWS Command Line Interface (AWS CLI) and AWS SDKs:

Error: Cross S3 location logging not allowed

If the destination bucket (also known as a *target bucket*) is in a different Region than the source bucket, a Cross S3 location logging not allowed error occurs. To resolve this error, make sure that the destination bucket configured to receive the access logs is in the same AWS Region and AWS account as the source bucket.

Error: The owner for the bucket to be logged and the target bucket must be the same

When you're enabling server access logging, this error occurs if the specified destination bucket belongs to a different account. To resolve this error, make sure that the destination bucket is in the same AWS account as the source bucket.

Note

We recommend that you choose a destination bucket that's different from the source bucket. When the source bucket and destination bucket are the same, additional logs are created for the logs that are written to the bucket, which can increase your storage bill. These extra logs about logs can also make it difficult to find the particular logs that you're looking for. For simpler log management, we recommend saving access logs in a different bucket. For more information, see [the section called "How do I enable log delivery?"](#).

Error: The target bucket for logging does not exist

The destination bucket must exist prior to setting the configuration. This error indicates that the destination bucket doesn't exist or can't be found. Make sure that the bucket name is spelled correctly, and then try again.

Error: Target grants not allowed for bucket owner enforced buckets

This error indicates that the destination bucket uses the Bucket owner enforced setting for S3 Object Ownership. The Bucket owner enforced setting doesn't support destination (target) grants. For more information, see [Permissions for log delivery](#).

Troubleshooting delivery failures

To avoid server access logging issues, make sure that you're following these best practices:

- **The S3 log delivery group has write access to the destination bucket** – The S3 log delivery group delivers server access logs to the destination bucket. A bucket policy or bucket access

control list (ACL) can be used to grant write access to the destination bucket. However, we recommend that you use a bucket policy instead of an ACL. For more information about how to grant write access to your destination bucket, see [Permissions for log delivery](#).

 **Note**

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, be aware of the following:

- ACLs are disabled and no longer affect permissions. This means that you can't update your bucket ACL to grant access to the S3 log delivery group. Instead, to grant access to the logging service principal, you must update the bucket policy for the destination bucket.
- You can't include destination grants in your PutBucketLogging configuration.

- **The bucket policy for the destination bucket allows access to the logs** – Check the bucket policy of the destination bucket. Search the bucket policy for any statements that contain "Effect": "Deny". Then, verify that the Deny statement isn't preventing access logs from being written to the bucket.
- **S3 Object Lock isn't enabled on the destination bucket** – Check if the destination bucket has Object Lock enabled. Object Lock blocks server access log delivery. You must choose a destination bucket that doesn't have Object Lock enabled.
- **Amazon S3 managed keys (SSE-S3) is selected if default encryption is enabled on the destination bucket** – You can use default bucket encryption on the destination bucket only if you use server-side encryption with Amazon S3 managed keys (SSE-S3). Default server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) is not supported for server access logging destination buckets. For more information about how to enable default encryption, see [Configuring default encryption](#).
- **The destination bucket does not have Requester Pays enabled** – Using a Requester Pays bucket as the destination bucket for server access logging is not supported. To allow delivery of server access logs, disable the Requester Pays option on the destination bucket.
- **Review your AWS Organizations service control policy** – When you're using AWS Organizations, check the service control policies to make sure that Amazon S3 access is allowed. Service control policies specify the maximum permissions for the affected accounts. Search the service control policy for any statements that contain "Effect": "Deny" and verify that Deny statements aren't preventing any access logs from being written to the bucket. For more information, see [Service control policies \(SCPs\) in the AWS Organizations User Guide](#).

- **Allow some time for recent logging configuration changes to take effect** – Enabling server access logging for the first time, or changing the destination bucket for logs, requires time to fully take effect. It might take longer than an hour for all requests to be properly logged and delivered.

To check for log delivery failures, enable request metrics in Amazon CloudWatch. If the logs are not delivered within a few hours, look for the `4xxErrors` metric, which can indicate log delivery failures. For more information about enabling request metrics, see [the section called “Creating a metrics configuration for all objects”](#).

Troubleshoot versioning

The following topics can help you troubleshoot some common Amazon S3 versioning issues.

Topics

- [I want to recover objects that were accidentally deleted in a versioning-enabled bucket](#)
- [I want to permanently delete versioned objects](#)
- [I'm experiencing performance degradation after enabling bucket versioning](#)

I want to recover objects that were accidentally deleted in a versioning-enabled bucket

In general, when object versions are deleted from S3 buckets, there is no way for Amazon S3 to recover them. However, if you have enabled S3 Versioning on your S3 bucket, a DELETE request that doesn't specify a version ID cannot permanently delete an object. Instead, a delete marker is added as a placeholder. This delete marker becomes the current version of the object.

To verify whether your deleted objects are permanently deleted or temporarily deleted (with a delete marker in their place), do the following:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object.

4. In the **Objects** list, Turn on the **Show versions** toggle to the right of the search bar, and then search for the deleted object in the search bar. This toggle is available only if versioning was previously enabled on the bucket.

You can also use [S3 Inventory to search for deleted objects](#).

5. If you can't find the object after toggling **Show versions** or creating an inventory report, and you also cannot find a [delete marker](#) of the object, the deletion is permanent and the object cannot be recovered.

You can also verify a deleted object's status by using the HeadObject API operation from the AWS Command Line Interface (AWS CLI). To do so, use the following head-object command and replace the *user input placeholders* with your own information:

```
aws s3api head-object --bucket DOC-EXAMPLE-BUCKET --key index.html
```

If you run the head-object command on a versioned object whose current version is a delete marker, you will receive a 404 Not Found error. For example:

An error occurred (404) when calling the HeadObject operation: Not Found

If you run the head-object command on a versioned object and provide the object's version ID, Amazon S3 retrieves the object's metadata, confirming that the object still exists and is not permanently deleted.

```
aws s3api head-object --bucket DOC-EXAMPLE-BUCKET --key index.html --version-id versionID
```

```
{  
  "AcceptRanges": "bytes",  
  "ContentType": "text/html",  
  "LastModified": "Thu, 16 Apr 2015 18:19:14 GMT",  
  "ContentLength": 77,  
  "VersionId": "Zg5HyL7m.eZU9iM7AV1JkrqAiE.0UG4q",  
  "ETag": "\"30a6ec7e1a9ad79c203d05a589c8b400\"",  
  "Metadata": {}  
}
```

If the object is found and the newest version is a delete marker, the previous version of the object still exists. Because the delete marker is the current version of the object, you can recover the object by deleting the delete marker.

After you permanently remove the delete marker, the second newest version of the object becomes the current version of the object, making your object available once again. For a visual depiction of how objects are recovered, see [Removing delete markers](#).

To remove a specific version of an object, you must be the bucket owner. To delete a delete marker permanently, you must include its version ID in a DeleteObject request. To delete the delete marker, use the following command, and replace the *user input placeholders* with your own information:

```
aws s3api delete-object --bucket DOC-EXAMPLE-BUCKET --key index.html --version-id versionID
```

For more information about the delete-object command, see [delete-object](#) in the *AWS CLI Command Reference*. For more information about permanently deleting delete markers, see [Managing delete markers](#).

I want to permanently delete versioned objects

In a versioning-enabled bucket, a DELETE request without a version ID cannot permanently delete an object. Instead, such a request inserts a delete marker.

To permanently delete versioned objects, you can choose from the following methods:

- Create an S3 Lifecycle rule to permanently delete noncurrent versions. To permanently delete noncurrent versions, select **Permanently delete noncurrent versions of objects**, and then enter a number under **Days after objects become noncurrent**. You can optionally specify the number of newer versions to retain by entering a value under **Number of newer versions to retain**. For more information about creating this rule, see [Setting an S3 Lifecycle configuration](#).
- Delete a specified version by including the version ID in the DELETE request. For more information, see [How to delete versioned objects permanently](#).
- Create a lifecycle rule to expire current versions. To expire current versions of objects, select **Expire current versions of objects**, and then add a number under **Days after object creation**. For more information about creating this lifecycle rule, see [Setting an S3 Lifecycle configuration](#).
- To permanently delete all versioned objects and delete markers, create two lifecycle rules: one to expire current versions and permanently delete noncurrent versions of objects, and the other to delete expired object delete markers.

In a versioning-enabled bucket, a DELETE request that doesn't specify a version ID can remove only objects with a NULL version ID. If the object was uploaded when versioning was enabled, a DELETE request that doesn't specify a version ID creates a delete marker of that object.

Note

For S3 Object Lock-enabled buckets, a DELETE object request with a protected object version ID causes a 403 Access Denied error. A DELETE object request without a version ID adds a delete marker as the newest version of the object with a 200 OK response. Objects protected by Object Lock cannot be permanently deleted until their retention periods and legal holds are removed. For more information, see [the section called "How S3 Object Lock works"](#).

I'm experiencing performance degradation after enabling bucket versioning

Performance degradation can occur on versioning-enabled buckets if there are too many delete markers or versioned objects, and if best practices aren't followed.

Too many delete markers

After you enable versioning on a bucket, a DELETE request without a version ID made to an object creates a delete marker with a unique version ID. Lifecycle configurations with an **Expire current versions of objects** rule add a delete marker with a unique version ID to every object. Excessive delete markers can reduce performance in the bucket.

When versioning is suspended on a bucket, Amazon S3 marks the version ID as NULL on newly created objects. An expiration action in a versioning-suspended bucket causes Amazon S3 to create a delete marker with NULL as the version ID. In a versioning-suspended bucket, a NULL delete marker is created for any delete request. These NULL delete markers are also called expired object delete markers when all object versions are deleted and only a single delete marker remains. If too many NULL delete markers accumulate, performance degradation in the bucket occurs.

Too many versioned objects

If a versioning-enabled bucket contains objects with millions of versions, an increase in 503 Service Unavailable errors can occur. If you notice a significant increase in the number of HTTP 503 Service

Unavailable responses received for PUT or DELETE object requests to a versioning-enabled bucket, you might have one or more objects in the bucket with millions of versions. When you have objects with millions of versions, Amazon S3 automatically throttles requests to the bucket. Throttling requests protects your bucket from an excessive amount of request traffic, which could potentially impede other requests made to the same bucket.

To determine which objects have millions of versions, use S3 Inventory. S3 Inventory generates a report that provides a flat file list of the objects in a bucket. For more information, see [Amazon S3 Inventory](#).

To verify if there are high number of versioned objects in the bucket, use S3 Storage Lens metrics to view the **Current version object count**, **Noncurrent version object count**, and **Delete marker object count**. For more information about Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

The Amazon S3 team encourages customers to investigate applications that repeatedly overwrite the same object, potentially creating millions of versions for that object, to determine whether the application is working as intended. For instance, an application overwriting the same object every minute for a week can create over ten thousand versions. We recommend storing less than one hundred thousand versions for each object. If you have a use case that requires millions of versions for one or more objects, contact the AWS Support team for assistance with determining a better solution.

Best practices

To prevent versioning-related performance degradation issues, we recommend that you employ the following best practices:

- Enable a lifecycle rule to expire the previous versions of objects. For example, you can create a lifecycle rule to expire noncurrent versions after 30 days of the object being noncurrent. You can also retain multiple noncurrent versions if you don't want to delete all of them. For more information, see [Setting an S3 Lifecycle configuration](#).
- Enable a lifecycle rule to delete expired object delete markers that don't have associated data objects in the bucket. For more information, see [Removing expired object delete markers](#).

For additional Amazon S3 performance-optimization best practices, see [Best practices design patterns](#).

Getting Amazon S3 request IDs for AWS Support

Whenever you contact AWS Support because you've encountered errors or unexpected behavior in Amazon S3, you must provide the request IDs associated with the failed action. AWS Support uses these request IDs to help resolve the problems that you're experiencing.

Request IDs come in pairs, are returned in every response that Amazon S3 processes (even the erroneous ones), and can be accessed through verbose logs. There are a number of common methods for getting your request IDs, including S3 access logs and AWS CloudTrail events or data events.

After you've recovered these logs, copy and retain those two values, because you'll need them when you contact AWS Support. For information about contacting AWS Support, see [Contact AWS](#) or the [AWS Support Documentation](#).

Using HTTP to obtain request IDs

You can obtain your request IDs, `x-amz-request-id` and `x-amz-id-2` by logging the bits of an HTTP request before it reaches the target application. There are a variety of third-party tools that can be used to recover verbose logs for HTTP requests. Choose one that you trust, and then run the tool to listen on the port that your Amazon S3 traffic travels on, as you send out another Amazon S3 HTTP request.

For HTTP requests, the pair of request IDs will look like the following:

```
x-amz-request-id: 79104EXAMPLEB723  
x-amz-id-2: I0WQ4fDEXAMPLEQM+ey7N9WgVhSnQ6JEXAMPLEZb7hSQDASK+Jd1vEXAMPLEa3Km
```

Note

HTTPS requests are encrypted and hidden in most packet captures.

Using a web browser to obtain request IDs

Most web browsers have developer tools that you can use to view request headers.

For web browser-based requests that return an error, the pair of requests IDs will look like the following examples.

```
<Error><Code>AccessDenied</Code><Message>Access Denied</Message>
<RequestId>79104EXAMPLEB723</RequestId><HostId>I0WQ4fDEXAMPLEQM
+ey7N9WgVhSnQ6JEXAMPLEZb7hSQDASK+Jd1vEXAMPLEa3Km</HostId></Error>
```

To obtain the request ID pair from successful requests, use your browser's developer tools to look at the HTTP response headers. For information about developer tools for specific browsers, see *Amazon S3 Troubleshooting - How to recover your S3 request IDs* in [AWS re:Post](#).

Using the AWS SDKs to obtain request IDs

The following sections include information for configuring logging by using an AWS SDK. Although you can enable verbose logging on every request and response, we don't recommend enabling logging in production systems, because large requests or responses can significantly slow down an application.

For AWS SDK requests, the pair of request IDs will look like the following examples.

```
Status Code: 403, AWS Service: Amazon S3, AWS Request ID: 79104EXAMPLEB723
AWS Error Code: AccessDenied AWS Error Message: Access Denied
S3 Extended Request ID: I0WQ4fDEXAMPLEQM+ey7N9WgVhSnQ6JEXAMPLEZb7hSQDASK
+Jd1vEXAMPLEa3Km
```

Using the SDK for PHP to obtain request IDs

You can configure logging by using PHP. For more information, see [How can I see what data is sent over the wire?](#) in the *AWS SDK for PHP Developer Guide*.

Using the SDK for Java to obtain request IDs

You can enable logging for specific requests or responses to catch and return only the relevant headers. To do this, import the `com.amazonaws.services.s3.S3ResponseMetadata` class. Afterward, you can store the request in a variable before performing the actual request. To get the logged request or response, call `getCachedResponseMetadata(AmazonWebServiceRequest request).getRequestID()`.

Example

```
PutObjectRequest req = new PutObjectRequest(bucketName, key, createSampleFile());
```

```
s3.putObject(req);
S3ResponseMetadata md = s3.getCachedResponseMetadata(req);
System.out.println("Host ID: " + md.getHostId() + " RequestID: " + md.getRequestId());
```

Alternatively, you can use verbose logging of every Java request and response. For more information, see [Verbose Wire Logging](#) in the *AWS SDK for Java Developer Guide*.

Using the AWS SDK for .NET to obtain request IDs

You can configure logging with the AWS SDK for .NET by using the built-in `System.Diagnostics` logging tool. For more information, see the [Logging with the AWS SDK for .NET](#) *AWS Developer Blog* post.

 **Note**

By default, the returned log contains only error information. To get the request IDs, the config file must have `AWSLogMetrics` (and optionally, `AWSResponseLogging`) added.

Using the SDK for Python (Boto3) to obtain request IDs

With the AWS SDK for Python (Boto3), you can log specific responses. You can use this feature to capture only the relevant headers. The following code shows how to log parts of the response to a file:

```
import logging
import boto3
logging.basicConfig(filename='logfile.txt', level=logging.INFO)
logger = logging.getLogger(__name__)
s3 = boto3.resource('s3')
response = s3.Bucket(bucket_name).Object(object_key).put()
logger.info("HTTPStatus: %s", response['ResponseMetadata']['HTTPStatus'])
logger.info("RequestId: %s", response['ResponseMetadata']['RequestId'])
logger.info("HostId: %s", response['ResponseMetadata']['HostId'])
logger.info("Date: %s", response['ResponseMetadata']['HTTPHeaders']['date'])
```

You can also catch exceptions and log relevant information when an exception is raised. For more information, see [Discerning useful information from error responses](#) in the *AWS SDK for Python (Boto) API Reference*.

Additionally, you can configure Boto3 to output verbose debugging logs by using the following code:

```
import boto3
boto3.set_stream_logger('', logging.DEBUG)
```

For more information, see [set_stream_logger](#) in the *AWS SDK for Python (Boto) API Reference*.

Using the SDK for Ruby to obtain request IDs

You can get your request IDs using the SDK for Ruby Versions 1, 2, or 3.

- **Using the SDK for Ruby - Version 1**– You can enable HTTP wire logging globally with the following line of code.

```
s3 = AWS::S3.new(:logger => Logger.new($stdout), :http_wire_trace => true)
```

- **Using the SDK for Ruby - Version 2 or Version 3**– You can enable HTTP wire logging globally with the following line of code.

```
s3 = Aws::S3::Client.new(:logger => Logger.new($stdout), :http_wire_trace => true)
```

For tips on getting wire information from an AWS client, see [Debugging tip: Getting wire trace information from a client](#).

Using the AWS CLI to obtain request IDs

To get your request IDs when using the AWS Command Line Interface (AWS CLI), add --debug to your command.

Using Windows PowerShell to obtain request IDs

For information on recovering logs with Windows PowerShell, see the [Response Logging in AWS Tools for Windows PowerShell](#) .NET Development blog post.

Using AWS CloudTrail data events to obtain request IDs

An Amazon S3 bucket that is configured with CloudTrail data events to log S3 object-level API operations provides detailed information about actions that are taken by a user, role, or an AWS service in Amazon S3. You can [identify S3 request IDs by querying CloudTrail events with Athena](#).

Using S3 server access logging to obtain request IDs

An Amazon S3 bucket configured for S3 server access logging provides detailed records for each request that is made to the bucket. You can identify S3 request IDs by [querying the server access logs using Athena](#).

Document history

- **Current API version:** 2006-03-01

The following table describes the important changes in each release of the *Amazon Simple Storage Service API Reference* and the *Amazon S3 User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed.

Change	Description	Date
IPv6 support for S3 on Outposts	You can now access S3 on Outposts buckets using IPv6 via S3 on Outposts dual-stack endpoints. IPv6 support for S3 on Outposts allows you to manage your S3 on Outposts buckets and control plane resources over IPv6 networks.	January 16, 2024
New high-performance, single-zone Amazon S3 storage class – S3 Express One Zone	Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. For more information, see S3 Express One Zone .	November 28, 2023
Mountpoint for Amazon S3 adds support for S3 Express One Zone	You can now mount S3 Express One Zone directory buckets with Mountpoint .	November 28, 2023
Lambda invocation schema version	Amazon S3 Batch Operations introduces a new Lambda invocation schema version	November 28, 2023

	for use with Batch Operations jobs that act on directory buckets. For more information, see Using Lambda and Amazon S3 batch operations with directory buckets .	
Import action for directory buckets	Amazon S3 introduces the import action. Import is a streamlined method for creating Amazon S3 Batch Operations jobs to copy objects from general purpose buckets to directory buckets. For more information, see Importing objects into a directory bucket .	November 28, 2023
Manage S3 access with S3 Access Grants	Amazon S3 Access Grants enables you to manage data permissions at scale for AWS Identity and Access Management (IAM) principals in addition to directory identities from corporate directories such as Azure AD. You can now enforce least-privilege S3 permissions and easily scale those permissions based on your business needs. For more information, see Managing access with S3 Access Grants .	November 26, 2023
Mountpoint for Amazon S3 adds caching feature	With Mountpoint , you can now configure caching for repeatedly accessed data.	November 22, 2023

[Enhanced Amazon S3](#)[Batch Operations manifest generation](#)

You can now direct Amazon S3 Batch Operations to generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for batch replication jobs that you create in the Amazon S3 console, or for any job type that you create by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see [Creating an Amazon S3 Batch Operations job](#).

November 22, 2023

[Existing Amazon S3 buckets can now add Object Lock configurations](#)

You can now enable Object Lock on existing Amazon S3 bucket. You may set legal holds and retention periods for new or existing buckets. For more information, see [Using Object Lock](#).

November 20, 2023

[S3 Storage Lens request metrics for prefixes](#)

S3 Storage Lens introduces request metrics for prefixes within an Amazon S3 bucket. For more information, see [Metrics categories](#).

November 17, 2023

<u>Amazon S3 Storage Lens groups</u>	S3 Storage Lens introduce s Storage Lens groups, a custom defined filter for objects based on object metadata. For more information, see <u>Working with Amazon S3 Storage Lens groups.</u>	November 15, 2023
<u>New IAM policy</u>	S3 on Outposts introduce s AWSServiceRoleForS3OnOutposts , a service-linked role to help manage network resources for you. For more information, see <u>Using service-linked roles for S3 on Outposts.</u>	October 3, 2023
<u>Amazon S3 provides the Last-Modified time for delete markers</u>	Amazon S3 provides the Last-Modified time of delete markers in the response headers of S3 Head and Get API operations. For more information, see <u>Working with delete markers.</u>	September 27, 2023
<u>Amazon S3 update to AWS managed policy</u>	Amazon S3 added s3:Describe* permissions to AmazonS3ReadOnlyAccess . For more information, see <u>AWS managed policies for Amazon S3.</u>	August 11, 2023

<u>Improved start times for Standard restore requests made through S3 Batch Operations</u>	Standard retrievals for restore requests that are made through S3 Batch Operations now can start within minutes. For more information, see <u>Archive Retrieval Options</u> .	August 9, 2023
<u>Added Mountpoint, a high-throughput client for mounting an Amazon S3 bucket as a local file system.</u>	With <u>Mountpoint</u> , your applications can access objects stored in Amazon S3 through file operations, giving your applications access to the elastic storage and throughput of Amazon S3 through a file interface.	August 9, 2023
<u>Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)</u>	Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) applies two layers of encryption to objects when they are uploaded to Amazon S3. For more information, see <u>Using dual-layer server-side encryption with AWS KMS keys</u> .	June 13, 2023

[Amazon S3 enables S3 Block Public Access and disables S3 access control lists \(ACLs\) for all new buckets.](#)

Amazon S3 now automatically enables S3 Block Public Access and disables S3 access control lists (ACLs) for all new S3 buckets in all AWS Regions. For more information, see [Blocking public access to your Amazon S3 storage](#) and [Controlling ownership of objects and disabling ACLs for your bucket](#).

April 27, 2023

[S3 Replication Operations Failed metric](#)

Amazon S3 adds new Amazon CloudWatch metric to monitor S3 Replication failures. For more information, see [Monitoring progress with replication metrics](#).

April 5, 2023

[Private DNS](#)

AWS PrivateLink for Amazon S3 now supports Private DNS. For more information, see [Private DNS](#).

March 14, 2023

[Cross-account access points support in the Amazon S3 console](#)

Amazon S3 now supports creating cross-account access points with the Amazon S3 console. For more information, see [Creating access points](#).

March 14, 2023

<u>Amazon S3 on Outposts supports S3 Replication on Outposts</u>	With local S3 Replicati on, you can automatically replicate objects to a single Outposts destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Outposts or within the same Outposts as the source bucket. For more information, see <u>Replicating objects for S3 on Outposts</u> .	March 14, 2023
<u>Amazon S3 Object Lambda Access Point alias</u>	When you create an Object Lambda Access Point, Amazon S3 automatically generates a unique alias for your Object Lambda Access Point. You can use this alias instead of an Amazon S3 bucket name or the Object Lambda Access Point Amazon Resource Name (ARN) in a request for access point data plane operations. For more information, see <u>How to use a bucket-style alias for your Object Lambda Access Point</u> .	March 14, 2023
<u>Amazon S3 Multi-Region Access Points cross-account support</u>	Amazon S3 now supports creating cross-account Multi-Region Access Points with the Amazon S3 console. For more information, see <u>Creating Multi-Region Access Points</u> .	March 14, 2023

<u>Cross-account access points</u>	Amazon S3 supports creating cross-account access points. You can create a cross-account access point by using the AWS Command Line Interface (AWS CLI) or the REST API <code>CreateAccessPoint</code> operation. For more information, see <u>Creating access points</u> .	November 30, 2022
<u>Amazon S3 supports failover controls for Amazon S3 Multi-Region Access Points</u>	Amazon S3 introduces failover control for Multi-Region Access Points. These controls let you shift S3 data access request traffic routed through an Amazon S3 Multi-Region Access Point to an alternate AWS Region within minutes to test and build highly available applications. For more information, see <u>Amazon S3 Multi-Region Access Point failover controls</u> .	November 28, 2022
<u>Amazon S3 Storage Lens increases organization-wide visibility with 34 new metrics</u>	S3 Storage Lens introduces 34 additional metrics to uncover deeper cost-optimization opportunities, identify data-protection best practices, and improve the performance of application workflows. For more information, see <u>S3 Storage Lens metrics</u> .	November 17, 2022

<u>Amazon S3 supports higher restore request rates for S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive</u>	Amazon S3 supports restore requests at a rate of up to 1,000 transactions per second, per AWS account for the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.	November 15, 2022
<u>Amazon S3 on Outposts supports additional S3 Lifecycle actions and filters</u>	S3 on Outposts supports additional S3 Lifecycle rules to optimize capacity management. You can expire objects as they age or are replaced with newer versions. You can create a lifecycle rule for a whole bucket or a subset of objects in a bucket by filtering with prefixes, object tags, or object size. For more information, see <u>Creating and managing a lifecycle configuration</u> .	November 2, 2022
<u>S3 Replication support for SSE-C objects</u>	You can replicate objects that are created using server-side encryption with customer-provided keys. For more information about replicating encrypted objects, see <u>Replicating objects created with server-side encryption (SSE-C, SSE-S3, SSE-KMS)</u> .	October 24, 2022

[Amazon S3 on Outposts supports access point aliases](#)

With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Every time you create an access point for a bucket, S3 on Outposts automatically generates an access point alias. You can use this access point alias instead of an access point ARN for any data plane operation. For more information, see [Using a bucket-style alias for your S3 on Outposts bucket access point](#).

[S3 Object Lambda supports the HeadObject , ListObjects , and ListObjectsV2 operations](#)

You can use custom code to modify the data returned by standard S3 GET, LIST, or HEAD requests to filter rows, dynamically resize images, redact confidential data, and more. For more information, see [Transforming objects with S3 Object Lambda](#).

October 21, 2022

October 4, 2022

[Amazon S3 on Outposts supports S3 Versioning](#)

When enabled, S3 Versioning saves multiple distinct copies of an object in the same bucket. You can use S3 Versioning to preserve, retrieve, and restore every version of every object stored in your Outposts buckets. S3 Versioning helps you recover from unintended user actions and application failures. For more information, see [Managing S3 Versioning for your S3 on Outposts bucket](#).

September 21, 2022

[AWS Backup for Amazon S3](#)

AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more information, see [Using AWS Backup for Amazon S3](#).

February 18, 2022

[Use S3 Batch Replication to replicate existing objects](#)

With S3 Batch Replication, you can replicate objects that existed before a replication configuration was in place. Replicating existing objects is done through the use of a Batch Operations job. S3 Batch Replication differs from live replication, which continuously and automatically copies new objects across Amazon S3 buckets. For more information, see [Replicating existing objects with S3 Batch Replication](#).

[Rename of S3 Glacier Flexible Retrieval](#)

The Glacier storage class has been renamed to S3 Glacier Flexible Retrieval. This change does not impact the API.

February 8, 2022

November 30, 2021

<u>New S3 Object Ownership setting to disable ACLs</u>	You can apply the bucket owner enforced setting for Object Ownership to disable ACLs for your bucket and the objects in it and take ownership of every object in your bucket. The bucket owner enforced setting simplifies access management for data stored in Amazon S3. For more information, see <u>Controlling ownership of objects and disabling ACLs for your bucket.</u>	November 30, 2021
<u>New S3 Intelligent-Tiering storage class</u>	S3 Intelligent-Tiering Archive Instant Access is an additional storage class under S3 Intelligent-Tiering. For more information, see <u>How S3 Intelligent-Tiering works.</u>	November 30, 2021
<u>New S3 Glacier Instant Retrieval storage class</u>	You can now place objects in the S3 Glacier Instant Retrieval storage class. For more information about this storage class, see <u>Using Amazon S3 storage classes.</u>	November 30, 2021

<u>AWS Backup for Amazon S3</u> <u>Preview</u>	AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more information see, <u>Using AWS Backup for Amazon S3</u> .	November 30, 2021
<u>AWS Identity and Access Management Access Analyzer for Amazon S3</u>	IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. To learn more about validating policies using IAM Access Analyzer, see <u>IAM Access Analyzer policy validation</u> in the <i>IAM User Guide</i> .	November 30, 2021
<u>New event types</u>	New event types added to Amazon S3 Event Notifications, see <u>Amazon S3 Event Notifications</u> .	November 29, 2021
<u>Enable Amazon EventBridge on buckets</u>	You can enable EventBridge on Amazon S3 buckets to send events to Amazon EventBridge, see <u>Using EventBridge</u> .	November 29, 2021
<u>New S3 Lifecycle filters</u>	You can create lifecycle rules based on object size or specify how many noncurrent object versions to keep. For more information, see <u>Examples of S3 Lifecycle configuration</u> .	November 23, 2021

[Publish Amazon S3 Storage](#)

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, like alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, the CloudWatch APIs enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information, see the [Monitor S3 Storage Lens metrics in CloudWatch](#).

November 22, 2021

[Lens metrics to Amazon CloudWatch](#)

You can use Multi-Region Access Points to create a global endpoint that applications can use to fulfill requests from Amazon S3 buckets located in multiple AWS Regions. You can use this Multi-Region Access Point to route data to a bucket with the lowest latency. For more information about Multi-Region Access Points and how to use them, see [Multi-Region Access Point in Amazon S3](#).

September 2, 2021

[Amazon S3 on Outposts adds direct local access for applications](#)

Run your applications outside the AWS Outposts virtual private cloud (VPC) and access your S3 on Outposts data. You can also access S3 on Outposts objects directly from your on-premises network. For more information about configuring S3 on Outposts endpoints using [customer-owned IP \(CoIP\) addresses](#) and accessing your objects by creating a [local gateway](#) from your on-premises network, see [Accessing Amazon S3 on Outposts using VPC-only access points](#).

July 29, 2021

[Amazon S3 access point alias](#)

When you create an access point, Amazon S3 automatically generates an alias that you can use instead of a bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for any access point data plane operation. For more information, see [Using a bucket-style alias for your access point](#).

July 26, 2021

<u>Amazon S3 Inventory and S3 Batch Operations support S3</u>	Amazon S3 Inventory and Batch Operations support identifying and copying existing objects with S3 Bucket Keys. S3 Bucket Keys accelerate the reduction of server-side encryption costs for existing objects. For more information, see <u>Amazon S3 Inventory and Batch Operations Copy object</u> .	June 3, 2021
<u>Amazon S3 Storage Lens metrics account snapshot</u>	The S3 Storage Lens account snapshot displays your total storage, object count, and average object size on the S3 console home (Buckets) page by summarizing metrics from your default dashboard. For more information, see <u>S3 Storage Lens metrics account snapshot</u> .	May 5, 2021
<u>Increased Amazon S3 on Outposts endpoint support</u>	S3 on Outposts now supports up to 100 endpoints per Outpost. For more information, see <u>S3 on Outposts network restrictions</u> .	April 29, 2021

<u>Amazon S3 on Outposts event notifications in Amazon CloudWatch Events</u>	You can use CloudWatch Events to create a rule to capture any S3 on Outposts API event and get notified through all supported CloudWatch targets. For more information, see <u>Receiving S3 on Outposts event notifications using CloudWatch Events.</u>	April 19, 2021
<u>S3 Object Lambda</u>	With S3 Object Lambda, you can add your own code to Amazon S3 GET requests to modify and process data as it is returned to an application. You can use custom code to modify the data returned by standard S3 GET requests to filter rows, dynamically resize images, redact confidential data, and more. For more information, see <u>Transforming objects.</u>	March 18, 2021

AWS PrivateLink

With AWS PrivateLink for Amazon S3, you can connect directly to S3 by using an interface endpoint in your virtual private cloud (VPC) instead of connecting over the internet. Interface endpoints are directly accessible from applications that are on premises or in a different AWS Region. For more information, see [AWS PrivateLink for Amazon S3](#).

February 2, 2021

Managing Amazon S3 on Outposts capacity with AWS CloudTrail

S3 on Outposts management events are available through CloudTrail logs. For more information, see [Managing S3 on Outposts capacity with CloudTrail](#).

December 21, 2020

Strong consistency

Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your S3 bucket in all AWS Regions. In addition, read operations on Amazon S3 Select, Amazon S3 access control lists, Amazon S3 Object Tags, and object metadata (for example, HEAD object) are strongly consistent. For more information, see [Amazon S3 data consistency model](#).

December 1, 2020

<u>Amazon S3 replica modification sync</u>	Amazon S3 replica modification sync keeps object metadata, such as tags, ACLs, and Object Lock settings, in sync between source objects and replicas. When this feature is enabled, Amazon S3 replicates metadata changes made to either the source object or the replica copies. For more information, see <u>Replicating metadata changes with replica modification sync.</u>	December 1, 2020
<u>Amazon S3 Bucket Keys</u>	Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (SSE-KMS). This new bucket-level key for server-side encryption can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see <u>Reducing the cost of SSE-KMS by using S3 Bucket Keys.</u>	December 1, 2020

<u>Amazon S3 Storage Lens</u>	S3 Storage Lens aggregate your metrics and displays the information in the Account snapshot section on the Amazon S3 console Buckets page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket. For more information, see <u>Assessing your storage activity and usage with S3 Storage Lens</u> .	November 18, 2020
<u>Tracing S3 requests using AWS X-Ray</u>	Amazon S3 integrates with X-Ray to propagate the <u>trace context</u> and give you one request chain with <u>upstream and downstream</u> nodes. For more information, see <u>Tracing requests using X-Ray</u> .	November 16, 2020

[S3 Replication metrics](#)

S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. For more information, see [Replication metrics and Amazon S3 event notifications](#).

November 9, 2020

[S3 Intelligent-Tiering Archive Access and Deep Archive Access](#)

S3 Intelligent-Tiering Archive Access and Deep Archive Access are additional storage tiers under S3 Intelligent-Tiering. For more information, see [Storage class for automatically optimizing frequently and infrequently accessed objects](#).

November 9, 2020

[Delete marker replication](#)

With delete marker replication, you can ensure that delete markers are copied to your destination buckets for your replication rules. For more information, see [Using delete marker replication](#).

November 9, 2020

[S3 Object Ownership](#)

Object Ownership is an S3 bucket setting that you can use to control ownership of new objects that are uploaded to your buckets. For more information, see [Using S3 Object Ownership](#).

October 2, 2020

[Amazon S3 on Outposts](#)

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and easily store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API. For more information, see [Using Amazon S3 on Outposts](#).

September 30, 2020

[Bucket owner condition](#)

You can use the Amazon S3 bucket owner condition to ensure that the buckets you use in your S3 operations belong to the AWS accounts that you expect. For more information, see [Bucket owner condition](#).

September 11, 2020

[S3 Batch Operations support for Object Lock Retention](#)

You can now use Batch Operations with S3 Object Lock to apply retention settings to many Amazon S3 objects at once. For more information, see [Setting S3 Object Lock Retention dates with S3 Batch Operations](#).

May 4, 2020

<u>S3 Batch Operations support for Object Lock Legal Hold</u>	You can now use Batch Operations with S3 Object Lock to add a legal hold to many Amazon S3 objects at once. For more information, see <u>Using S3 Batch Operations for setting S3 Object Lock Legal Hold.</u>	May 4, 2020
<u>Job tags for S3 Batch Operations</u>	You can add tags to your S3 Batch Operations jobs to control and label those jobs. For more information, see <u>Tags for S3 Batch Operations jobs.</u>	March 16, 2020
<u>Amazon S3 access points</u>	Amazon S3 access points simplify managing data access at scale for shared datasets in S3. Access points are named network endpoints that are attached to buckets that you can use to perform S3 object operations. For more information, see <u>Managing data access with Amazon S3 access points.</u>	December 2, 2019

<u>Access Analyzer for Amazon S3</u>	Access Analyzer for Amazon S3 alerts you to S3 buckets that are configured to allow access to anyone on the internet or other AWS accounts, including accounts outside of your organization. For more information, see <u>Using Access Analyzer for Amazon S3</u> .	December 2, 2019
<u>S3 Replication Time Control (S3 RTC)</u>	S3 Replication Time Control (S3 RTC) replicates most objects that you upload to Amazon S3 in seconds, and 99.99 percent of those objects within 15 minutes. For more information, see <u>Replicating objects using S3 Replication Time Control (S3 RTC)</u> .	November 20, 2019
<u>Same-Region Replication</u>	You can use Same-Region Replication (SRR) to copy objects across Amazon S3 buckets in the same AWS Region. For information about both Cross-Region Replication (CRR) and Same-Region Replication, see <u>Replication</u> .	September 18, 2019
<u>Cross-Region Replication support for S3 Object Lock</u>	Cross-Region Replication now supports Object Lock. For more information, see <u>What does Amazon S3 Replicate?</u> .	May 28, 2019

[S3 Batch Operations](#)

By using S3 Batch Operations, you can perform large-scale Batch Operations on Amazon S3 objects. S3 Batch Operations can run a single operation on lists of objects that you specify. A single job can perform the specified operation on billions of objects containing exabytes of data. For more information, see [Performing S3 Batch Operations](#).

April 30, 2019

[Asia Pacific \(Hong Kong\) Region](#)

Amazon S3 is now available in the Asia Pacific (Hong Kong) Region. For more information about Amazon S3 Regions and endpoints, see [Regions and endpoints](#) in the *AWS General Reference*.

April 24, 2019

[Added a new field to the server access logs](#)

Amazon S3 added the following new field to the server access logs: Transport Layer Security (TLS) version. For more information, see [Server access log format](#).

March 28, 2019

[New archive storage class](#)

Amazon S3 now offers a new archive storage class, S3 Glacier Deep Archive (DEEP_ARCHIVE), for storing rarely accessed objects. For more information, see [Storage Classes](#).

March 27, 2019

<u>Added new fields to the server access logs</u>	Amazon S3 added the following new fields to the server access logs: Host Id, Signature Version, Cipher Suite, Authentication Type, and Host Header. For more information, see <u>Server access log format</u> .	March 5, 2019
<u>Support for Parquet-formatted Amazon S3 Inventory files</u>	Amazon S3 now supports the <u>Apache Parquet (Parquet)</u> format in addition to the <u>Apache optimized row columnar (ORC)</u> and comma-separated values (CSV) file formats for inventory output files. For more information, see <u>Inventory</u> .	December 4, 2018
<u>S3 Object Lock</u>	Amazon S3 now offers Object Lock functionality that provides Write Once Read Many (WORM) protections for Amazon S3 objects. For more information, see <u>Locking Objects</u> .	November 26, 2018
<u>Restore speed upgrade</u>	Using Amazon S3 restore speed upgrade, you can change the speed of a restoration from the S3 Glacier Flexible Retrieval storage class to a faster speed while the restoration is in progress. For more information, see <u>Restoring Archived Objects</u> .	November 26, 2018

Restore Event Notifications

Amazon S3 Event Notifications now support initiation and completion events when restoring objects from the S3 Glacier Flexible Retrieval storage class. For more information, see [Event Notifications](#).

November 26, 2018

[PUT directly to the S3 Glacier Flexible Retrieval storage class](#)

The Amazon S3 PUT operation now supports specifying S3 Glacier Flexible Retrieval as the storage class when creating objects. Previously, you had to transition objects to the S3 Glacier Flexible Retrieval storage class from another Amazon S3 storage class. Also, when using S3 Cross-Region Replication (CRR), you can now specify S3 Glacier Flexible Retrieval as the storage class for replicated objects. For more information about the S3 Glacier Flexible Retrieval storage class, see [Storage Classes](#). For more information about specifying the storage class for replicated objects, [Replication Configuration Overview](#). For more information about the direct PUT to S3 Glacier Flexible Retrieval REST API changes, see [Document History: PUT directly to S3 Glacier Flexible Retrieval](#).

November 26, 2018

<u>New storage class</u>	Amazon S3 now offers a new storage class named S3 Intelligent-Tiering (INTELLIGENT_TIERING) that is designed for long-lived data with changing or unknown access patterns. For more information, see <u>Storage Classes</u> .	November 26, 2018
<u>Amazon S3 Block Public Access</u>	Amazon S3 now includes the ability to block public access to buckets and objects on a per-bucket or account-wide basis. For more information, see <u>Using Amazon S3 Block Public Access</u> .	November 15, 2018
<u>Filtering enhancements in Cross-Region Replication (CRR) rules</u>	In a CRR rule configuration, you can specify an object filter to choose a subset of objects to apply the rule to. Previously, you could filter only on an object key prefix. In this release, you can filter on an object key prefix, one or more object tags, or both. For more information, see <u>CRR Setup: Replication Configuration Overview</u> .	September 19, 2018

<u>New Amazon S3 Select features</u>	Amazon S3 Select now supports Apache Parquet input, queries on nested JSON objects, and two new Amazon CloudWatch monitoring metrics (<code>SelectScannedBytes</code> and <code>SelectReturnedBytes</code>).	September 5, 2018
<u>Updates now available over RSS</u>	You can now subscribe to an RSS feed to receive notifications about updates to the <i>Amazon S3 User Guide</i> .	June 19, 2018

Earlier updates

The following table describes the important changes in each release of the *Amazon S3 User Guide* before June 19, 2018.

Change	Description	Date
Code examples update	<p>Code examples updated:</p> <ul style="list-style-type: none">• C#—Updated all of the examples to use the task-based asynchronous pattern. For more information, see Amazon Web Services Asynchronous APIs for .NET in the <i>AWS SDK for .NET Developer Guide</i>. Code examples are now compliant with version 3 of the AWS SDK for .NET.• Java—Updated all of the examples to use the client builder model. For more information about the client builder model, see Creating Service Clients.•	April 30, 2018

Change	Description	Date
	<p>PHP—Updated all of the examples to use the AWS SDK for PHP 3.0. For more information about the AWS SDK for PHP 3.0, see AWS SDK for PHP.</p> <ul style="list-style-type: none">Ruby—Updated example code so that the examples work with the AWS SDK for Ruby version 3.	
Amazon S3 now reports S3 Glacier Flexible Retrieval and ONEZONE_IA storage classes to Amazon CloudWatch Logs storage metrics	<p>In addition to reporting actual bytes, these storage metrics include per-object overhead bytes for applicable storage classes (ONEZONE_IA, STANDARD_IA, and S3 Glacier Flexible Retrieval):</p> <ul style="list-style-type: none">For ONEZONE_IA and STANDARD_IA storage class objects, Amazon S3 reports objects smaller than 128 KB as 128 KB. For more information, see Using Amazon S3 storage classes.For S3 Glacier Flexible Retrieval storage class objects, the storage metrics report the following overheads:<ul style="list-style-type: none">A 32 KB per-object overhead, charged at S3 Glacier Flexible Retrieval storage class pricingAn 8 KB per-object overhead, charged at STANDARD storage class pricing <p>For more information, see Transitioning objects using Amazon S3 Lifecycle.</p> <p>For more information about storage metrics, see Monitoring metrics with Amazon CloudWatch.</p>	April 30, 2018

Change	Description	Date
New storage class	<p>Amazon S3 now offers a new storage class, STANDARD_IA (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Using Amazon S3 storage classes.</p>	April 4, 2018
Amazon S3 Select	<p>Amazon S3 now supports retrieving object content based on an SQL expression. For more information, see Filtering and retrieving data using Amazon S3 Select.</p>	April 4, 2018
Asia Pacific (Osaka-Local) Region	<p>Amazon S3 is now available in the Asia Pacific (Osaka-Local) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i>.</p>	February 12, 2018
	⚠ Important <p>You can use the Asia Pacific (Osaka-Local) Region only in conjunction with the Asia Pacific (Tokyo) Region. To request access to Asia Pacific (Osaka-Local) Region, contact your sales representative.</p>	
Amazon S3 Inventory creation timestamp	<p>Amazon S3 Inventory now includes a timestamp of the date and start time of the creation of the Amazon S3 Inventory report. You can use the timestamp to determine changes in your Amazon S3 storage from the start time of when the inventory report was generated.</p>	January 16, 2018
Europe (Paris) Region	<p>Amazon S3 is now available in the Europe (Paris) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i>.</p>	December 18, 2017

Change	Description	Date
China (Ningxia) Region	Amazon S3 is now available in the China (Ningxia) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	November 29, 2017
Support for ORC-formatted Amazon S3 Inventory files	Amazon S3 now supports the Apache optimized row columnar (ORC) format in addition to comma-separated values (CSV) file format for inventory output files. Also, you can now query Amazon S3 inventory using standard SQL by using Amazon Athena, Amazon Redshift Spectrum, and other tools such as Presto , Apache Hive , and Apache Spark . For more information, see Amazon S3 Inventory .	November 17, 2017
Default encryption for S3 buckets	Amazon S3 default encryption provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The objects are encrypted using server-side encryption with either Amazon S3 managed keys (SSE-S3) or AWS managed keys (SSE-KMS). For more information, see Setting default server-side encryption behavior for Amazon S3 buckets .	November 06, 2017
Encryption status in Amazon S3 Inventory	Amazon S3 now supports including encryption status in Amazon S3 Inventory so you can see how your objects are encrypted at rest for compliance auditing or other purposes. You can also configure to encrypt Amazon S3 Inventory with server-side encryption (SSE) or SSE-KMS so that all inventory files are encrypted accordingly. For more information, see Amazon S3 Inventory .	November 06, 2017

Change	Description	Date
Cross-Region Replication (CRR) enhancements	<p>Cross-Region Replication now supports the following:</p> <ul style="list-style-type: none">• In a cross-account scenario, you can add a CRR configuration to change replica ownership to the AWS account that owns the destination bucket. For more information, see Changing the replica owner.• By default, Amazon S3 does not replicate objects in your source bucket that are created using server-side encryption using keys stored in AWS KMS. In your CRR configuration, you can now direct Amazon S3 to replicate these objects. For more information, see Replicating objects created with server-side encryption (SSE-C, SSE-S3, SSE-KMS, DSSE-KMS).	November 06, 2017
Europe (London) Region	Amazon S3 is now available in the Europe (London) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	December 13, 2016
Canada (Central) Region	Amazon S3 is now available in the Canada (Central) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	December 8, 2016

Change	Description	Date
Object tagging	<p>Amazon S3 now supports object tagging. Object tagging enables you to categorize storage. Object key name prefixes also enable you to categorize storage, object tagging adds another dimension to it.</p> <p>There are added benefits tagging offers. These include:</p> <ul style="list-style-type: none"> • Object tags enable fine-grained access control of permissions (for example, you could grant an IAM user permissions to read-only objects with specific tags). • Fine-grained control in specifying lifecycle configuration. You can specify tags to select a subset of objects to which lifecycle rule applies. • If you have Cross-Region Replication (CRR) configured, Amazon S3 can replicate the tags. You must grant necessary permission to the IAM role created for Amazon S3 to assume to replicate objects on your behalf. • You can also customize CloudWatch metrics and CloudTrail events to display information by specific tag filters. <p>For more information, see Categorizing your storage using tags.</p>	November 29, 2016
Amazon S3 Lifecycle now supports tag-based filters	Amazon S3 now supports tag-based filtering in lifecycle configuration. You can now specify lifecycle rules in which you can specify a key prefix, one or more object tags, or a combination of both to select a subset of objects to which the lifecycle rule applies. For more information, see Managing your storage lifecycle .	November 29, 2016

Change	Description	Date
CloudWatch request metrics for buckets	<p>Amazon S3 now supports CloudWatch metrics for requests made on buckets. When you enable these metrics for a bucket, the metrics report at 1-minute intervals. You can also configure which objects in a bucket will report these request metrics. For more information, see Monitoring metrics with Amazon CloudWatch.</p>	November 29, 2016
Amazon S3 Inventory	<p>Amazon S3 now supports storage inventory. Amazon S3 Inventory provides a flat-file output of your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or a shared prefix (that is, objects that have names that begin with a common string).</p> <p>For more information, see Amazon S3 Inventory.</p>	November 29, 2016
Amazon S3 Analytics – Storage Class Analysis	<p>The new Amazon S3 analytics – storage class analysis feature observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. This feature also includes a detailed daily analysis of your storage usage at the specified bucket, prefix, or tag level that you can export to an S3 bucket.</p>	November 29, 2016
New Expedited and Bulk data retrievals when restoring archived objects from S3 Glacier	<p>Amazon S3 now supports Expedited and Bulk data retrievals in addition to Standard retrievals when restoring objects archived to S3 Glacier. For more information, see Restoring an archived object.</p>	November 21, 2016

Change	Description	Date
CloudTrail object logging	CloudTrail supports logging Amazon S3 object level API operations such as <code>GetObject</code> , <code>PutObject</code> , and <code>DeleteObject</code> . You can configure your event selectors to log object level API operations. For more information, see Logging Amazon S3 API calls using AWS CloudTrail .	November 21, 2016
US East (Ohio) Region	Amazon S3 is now available in the US East (Ohio) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	October 17, 2016
IPv6 support for Amazon S3 Transfer Acceleration	Amazon S3 now supports Internet Protocol version 6 (IPv6) for Amazon S3 Transfer Acceleration. You can connect to Amazon S3 over IPv6 by using the new dual-stack for Transfer Acceleration endpoint. For more information, see Getting started with Amazon S3 Transfer Acceleration .	October 6, 2016
IPv6 support	Amazon S3 now supports Internet Protocol version 6 (IPv6). You can access Amazon S3 over IPv6 by using dual-stack endpoints. For more information, see Making requests to Amazon S3 over IPv6 .	August 11, 2016
Asia Pacific (Mumbai) Region	Amazon S3 is now available in the Asia Pacific (Mumbai) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	June 27, 2016
Amazon S3 Transfer Acceleration	<p>Amazon S3 Transfer Acceleration enables fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration takes advantage of Amazon CloudFront globally distributed edge locations.</p> <p>For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.</p>	April 19, 2016

Change	Description	Date
Lifecycle support to remove expired object delete markers	Lifecycle configuration Expiration action now allows you to direct Amazon S3 to remove expired object delete markers in a/ versioned bucket. For more information, see Elements to describe lifecycle actions .	March 16, 2016

Change	Description	Date
Bucket lifecycle configuration now supports action to stop incomplete multipart uploads	<p>Bucket lifecycle configuration now supports the <code>AbortIncompleteMultipartUpload</code> action that you can use to direct Amazon S3 to stop multipart uploads that don't complete within a specified number of days after being initiated. When a multipart upload becomes eligible for a stop operation, Amazon S3 deletes any uploaded parts and stops the multipart upload.</p> <p>For conceptual information, see the following topics in the <i>Amazon S3 User Guide</i>:</p> <ul style="list-style-type: none">• Aborting a multipart upload• Elements to describe lifecycle actions <p>The following API operations have been updated to support the new action:</p> <ul style="list-style-type: none">• PUT Bucket lifecycle – The XML configuration now allows you to specify the <code>AbortIncompleteMultipartUpload</code> action in a lifecycle configuration rule.• List Parts and Initiate Multipart Upload – Both of these API operations now return two additional response headers (<code>x-amz-abort-date</code>, and <code>x-amz-abort-rule-id</code>) if the bucket has a lifecycle rule that specifies the <code>AbortIncompleteMultipartUpload</code> action. These headers in the response indicate when the initiated multipart upload becomes eligible for a stop operation and which lifecycle rule is applicable.	March 16, 2016

Change	Description	Date
Asia Pacific (Seoul) Region	<p>Amazon S3 is now available in the Asia Pacific (Seoul) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i>.</p>	January 6, 2016
New condition key and a multipart upload change	<p>IAM policies now support an Amazon S3 <code>s3:x-amz-storage-class</code> condition key. For more information, see Amazon S3 condition key examples.</p> <p>You no longer need to be the initiator of a multipart upload to upload parts and complete the upload. For more information, see Multipart upload API and permissions.</p>	December 14, 2015
Renamed the US Standard Region	<p>Changed the Region name string from "US Standard" to "US East (N. Virginia)." This is only a Region name update, there is no change in the functionality.</p>	December 11, 2015
New storage class	<p>Amazon S3 now offers a new storage class, STANDARD_IA (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Using Amazon S3 storage classes.</p> <p>Lifecycle configuration feature updates now allow you to transition objects to the STANDARD_IA storage class. For more information, see Managing your storage lifecycle.</p> <p>Previously, the Cross-Region Replication feature used the storage class of the source object for object replicas. Now, when you configure Cross-Region Replication, you can specify a storage class for the object replica created in the destination bucket. For more information, see Replicating objects.</p>	September 16, 2015

Change	Description	Date
AWS CloudTrail integration	<p>New AWS CloudTrail integration allows you to record Amazon S3 API activity in your S3 bucket. You can use CloudTrail to track S3 bucket creations or deletions, access control modifications, or lifecycle configuration changes. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.</p>	September 1, 2015
Bucket limit increase	<p>Amazon S3 now supports bucket limit increases. By default, customers can create up to 100 buckets in their AWS account. Customers who need additional buckets can increase that limit by submitting a service limit increase. For information about how to increase your bucket limit, go to AWS service quotas in the AWS <i>General Reference</i>. For more information, see Using the AWS SDKs and Bucket restrictions and limitations.</p>	August 4, 2015
Consistency model update	<p>Amazon S3 now supports read-after-write consistency for new objects added to Amazon S3 in the US East (N. Virginia) Region. Prior to this update, all Regions except US East (N. Virginia) Region supported read-after-write consistency for new objects uploaded to Amazon S3. With this enhancement, Amazon S3 now supports read-after-write consistency in all Regions for new objects added to Amazon S3. Read-after-write consistency allows you to retrieve objects immediately after creation in Amazon S3. For more information, see Regions.</p>	August 4, 2015
Event notifications	<p>Amazon S3 Event Notifications have been updated to add notifications when objects are deleted and to add filtering on object names with prefix and suffix matching. For more information, see Amazon S3 Event Notifications.</p>	July 28, 2015

Change	Description	Date
Amazon CloudWatch integration	New Amazon CloudWatch integration allows you to monitor and set alarms on your Amazon S3 usage through CloudWatch metrics for Amazon S3. Supported metrics include total bytes for Standard storage, total bytes for Reduced-Redundancy Storage, and total number of objects for a given S3 bucket. For more information, see Monitoring metrics with Amazon CloudWatch .	July 28, 2015
Support for deleting and emptying non-empty buckets	Amazon S3 now supports deleting and emptying non-empty buckets. For more information, see Emptying a bucket .	July 16, 2015
Bucket policies for Amazon VPC endpoints	Amazon S3 has added support for bucket policies for virtual private cloud (VPC) (VPC) endpoints. You can use S3 bucket policies to control access to buckets from specific VPC endpoints, or specific VPCs. VPC endpoints are easy to configure, are highly reliable, and provide a secure connection to Amazon S3 without requiring a gateway or a NAT instance. For more information, see Controlling access from VPC endpoints with bucket policies .	April 29, 2015
Event notifications	Amazon S3 Event Notifications have been updated to support the switch to resource-based permissions for AWS Lambda functions. For more information, see Amazon S3 Event Notifications .	April 9, 2015
Cross-Region Replication	Amazon S3 now supports Cross-Region Replication. Cross-Region Replication is the automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see Replicating objects .	March 24, 2015

Change	Description	Date
Event notifications	<p>Amazon S3 now supports new event types and destinations in a bucket notification configuration. Prior to this release, Amazon S3 supported only the <code>s3:ReducedRedundancyLostObject</code> event type and an Amazon SNS topic as the destination. For more information about the new event types, see Amazon S3 Event Notifications.</p>	November 13, 2014
Server-side encryption with customer-provided encryption keys	<p>Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)</p> <p>Amazon S3 now supports server-side encryption using AWS KMS. This feature allows you to manage the envelope key through AWS KMS, and Amazon S3 calls AWS KMS to access the envelope key within the permissions you set.</p> <p>For more information about server-side encryption with AWS KMS, see Protecting Data Using Server-Side Encryption with AWS Key Management Service.</p>	November 12, 2014
Europe (Frankfurt) Region	Amazon S3 is now available in the Europe (Frankfurt) Region.	October 23, 2014
Server-side encryption with customer-provided encryption keys	<p>Amazon S3 now supports server-side encryption using customer-provided encryption keys (SSE-C). Server-side encryption enables you to request Amazon S3 to encrypt your data at rest. When using SSE-C, Amazon S3 encrypts your objects with the custom encryption keys that you provide. Since Amazon S3 performs the encryption for you, you get the benefits of using your own encryption keys without the cost of writing or executing your own encryption code.</p> <p>For more information about SSE-C, see Server-Side Encryption (Using Customer-Provided Encryption Keys).</p>	June 12, 2014

Change	Description	Date
Lifecycle support for versioning	Prior to this release, lifecycle configuration was supported only on nonversioned buckets. Now you can configure lifecycle on both nonversioned and versioning-enabled buckets. For more information, see Managing your storage lifecycle .	May 20, 2014
Access control topics revised	Revised Amazon S3 access control documentation. For more information, see Identity and access management in Amazon S3 .	April 15, 2014
Server access logging topic revised	Revised server access logging documentation. For more information, see Logging requests with server access logging .	November 26, 2013
.NET SDK samples updated to version 2.0	.NET SDK samples in this guide are now compliant to version 2.0.	November 26, 2013
SOAP Support Over HTTP deprecated	SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features will not be supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.	September 20, 2013
IAM policy variable support	<p>IAM policy language now supports variables. When a policy is evaluated, any policy variables are replaced with values that are supplied by context-based information from the authenticated user's session. You can use policy variables to define general purpose policies without explicitly listing all the components of the policy. For more information about policy variables, see IAM Policy Variables Overview in the <i>IAM User Guide</i>.</p> <p>For examples of policy variables in Amazon S3, see User and role policy examples.</p>	April 3, 2013

Change	Description	Date
Console support for Requester Pays	You can now configure your bucket for Requester Pays by using the Amazon S3 console. For more information, see Using Requester Pays buckets for storage transfers and usage.	December 31, 2012
Root domain support for website hosting	Amazon S3 now supports hosting static websites at the root domain. Visitors to your website can access your site from their browser without specifying www in the web address (for example, they can use example.com instead of www.example.com). Many customers already host static websites on Amazon S3 that are accessible from a www subdomain (for example, www.example.com). Previously, to support root domain access, you needed to run your own web server to proxy root domain requests from browsers to your website on Amazon S3. Running a web server to proxy requests introduces additional costs, operational burden, and another potential point of failure. Now, you can take advantage of the high availability and durability of Amazon S3 for both www and root domain addresses. For more information, see Hosting a static website using Amazon S3 .	December 27, 2012
Console revision	Amazon S3 console has been updated. The documentation topics that refer to the console have been revised accordingly.	December 14, 2012

Change	Description	Date
Support for Archiving Data to S3 Glacier	<p>Amazon S3 now supports a storage option that enables you to utilize S3 Glacier's low-cost storage service for data archival. To archive objects, you define archival rules identifying objects and a time frame when you want Amazon S3 to archive these objects to S3 Glacier. You can easily set the rules on a bucket using the Amazon S3 console or programmatically using the Amazon S3 API or AWS SDKs.</p> <p>For more information, see Managing your storage lifecycle.</p>	November 13, 2012
Support for Website Page Redirects	<p>For a bucket that is configured as a website, Amazon S3 now supports redirecting a request for an object to another object in the same bucket or to an external URL. For more information, see (Optional) Configuring a webpage redirect.</p> <p>For information about hosting websites, see Hosting a static website using Amazon S3.</p>	October 4, 2012
Support for Cross-Origin Resource Sharing (CORS)	<p>Amazon S3 now supports Cross-Origin Resource Sharing (CORS). CORS defines a way in which client web applications that are loaded in one domain can interact with or access resources in a different domain. With CORS support in Amazon S3, you can build rich client-side web applications on top of Amazon S3 and selectively allow cross-domain access to your Amazon S3 resources. For more information, see Using cross-origin resource sharing (CORS).</p>	August 31, 2012
Support for Cost Allocation Tags	<p>Amazon S3 now supports cost allocation tagging, which allows you to label S3 buckets so you can more easily track their cost against projects or other criteria. For more information about using tagging for buckets, see Using cost allocation S3 bucket tags.</p>	August 21, 2012

Change	Description	Date
Support for MFA-protected API access in bucket policies	<p>Amazon S3 now supports MFA-protected API access, a feature that can enforce AWS Multi-Factor Authentication for an extra level of security when accessing your Amazon S3 resources. It is a security feature that requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information, go to AWS Multi-Factor Authentication. You can now require MFA authentication for any requests to access your Amazon S3 resources.</p> <p>To enforce MFA authentication, Amazon S3 now supports the <code>aws:MultiFactorAuthAge</code> key in a bucket policy. For an example bucket policy, see Requiring MFA.</p>	July 10, 2012
Object Expiration support	You can use Object Expiration to schedule automatic removal of data after a configured time period. You set object expiration by adding lifecycle configuration to a bucket.	27 December 2011
New Region supported	Amazon S3 now supports the South America (São Paulo) Region. For more information, see Accessing and listing an Amazon S3 bucket .	December 14, 2011
Multi-Object Delete	Amazon S3 now supports Multi-Object Delete API that enables you to delete multiple objects in a single request. With this feature, you can remove large numbers of objects from Amazon S3 more quickly than using multiple individual DELETE requests. For more information, see Deleting Amazon S3 objects .	December 7, 2011
New Region supported	Amazon S3 now supports the US West (Oregon) Region. For more information, see Buckets and Regions .	November 8, 2011
Documentation Update	Documentation bug fixes.	November 8, 2011

Change	Description	Date
Documentation Update	<p>In addition to documentation bug fixes, this release includes the following enhancements:</p> <ul style="list-style-type: none">• New server-side encryption sections using the AWS SDK for PHP and the AWS SDK for Ruby (see Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)).• New section on creating and testing Ruby samples (see Using the AWS SDK for Ruby - Version 3).	October 17, 2011
Server-side encryption support	<p>Amazon S3 now supports server-side encryption. It enables you to request Amazon S3 to encrypt your data at rest, that is, encrypt your object data when Amazon S3 writes your data to disks in its data centers. In addition to REST API updates, the AWS SDK for Java and .NET provide necessary functionality to request server-side encryption. You can also request server-side encryption when uploading objects using the AWS Management Console. To learn more about data encryption, go to Using Data Encryption.</p>	October 4, 2011

Change	Description	Date
Documentation Update	<p>In addition to documentation bug fixes, this release includes the following enhancements:</p> <ul style="list-style-type: none">Added Ruby and PHP samples to the Making requests section.Added sections describing how to generate and use presigned URLs. For more information, see Sharing objects with presigned URLs and Sharing objects with presigned URLs.Updated an existing section to introduce AWS Explorers for Eclipse and Visual Studio. For more information, see Developing with Amazon S3 using the AWS SDKs, and explorers.	September 22, 2011
Support for sending requests using temporary security credentials	<p>In addition to using your AWS account and IAM user security credentials to send authenticated requests to Amazon S3, you can now send requests using temporary security credentials you obtain from AWS Identity and Access Management (IAM). You can use the AWS Security Token Service API or the AWS SDK wrapper libraries to request these temporary credentials from IAM. You can request these temporary security credentials for your own use or hand them out to federated users and applications. This feature enables you to manage your users outside AWS and provide them with temporary security credentials to access your AWS resources.</p> <p>For more information, see Making requests.</p> <p>For more information about IAM support for temporary security credentials, see Temporary Security Credentials in the <i>IAM User Guide</i>.</p>	August 3, 2011

Change	Description	Date
Multipart Upload API extended to enable copying objects up to 5 TB	<p>Prior to this release, Amazon S3 API supported copying objects of up to 5 GB in size. To enable copying objects larger than 5 GB, Amazon S3 now extends the multipart upload API with a new operation, <code>Upload Part (Copy)</code>. You can use this multipart upload operation to copy objects up to 5 TB in size. For more information, see Copying objects.</p> <p>For conceptual information about multipart upload API, see Uploading and copying objects using multipart upload.</p>	June 21, 2011
SOAP API calls over HTTP disabled	<p>To increase security, SOAP API calls over HTTP are disabled. Authenticated and anonymous SOAP requests must be sent to Amazon S3 using SSL.</p>	June 6, 2011
IAM enables cross-account delegation	<p>Previously, to access an Amazon S3 resource, an IAM user needed permissions from both the parent AWS account and the Amazon S3 resource owner. With cross-account access, the IAM user now only needs permission from the owner account. That is, If a resource owner grants access to an AWS account, the AWS account can now grant its IAM users access to these resources.</p> <p>For more information, see Creating a role to delegate permissions to an IAM user in the <i>IAM User Guide</i>.</p> <p>For more information on specifying principals in a bucket policy, see Principals.</p>	June 6, 2011
New link	<p>This service's endpoint information is now located in the <i>AWS General Reference</i>. For more information, go to Regions and Endpoints in the AWS General Reference.</p>	March 1, 2011

Change	Description	Date
Support for hosting static websites in Amazon S3	Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, <code>http://mywebsite.com/subfolder</code>) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3 .	June 6, 2011
This service's endpoint information is now located in the <i>AWS General Reference</i> . For more information, go to Regions and Endpoints in the AWS General Reference .	March 1, 2011	
Support for hosting static websites in Amazon S3	Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, <code>http://mywebsite.com/subfolder</code>) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3 .	February 17, 2011

Change	Description	Date
Response Header API Support	The GET Object REST API now allows you to change the response headers of the REST GET Object request for each request. That is, you can alter object metadata in the response, without altering the object itself. For more information, see Downloading objects .	January 14, 2011
Large object support	Amazon S3 has increased the maximum size of an object you can store in an S3 bucket from 5 GB to 5 TB. If you are using the REST API, you can upload objects of up to 5 GB in a single PUT operation. For larger objects, you must use the Multipart Upload REST API to upload objects in parts. For more information, see Uploading and copying objects using multipart upload .	December 9, 2010
Multipart upload	Multipart upload enables faster, more flexible uploads into Amazon S3. It allows you to upload a single object as a set of parts. For more information, see Uploading and copying objects using multipart upload .	November 10, 2010
Canonical ID support in bucket policies	You can now specify canonical IDs in bucket policies. For more information, see Bucket policies and user policies	September 17, 2010
Amazon S3 works with IAM	This service now integrates with AWS Identity and Access Management (IAM). For more information, go to AWS services that work with IAM in the <i>IAM User Guide</i> .	September 2, 2010
Notifications	The Amazon S3 notifications feature enables you to configure a bucket so that Amazon S3 publishes a message to an Amazon Simple Notification Service (Amazon SNS) topic when Amazon S3 detects a key event on a bucket. For more information, see Setting Up Notification of Bucket Events .	July 14, 2010

Change	Description	Date
Bucket policies	Bucket policies are an access management system that you use to set access permissions across buckets, objects, and sets of objects. This functionality supplements and in many cases replaces access control lists. For more information, see Bucket policies and user policies .	July 6, 2010
Path-style syntax available in all Regions	Amazon S3 now supports the path-style syntax for any bucket in the US Classic Region, or if the bucket is in the same Region as the endpoint of the request. For more information, see Virtual Hosting .	June 9, 2010
New endpoint for Europe (Ireland)	Amazon S3 now provides an endpoint for Europe (Ireland) : http://s3-eu-west-1.amazonaws.com .	June 9, 2010
Console	You can now use Amazon S3 through the AWS Management Console. You can read about all of the Amazon S3 functionality in the console in the Amazon Simple Storage Service User Guide.	June 9, 2010
Reduced Redundancy	Amazon S3 now enables you to reduce your storage costs by storing objects in Amazon S3 with reduced redundancy. For more information, see Reduced Redundancy Storage .	May 12, 2010
New Region supported	Amazon S3 now supports the Asia Pacific (Singapore) Region. For more information, see Buckets and Regions .	April 28, 2010
Object Versioning	This release introduces object versioning. All objects now can have a key and a version. If you enable versioning for a bucket, Amazon S3 gives all objects added to a bucket a unique version ID. This feature enables you to recover from unintended overwrites and deletions. For more information, see Versioning and Using Versioning .	February 8, 2010

Change	Description	Date
New Region supported	Amazon S3 now supports the US West (N. California) Region. The new endpoint for requests to this Region is <code>s3-us-west-1.amazonaws.com</code> . For more information, see Buckets and Regions .	December 2, 2009
AWS SDK for .NET	AWS now provides libraries, sample code, tutorials, and other resources for software developers who prefer to build applications using .NET language-specific API operations instead of REST or SOAP. These libraries provide basic functions (not included in the REST or SOAP APIs), such as request authentication, request retries, and error handling so that it's easier to get started. For more information about language-specific libraries and resources, see Developing with Amazon S3 using the AWS SDKs, and explorers .	November 11, 2009

AWS Glossary

For the latest AWS terminology, see the [AWS glossary](#) in the *AWS Glossary Reference*.
